The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 15th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer.

In sending applications stamps should be enclosed for forwarding.

059 Mechanical engineer and chief draftsman in the engineering department of large industrial concern. Prefer man who has had several years experience in design and application of coal and ore handling apparatus, ore and slag crushers and blast furnaces; steel, brick and wood buildings, bridge work and general steam and power plant engineering. Name confidential, apply by letter.

088 Assistant works manager for firm manufacturing cranes and electrical specialties; A-1 man with engineering experience in structural, mechanical and electrical work, and previous work in connection with modern manufacturing methods. Location Michigan. Apply through Society.

093 Experienced mechanical draftsman, capable of doing some designing; one preferred with experience in machine tool and shop practice and with a fair technical knowledge. Location Connecticut.

099 Professor of mechanical engineering for Southern University. Apply by letter.

0101 A large manufacturing concern wishes to engage as employment head, a man of special ability in the selection of labor, to be permanently located at the factory. Should be able to select men of proper character, who would have the training for the different classes of work carried on in the various departments. Apply by letter stating age, experience in full, and salary wanted. Location Philadelphia. Name confidential.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period.

E-72 Junior, M.E. graduate Lehigh University, several years experience as draftsman, chief engineer's assistant,

foreman and manager, at present located in prominent technical institution in New York, desires summer position which would afford experience in the mechanical field. Salary and location immaterial.

E-73 Junior member, age 26, Brown University graduate with experience in the design and inspection of power plant construction, desires position where experience in testing and operation can be obtained.

E-74 Member, age 34, technical education, married, with broad experience with leading engineers in the East on the design of steam power plants, heating and fire protection systems and inspection of mill and power plant construction and equipment, desires position with large manufacturing or engineering concern; at present employed as superintendent of construction on large mill and power plant.

E-75 Member with wide experience in the design of all manufactures of engines and power plant work, desires position with company engaged in gas or steam engineering; would also consider offer with a consulting engineer.

E-76 Member, graduate mechanical engineer, 20 years experience as designer and chief draftsman with leading manufacturers of simplex and duplex steam pumps, desires position.

E-77 Graduate M.E., age 39, 15 years consecutive and successful experience from shop apprentice to agency manager; with one large corporation nine years, manufacturing steam and producing gas engines, producer transmission and special machinery; has held positions as draftsman, designer, estimator, sales engineer, mechanical engineer and agency manager; also experienced in efficiency engineering. At present employed but desires change.

E-78 Associate-member, Stevens graduate, age 27, has had practical experience in all departments of gas engine manufacture, designing, machine work, assembling, testing and sales work, desires position as assistant to factory manager or to superintendent. Will begin at salary of \$1500. At present employed.

E-79 Stevens graduate, 1883, with experience as superintendent of bridges and buildings, and one who has specialized in railroad shop design, construction and equipment, desires position.

E-80 Member, sales engineer, thoroughly familiar with business methods and present conditions of Scandinavian countries and Russia, desires to represent firms manufacturing machine tools, power and transmission machinery, small tools and general supplies.

E-81 Member, graduate Massachusetts Institute of Technology, 1901, age 35, married, desires position about May 1st as works manager or general superintendent of large manufacturing plant; experience as such covers about 12 years. Familiar with up-to-date methods of shop management. Has successfully handled from 1000 to 1500 men.

E-82 Member, technical graduate, age 36, mechanical and electrical engineer thoroughly practical, original and efficient, 13 years experience in responsible capacity, designing, manufacturing and selling water turbines, governors, penstocks and accessories for hydro-electric installations; also experienced in making preliminary surveys, reports, efficiency tests and investigations of power propositions, writing specifications and purchasing material, desires position where these qualifications, coupled with executive ability are desirable. With present employer 12 years. Location preferably East or South.

E-83 Associate-member, age 42, experienced in superintending masonry, concrete, brick and steel construction, also installation and maintenance of mill machinery, drafting, foundry, forge, pattern, machine and bridge shop-work, desires position.

E-84 Associate-member, engineering graduate, experienced in general engineering and teaching, desires position for the coming academic year in mechanical department of a technical school.

E-85 Junior member, age 31, considerable experience in foundry and core room operation, equipment design and installation, pattern making, foundry costs, etc., wishes position with large company operating malleable or grey iron foundries. At present employed.

E-86 Member with broad and thorough manufacturing experience from apprentice to general manager in foundry, pattern, machine, blacksmith, boiler shops and drawing office, positions which called for initiative executive ability, tact, the handling of correspondence, organization of men and the direction of their work, wishes employment as manager, superintendent or other executive position. Location immaterial.

E-87 Member, 25 years valuable and complete experience in design and construction of electric traveling cranes, rolling mill machinery, special machinery, etc., desires position as chief designing or mechanical engineer, or in any other capacity where experience would be of value.

E-88 Mechanical engineer, Stevens graduate, age 30, married, seven years varied experience having specialized in pressed steel, both light and heavy; at present holding responsible executive position as plant engineer with small manufacturing concern. Desires a position along similar lines, or one as assistant to superintendent or manager with company offering opportunity for advancement.

E-89 Member, Cornell graduate, age 38, married, nine and one half years experience in railroad shop, testing laboratory, drafting, supervision of power plant and foremen; two years construction work, design and installation of equipment in steel mills, desires position in mechanical department of railroad, manufacturing concern or firm of engineers.

E-90 Factory superintendent or general foreman with broad experience in modern manufacturing methods can produce results with equipment; 12 years experience with production efficiency, organizing, designing tools, and labor saving devices for decreasing of costs.

E-91 Member, technical graduate, with wide experience in design and supervision of heat, light and power plants, also eight years experience in efficiency engineering desires position with consulting engineer or with private firm.

E-92 Junior member, M.E., command of the English and German languages, some knowledge of typewriting and stenography, three years in charge of the mechanical laboratory in a University in the middle West seeks a position with a firm with opportunity for advancement; willing to start at the bottom and work up. Location Eastern states.

E-93 Sales engineer, age 30, married, with wide acquaintance in the South Eastern states, experienced in handling steam, gas, hydraulic and electrical equipment for largest builder in America wishes to locate permanently in his native South in capacity of district manager, or sales agent for similar or allied lines. At present employed but desires change solely for personal reasons.

E-94 Member with experience as superintendent and factory manager thoroughly familiar with modern methods in manufacturing, efficient shop organization and management, desires position.

E-95 Junior member, graduate in mechanical and chemical engineering, four years teaching experience and summer work in power plant, irrigation work, etc., desires position in mechanical-chemical industry. Available after June 15.

E-96 Junior member, graduate mechanical engineer, post graduate work in management and efficiency engineering at Harvard University; drafting room, pattern and machine shop experience, desires position as assistant to works manager or superintendent with an opportunity for advancement by conscientious work and the proper initiative in superintending and increasing the efficiency of production.

E-97 Junior, technical graduate, possessing executive ability, 12 years varied experience in design, construction, operation and maintenance of power houses and sub-stations; familiar with up-to-date methods of mapping and execution of construction and repair orders in power plant and mill accessories, experienced in testing and experimental work, desires position of power engineer, assistant superintendent, assistant manager or works manager. At present employed. Location preferred, New York or vicinity.

E-98 Student member and technical graduate desires employment with engineering or manufacturing company; willing to start in right position at low salary.

E-99 Junior member, mechanical engineer, University of Illinois graduate, age 25, with thorough knowledge of foundry, core and machine shop methods and details, experienced in cost and efficiency work, sales, purchasing, etc., desires position as works manager, or as assistant manager of sales.

E-100 Associate-member, graduate mechanical engineer, 12 years general engineering experience as designer, erection superintendent, assistant general superintendent, consulting and efficiency engineer, would consider position as chief engineer, works manager or similar responsible position with progressive concern.

E-101 Member, 34, married, technical education, 14 years experience in the design, erection and efficient operation of power plants, for past eight years with consulting engineer as principal assistant; up-to-date boiler-room management and efficiency use of exhaust steam a specialty, desires position as mechanical engineer with manufacturing plant, central station or consulting engineer. Location preferred, Eastern states.

E-102 Young man, technical graduate, experienced in engineering, advertising, sales, and practical experience covering power plant operation, foundry, machine shop work and drafting room practice, desires position in advertising or sales department. Salary secondary consideration.

E-103 Mechanical engineer, 1914 graduate, desires position with manufacturing concern or consulting engineers. Will consider any offer with chance for advancement.

E-104 Technical graduate, three years experience in construction work, capable of handling men, would like to get in touch with master mechanic or chief engineer of large manufacturing concern or power company.

E-105 Member, technical graduate, wide training and experience in design of power plants and machinery, construction, maintenance and operation, purchasing engineering material, executive charge of all consulting engineering work, including building construction of all kinds, desires position as works manager or superintendent.

E-106 Member, 25 years practical experience in the design and manufacture of the highest grade of fine interchangeable work. At present employed with one of the largest concerns of its kind in the world as mechanical expert. New York or vicinity preferred.

E-107 Associate-member, age 37, married, with technical training and 17 years practical experience as machinist, draftsman, machine shop foreman and three years instructor of machine shop practice, mechanical drawing and shop mathematics, would consider position for the coming academic year.

mic year in technical high school or engineering college. At present employed in a large city vocational school.

E-108 Junior member, seven years experience in economies relating to plant operation, costs, and mechanical and electrical equipment; expert on reports, plans and specifications; writes well on technical and commercial subjects.

E-109 Designing engineer, technical graduate in mechanical engineering, three years practical experience in designing work, has been employed as chief draftsman in high speed steam engine industry and in small factory building, high grade gasoline motors. Now employed in engineering department of large motor car company.

E-110 Mechanical engineer, member, age 38, with shop, designing, sales, executive and business experience desires permanent connection with manufacturer, preferably in Eastern states. Can handle engineering sales, sales office, or executive work in jobbing shops.

E-111 Member, technical graduate, broad experience in factory production work, design, construction and operation of water filtration and sewage disposal plants, consulting engineer, three years experience as district sales engineer, desires position as superintendent or sales manager.

E-112 Mechanical engineer, good personality and character, successful as organizer, executive and production engineer; thorough knowledge and experience in the principles of efficient management, has been associated with best professional exponents of scientific management; fifteen years experience as superintendent, seeks position as factory manager, superintendent or special organizer. At present engaged but desires change.

E-113 Member, A.S.M.E. and A.I.E.E., age 35, technical graduate, E.E. and M.S., 11 years practical experience in the design, construction, operation and maintenance of hydro-electric and steam electric plants, high tension transmission and distribution of electrical energy to mines and cities; estimates, investigations and reports, desires position where experience of this nature will be of advantage. Location immaterial, salary secondary.

E-114 Junior member, age 27, technical graduate, four years experience as mechanical engineer on ore and coal handling machinery, cranes, hoists, monorails and parabolic bins; also experienced in the design of water turbines and similar heavy machinery, desires position as mechanical engineer or estimator with concern who could use man of this experience.

E-115 Member, technically trained, seven years experience in mechanical engineering in foundry machine shop and brass rolling mill work; also ten years with large firm of shipbuilders as leading hull draftsman, inspector and outside man, desires position with engineering firm, or as assistant to superintendent of hull construction at a shipyard. At present employed as mechanical engineer for leading foundry.

E-116 Junior, technical graduate, nine years experience in the design and construction of steam power plants and general engineering, executive charge of the installation of turbine units for municipal lighting and railway service, desires position of similar character such as mechanical engineer for a consulting firm, engineer of construction or power engineer.

E-117 Associate-member A.S.M.E. and A.S.C.E., 13 years experience on design and construction of industrial plants, buildings and bridges, desires position of responsibility in New York or vicinity.

E-118 Student member, Cornell graduate, age 28, married, eight years experience as practical mechanic, toolmaker, master mechanic and tool inspector, desires position with opportunity for advancement, preferably in experimental

work, testing, design or as instructor in physics or experimental engineering. At present employed.

E-119 Associate-member, age 30, 15 years practical experience as experimental model maker, draftsman, foreman and production engineer. Experienced as designer on metal working machines and tools. Broad practical experience as factory systematizer having served as junior for one of the foremost industrial engineers in the country, desires position as industrial engineer, superintendent or assistant manager. At present employed as efficiency engineer in plant manufacturing small interchangeable parts.

E-120 Junior, technical graduate, energetic young sales engineer, six years experience in engineering and selling special steel castings, desires position in executive or sales office with a management corporation.

E-121 Graduate M.E., young man with eight years experience as special engineer, superintendent and works manager, 150-300 men. Specialized in production, efficiency and cost methods in the foundry, machine shop and assembly department on both jobbing and repetitive manufacture. Correlative executive experience in plant construction and equipment. Present salary \$3,800.

E-122 Member, technical graduate, with commercial training, speaking five languages, fully conversant with Latin and South American trade conditions, 18 years varied experience in design and construction of machinery and buildings, remodeling, maintenance and operation of industrial plants and equipment; systematizing of shops and processes along scientific management lines, testing and general plant engineering; familiar with handling men, drawing up contracts, purchasing equipment and material, appraising properties, modern methods of manufacturing and marketing products, desires to become identified with manufacturing or industrial plant in responsible administrative or executive position. At present employed.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the Libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Report of the Committee to formulate standard specifications for the construction of steam boilers and other pressure vessels and for care of same in service known as The Boiler Code Committee. Rules for the Construction of stationary boilers and for allowable working pressures, 1914. Gift of A.S.M.E.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Year Book 1915. *New York, 1915.* Gift of A.S.M.E.

AUTOMOBILE CLUB OF AMERICA. Year Book 1914. *New York, 1914.* Gift of Club.

CARNEGIE FOUNDATION FOR THE ADVANCEMENT OF TEACHING. Case Method in American law schools. Bulletin no. for 1914. Gift of Carnegie Foundation for the Advancement of Teaching.

DESIGN OF BOILERS AND PRESSURE VESSELS, G. B. HAVEN and G. W. Sweet. *New York, J. Wiley & Sons, 1915.* Gift of publishers.

DRY ROT IN FACTORY TIMBERS, 1915. *Boston, 1915.* Gift of Associated Factory Mutual Fire Insurance Companies.

HANCOCK'S APPLIED MECHANICS FOR ENGINEERS. Revised and rewritten by N. C. Riggs. *New York, The Macmillan Co., 1915.* Gift of publishers.

This is intended as a textbook for engineering students of the junior year. Originally prepared by Professor E. L. Hancock of Purdue University, Professor Riggs has revised the text, introducing much larger use of graphic methods. W. P. C.

HOW TO FINANCE A BUSINESS. 202 proved methods of raising capital. *Chicago, A. W. Shaw Co., 1912.* Gift of publishers.

A very careful analysis of methods of financing, giving bases of credit and general financial methods leading to success. W. P. C.

INSTRUCTION PAPERS ON FOUNDRY PRACTICE, THOS. D. WEST, Gift of author.

MOTORTANKSCHIFF "WOTAN," Gift of W. R. Haynie.

NEW YORK BOARD OF ESTIMATE AND APPORTIONMENT, Monthly Bulletin of Tests made in Laboratories conducted by the City of New York upon samples taken from Deliveries of Materials and Supplies, Dec. 1914. Gift of Board of Estimate and Apportionment.

PENNSYLVANIA WATER SUPPLY COMMISSION, Annual Report, 1913. *Harrisburg, 1914*. Gift of Pennsylvania Water Supply Commission.

PRINTED ENGINEERING RESOURCES, J. M. Tollesh, Reprinted from Bulletin of the Society for the Promotion of Engineering Education, vol. 5, Nov. 1914. Gift of author.

RAILWAY ECONOMICS, A collective catalogue of books in fourteenth American libraries, *Chicago, University of Chicago, 1912*. Gift of Bureau of Railway Economics.

SEAL OF SAFETY, 1914, 1915. Year book of Max Aids Machine Co. Gift of Julius Brezniger.

SPEERY GYRO-COMPASS AND NAVIGATION EQUIPMENT, Ed. 2. *New York, 1912*. Gift of Elmer A. Speery.

SPRINGFIELD (MASS.) WATER COMMISSIONERS, Forty-first Annual Report, 1914. *Springfield, 1915*. Gift of Water Commissioners.

UNIVERSIDAD NACIONAL DE LA PLATA, Contribución al Estudio de las Ciencias físicas y matemáticas. (Serie Técnica, Vol. I, no. 1.) *La Plata, 1915*. Gift of Universidad Nacional de La Plata.

THE SPRING MEETING

BUFFALO, JUNE 22 to 25

CITY HALL, BUFFALO

THE complete program of the Spring Meeting at Buffalo is published in this number and it is evident that there is not only an attractive group of papers, but that socially the meeting will afford a period of rare enjoyment to those who accept the hospitality of the Buffalo engineers.

Buffalo is not only a city whose industries have developed remarkably during the past few years and thus are of unusual interest to visiting engineers, but it is a city of beautiful avenues and parks and is always attractive to the visitor. Its proximity to Niagara Falls adds still further to the opportunities for pleasure during a stay in the city, and the Local Committee have perfected plans so that every one may enjoy to the utmost the attractions which Buffalo and its environs provide.

It will be noted from the program that there are three periods for professional sessions, on Wednesday, Thursday and Friday-mornings, leaving the afternoons free for excursions.

On Tuesday evening there will be interesting addresses of welcome and response respectively by Mr. Frank B. Baird of Buffalo and Dr. John A. Brashear, President of the Society, and refreshments will be

served by the local members of the Society and the members of the Engineering Society of Buffalo.

The day Wednesday will be spent at Niagara Falls, the party going there by special electric cars and holding its morning session in the auditorium of the Shredded Wheat Biscuit Company's factory. The return trip will be in time for dinner in Buffalo and an evening lecture by Dr. F. H. Newell, formerly Chief of the United States Reclamation Service, who will speak on the Engineer as a Citizen and illustrate his address with beautiful colored lantern slides.

On Thursday, besides various excursions, the ladies are to be entertained by an automobile trip, and tea is to be served by the Twentieth Century Woman's Club, to which both the members and the ladies are invited. In the evening there will be the reception and dance, when there will be an opportunity to meet socially many of the people in Buffalo.

It is expected that a delegation from Cleveland will come by boat and will be present during the day Thursday.

On Friday afternoon there will be still further opportunities offered for visits to points of engineering interest.

The arrangements for the meeting have been in the hands of the Meetings Committee, John H. Barr, Chairman, and several Buffalo committees, the chairmen of which are as follows: David Bell, General Committee; D. W. Sowers, Finance Committee; H. P. Parrock, Reception Committee; David C. Howard, Entertainment Committee; W. H. Carrier, Hotel Committee; John Younger, Printing and Publicity Committee; Mrs. William Henry Barr, Ladies Committee.

The time for the meeting is such that the commencement season of the colleges will be over, so that a large representation of college men is expected, and it is believed that the accessibility of Buffalo from sections of the country where a large percentage of the membership of the Society is located, will result in a large attendance. It is assured that every member who attends will feel well repaid and count the meeting as a time of great profit and pleasure.

PROGRAM OF THE SPRING MEETING

HEADQUARTERS AT HOTEL STATLER, JUNE 22 TO 25

Tuesday, June 22, Buffalo

2:00 p.m. Opening of headquarters and registration.

Mezzanine Floor

6:00 p.m. Conference and dinner of officers and representatives of local sections and the Local Sections Committee.

8:30 p.m. Informal reception and reunion.

Ball Room, Second Floor

An address of welcome will be made by Mr. Frank B. Baird, representing the industries of Buffalo, to which Dr. John A. Brashear, President of the Society, will respond. The evening will afford an opportunity for the reunion of members and their reception by the Buffalo engineers. Refreshments will be served.

Wednesday, June 23, Niagara Falls

9:00 a.m. The party will leave Hotel Statler by special trolley cars for Niagara Falls. Price for the round trip, including the Gorge Route, \$1.25.

10:30 a.m. Business Meeting. Report of Tellers on Amendment to Constitution. Presentation from the Council of proposed amendments to C' 53 and C' 48 of the Constitution. Reports of professional committees.

Auditorium of The Shredded Wheat Co.'s Factory

PROFESSIONAL SESSION FOLLOWING BUSINESS MEETING

THE STUDY OF A SHAFT AND ITS IMPROVEMENT BY HEAT TREATMENT, John Younger

A COMPARISON OF THE PROPERTIES OF NICKEL, CARBON AND MANGANESE STEEL, Robert R. Abbott

USE OF CORRUGATED FURNACES FOR VERTICAL FIRE-TUBE BOILERS, F. W. Dean

ON MEASURING GAS WEIGHTS, Thos. E. Butterfield.

During the morning the ladies will have time at their disposal to visit the Shredded Wheat Company's factory and the plant of the Falls Chocolate Company, as well as to enjoy the outdoor surroundings of the Federal Reservation at the brink of the Falls.

1:00 p.m. Luncheon at the International Hotel, price 75 cents.

Wednesday Afternoon, Niagara Falls

2:30 p.m. Special cars will be provided for those who desire to take the Gorge Route trip, the price for which is included in the round-trip ticket from Buffalo. There will be an opportunity for those who do not take this trip to inspect the power plants both on the Canadian and American sides, or to enjoy the scenic beauties of Niagara Falls and Goat Island.

5:00 p.m. The special cars for Buffalo will leave the International Railway Station.

Wednesday Evening, Buffalo

8:30 p.m. Illustrated lecture on "The Engineer as a Citizen," by Dr. F. H. Newell, formerly Chief of the U. S. Reclamation Service.

Ball Room, Second Floor, Hotel Statler

Thursday, June 24, Buffalo

10:00 a.m. Simultaneous professional sessions.

PROFESSIONAL SESSION

Ball Room, Second Floor, Hotel Statler

RATIONAL DESIGN AND ANALYSIS OF HEAT TRANSFER APPARATUS, E. E. Wilson

INFLUENCE OF DISK FRICTION ON TURBINE PUMP DESIGN, F. ZIR Nedden

SURFACE CONDENSERS, C. F. BRARR

SIMULTANEOUS SESSION

Assembly Room, Second Floor, Hotel Statler

SOME MECHANICAL FEATURES OF THE HYDRATION OF PORTLAND CEMENT AND THE MAKING OF CONCRETE AS REVEALED BY MICROSCOPIC STUDY, Nathan C. Johnson

DESIGN OF RECTANGULAR CONCRETE BEAMS, Howard Harding

MODEL EXPERIMENTS AND THE FORMS OF EMPIRICAL EQUATIONS, Edgar Buckingham

THE EFFECT OF RELATIVE HUMIDITY ON AN OAK TANNED LEATHER BELT, W. W. Bird and F. W. Roys

11:00 a.m. Automobile ride for the ladies through the city and its environs and the park system.

Thursday Afternoon, Buffalo

2:00 p.m. Council Meeting.

Assembly Room, Second Floor, Hotel Statler

2:00 p.m. Parties will leave the hotel to visit manufacturing plants and points of interest.

5:00 p.m. Tea will be served for the ladies and members by the Twentieth Century Woman's Club at their Club House, 495 Delaware Avenue.

Thursday Evening, Buffalo

9:00 p.m. Reception and dance.

Ball Room, Second Floor, Hotel Statler

This will be the leading social function of the Spring Meeting. It is expected that many residents of Buffalo will attend as well as their visiting friends. A collation will be served. Invitations will be sent to all who register at headquarters, which, to be valid, must be endorsed at the registration desk and for which there will be a charge of \$2.50 per person.

Friday, June 25, Buffalo

10:00 a.m. Professional Session.

Ball Room, Second Floor, Hotel Statler

LAWS OF LUBRICATION OF JOURNAL BEARINGS, M. D. Hersey

EXPENSE DISTRIBUTION, H. L. Gantt

LAPS AND LAPPING, W. A. Knight

This is the last session, but it is planned that any who desire may visit manufacturing plants during the afternoon and the Local Committee will be pleased to provide guides for this purpose.

PAPERS FOR THE SPRING MEETING

Brief abstracts of the papers for the Spring Meeting which had been assigned up to the time of going to press were printed in the last number of *The Journal*. In this issue the complete list of papers is given in the program and abstracts follow of those which were not

A COMPARISON OF THE PROPERTIES OF NICKEL,
CARBON AND MANGANESE STEEL

BY ROBERT H. ABBOTT

This paper gives a comparison of the physical properties, both in the annealed and heat-treated state, of three steels of the same carbon contents, the first of which is an ordinary

ALBRIGHT ART GALLERY

ONE OF THE LARGEST AND MOST ATTRACTIVE IN THE UNITED STATES

HISTORICAL SOCIETY'S BUILDING

STONE ARCH BRIDGE

SCENES IN DELAWARE PARK, ONE OF BUFFALO'S BEAUTIFUL PARK CENTERS

listed in the May number. These papers are of a high order of merit and are miscellaneous in character, treating a variety of subjects. All of these papers will be printed in pamphlet form for distribution in advance of the meeting and copies of any or all of them will be sent gratis to members applying to the *Secretary* prior to the meeting. Application should be made as soon as possible to insure delivery before the meeting. After the meeting extended abstracts of the papers and an account of the proceedings, with discussion, will appear in *The Journal* so that members will have early information concerning the events of the meeting. Finally, the papers, together with the discussion, will be printed in complete form in the annual volume of *Transactions* for 1915 for permanent reference.

carbon steel, the second a nickel steel, and the third a manganese steel containing 1.6 per cent manganese.

Test bars of each kind were quenched from slightly above the upper critical points and were then reheated, or drawn at varying temperatures from 300 deg. Fahr. to 1300 deg. Fahr. The results of these tests are given in the form of charts for comparison. The elastic limit, maximum strength, reduction in area, elongation and Brinell hardness are compared. Equations are developed, giving these results in terms of the temperature of draw.

Tests were then made comparing the effects produced upon the physical properties by quenching from various temperatures above and below the upper critical points. These results are given in the form of charts.

CONCLUSIONS: In the three steels under comparison, it required three times as much nickel as it did of manganese to give the same increase in physical strength. In the ni-

The Whole Day Wednesday, June 23, will be Spent at

heat-treated steels, the increase in strength was not accompanied by a decrease in toughness; rather the reverse. In the heat treated steels this increase in strength is accompanied by an increase in toughness, with the nickel steel, while with the manganese steel it is accompanied by a decrease in toughness.

ON MEASURING GAS WEIGHTS

BY THOMAS E. BUTTERFIELD

The author believes that gas quantities should be expressed in weight rather than in volume measure. Where the performance of different sets of apparatus for generating, burning, compressing or exhausting gas is to be justly compared, density must be determined. This makes it natural to express quantity as weight, volume measures also being given, but as of subordinate interest.

It is also suggested that where chemical analysis is used to determine the proportions of the various materials entering a combustion process, a method of computation be standardized which depends on the determination of the weights of each chemical element entering the reaction. An illustrative example is given.

ON THE LAWS OF LUBRICATION OF JOURNAL BEARINGS

BY M. D. HERSEY

In order to establish a rational basis for bearing design, it would be desirable to have empirical equations, or curves, showing accurately and completely how the friction loss and load-carrying power of bearings depend on all the physical conditions governing the action of lubrication, including, of course, the size, shape, and fit of the bearing, the speed, degree of lubrication, properties of the lubricant, and characteristics of the cooling system. The problem of

mapping out the laws of lubrication in this general way, whether by piecing together existing data or by making new experiments, is such a complicated one that it is worth while to stop and consider whether any general principles are available which may serve to simplify it.

A recognition of the above facts has led to the present paper, the object of which is first to reduce the problem to a physical basis by suitable definitions and restrictions, and then to develop certain general relations which will simplify the solution of the problem. These relations are of two sorts and may be summarized as follows:

a The general forms of the laws of lubrication are deduced by dimensional reasoning, and the characteristic properties of dynamically similar bearings are discussed in the paper.

b A distinction is pointed out between the "characteristic" i.e. purely dynamical equations, and the "working" equations needed in the final design of a bearing. It is then shown that the dynamical characteristics of the bearing, and the thermal characteristics of the lubricant and the cooling system are three independent parts of the problem which may be separately investigated, thus greatly diminishing the number of combinations of conditions needed for mapping out the laws of lubrication over the full range of all the variables involved. Finally a general method has been outlined for deducing the desired working equations by utilizing the results of these three investigations as shown.

The paper closes with an analysis of the "ideal bearing," i.e. one which is perfectly circular in cross section, etc. In this connection Sommerfeld's results are reproduced in a convenient form for practical use, and extended by a treatment of heating effects. While intended primarily as a particular illustration of the foregoing general relations, the equations and curves of the ideal bearing doubtless afford a first approximation to the laws of lubrication of actual bearings.

Niagara Falls Where the first Professional Session will be held

EXCURSIONS TO INDUSTRIAL PLANTS

On Thursday and Friday afternoons there will be no professional sessions at the Spring Meeting and parties will be made up to visit the various industrial plants of Buffalo and vicinity, cordial invitations from which have been received by the Local Committee. In the last number of The Journal accounts of several of these plants were published, with illustrations of some of them, and invitations have since been extended by several firms referred to below. The list of plants to be visited includes the following: The Lackawanna Steel Company; Buffalo Foundry and Machine Company; Larkin Company, the mail-order house; Wickwire Steel Company; Pratt and Lambert Company, varnish manufacturers; Snow Steam Pump Works; Pierce-Arrow Motor Car Company; Pratt and Letchworth Company, Bingham and Taylor Company, The Aluminum Castings Company, and the D. W. Sowers Manufacturing Company, all engaged in foundry work; the Buffalo Forge Company; the Simonds Manufacturing Company, manufacturer of saws; the Roycroft Shops, East Aurora; the power plants at Niagara Falls where are also the Shredded Wheat Biscuit Company, the Falls Chocolate Company and the large number of electro-chemical industries, which latter, however, for the most part are not open to the public. Besides these firms there are the four referred to below.

AMERICAN RADIATOR COMPANY

Buffalo manufactures more heating apparatus than any other city in the world. Here are located three large plants of the American Radiator Company, and also their Institute for Thermal Research. National advertising has made their heating systems well known to almost everyone.

THE J. P. DEVINE COMPANY

The J. P. Devine Company of Buffalo has specialized in the introduction and development of the use of the vacuum drying and impregnating apparatus in this country, and its installations are extensively used in the chemical and allied industries. By reason of its extended experience in supplying standard and special equipment to the chemical industries, and because of its German connections, this company has been able to develop special facilities in supplying autoclaves, digestors, nitrating and sulphurating kettles, rectifying columns, etc., used in the manufacture of benzol, aniline, tonol and other products that have been heretofore obtained from Europe. Members of the society will be accorded a cordial reception at this plant and will find there much that is of interest.

THE CROSBY COMPANY

Buffalo is also the home of The Crosby Company, makers of sheet metal stampings for a variety of purposes, including those used in automobiles, motor cycles, bicycles, cream separators, lawn mowers, etc. In addition, they design, build and install special machinery for producing difficult pieces of metal stamping. Their plant is exceptionally large and well equipped, and should be inspected by all visiting engineers.

GOULD COUPLER COMPANY

At Depew, just outside of Buffalo, is located the plant of the Gould Coupler Company, manufacturers of railway couplers, truck frames, general steel castings, electric train lighting systems and storage batteries. The plant is a large one, giving employment to some 3000 men, and embraces production work of unusually interesting character in a variety of different lines. A cordial invitation is extended to the visiting engineers to inspect their works and it is hoped that a large number will be able to take advantage of the opportunity.

HOTELS AND TRANSPORTATION

The hotels at Buffalo recommended by the Local Committee for guests attending the Spring Meeting, with rates, are as given below. Members should make reservations by writing direct to the hotel at which they desire to stay during the convention.

HOTEL STATLER, HEADQUARTERS FOR THE SPRING MEETING

Single room with bath, \$2.50 to \$4.50.
Single room with shower bath only, \$2.00.
Double room with bath, \$4.00 to \$6.00.
Double room with shower bath only, \$3.00 to \$4.00.
Double room with tub and shower bath, \$4.00 to \$7.00.

HOTEL IROQUOIS

Single room with bath, \$3.00 to \$5.00.
Single room with shower bath only, \$2.50 to \$3.00.
Single room without bath, \$2.00 to \$3.00.
Double room with bath, \$5.00 to \$7.00.
Double room with shower bath only, \$4.00 to \$5.00.
Double room without bath, \$3.00 to \$4.00.

LAFAYETTE HOTEL

Single room with bath, \$2.50 and upwards.
Single room with shower bath only, \$2.00 and upwards.
Single room without bath, \$1.50 and upwards.
Double room with bath, \$4.00 and upwards.
Double room with shower bath only, \$3.50 and upwards.
Double room without bath, \$3.00 and upwards.

HOTEL LENOX

Single room with bath, \$2.50.
Single room without bath, \$1.50.
Double room with bath, \$3.50.
Double room without bath, \$2.50.

The Iroquois and Lafayette hotels are located near the Hotel Statler. The Hotel Lenox is a large family hotel pleasantly situated on North Street at Delaware Avenue, in the residential district. Visitors desiring to register at the latter should take a Miller Transfer Company's taxicab at the station and instruct the driver to charge the service to the hotel.

TRANSPORTATION

The present arrangements of the railroads with regard to transportation of those attending conventions are such that no material reduction can be secured, and no effort will be made by the Society to organize parties for the trip to and from Buffalo except as members going on a particular train may wish to leave their names at the Society headquarters for the benefit of others who may wish to travel on the same train. Each person will be required to pay full rate for transportation.

VOTE ON THE SOCIETY'S PUBLICATIONS

In accordance with a resolution passed at the last Annual Meeting and a subsequent resolution of the Council, a vote of the entire membership is to be taken on the question of the publications of the Society. It was expected that ballots for this purpose would have been issued before now, but it was decided to defer the

matter until a report could be made upon the publications by the Administration Committee. This Committee was appointed in January to "investigate and report back to the Council at an early date upon the economical operation of the Society's administration and also that of the Council." These investigations extend into the various activities of the Society, including the publications, looking to the greatest possible usefulness to the membership as well as the economical administration of the various departments.

In this connection it may be stated that the publication plan which is now being followed includes the publication of the annual volume of Transactions in the 6 x 9 size, as heretofore. Papers presented at the Spring and Annual Meetings are printed in pamphlet form in advance of the meeting and are sent gratis to members requesting them previous to the meeting, due announcement of the papers being made in The Journal.

Following a meeting extended abstracts of the papers are printed in The Journal, together with an account of the discussion, so that the reader may be informed promptly what transpired; and finally the complete, revised papers and discussion appear in the annual volume of Transactions.

Besides this material The Journal contains very complete accounts of the local meetings of the Society, which are now held at intervals in fourteen different cities and which bring to The Journal a large number of valuable papers secured through the efforts of the committees in different sections of the country. An important feature of these papers in relation to the membership at large is that they present the latest engineering developments in the particular locality where the meeting is held, which strengthens the national character of the Society and the comprehensive scope of the papers which it is the privilege of The Journal to publish.

Besides these varied papers The Journal contains from month to month announcements and reports of the Society's activities which, through its committees, are reaching out into broader fields of usefulness. The Journal contains also a review section, including abstracts of foreign articles, and in spite of the curtailment of foreign publications, owing to the unfortunate conditions existing at the present time, this department is able to present from month to month much valuable material on engineering practice.

COUNCIL NOTES

At the meeting of the Council on May 14, 1915, Major William H. Wiley was appointed Chairman and John A. Hill, Vice-Chairman, to represent the Society on a joint committee of the engineering societies, co-operating with the United States Government and Army in the organization of a civilian corps of engineers. These members of the committee are to choose their associates, making a committee of five.

Announcement was made of the appointment of C. M. Allen, Charles T. Main and W. M. White as a committee to consider the merits of a suggested government water wheel testing flume and to report back to the Council.

Voted: That one session of the annual meeting in New York, December 1915, be set aside for a memorial meeting to Frederick W. Taylor, and that a committee composed of Past-Presidents Henry R. Towne, Chairman, Frederick R. Hutton, Alex. C. Humphreys, John R. Freeman and Oberlin Smith, be in charge of this session, at which it is suggested one principal paper be presented to include an account of Mr. Taylor's life and the development of such phases of his work as the Committee may deem proper.

Voted: That Francis H. Richards, W. H. Boehm and H. de B. Parsons be appointed on the Committee on Expert Testimony, cooperating with the American Association for the Advancement of Science, with the request to add two other members of their own choosing.

Voted: In connection with the resolution of the Council of April 9, to refer to the Committee on Public Relations with request to report recommendations to the Council, as a "special committee of five to formulate general principles for the guidance of those who may serve the Society in a representative capacity, and particularly when dealing with public questions."

It was voted to approve an appropriation of \$250 towards the development of a Search Bureau in the Library of the United Engineering Society.

Voted: To express to H. de B. Parsons the appreciation of the Council for his report on Fire Hose Specifications, covering the result of appointment as the representative of the Society on a special committee appointed by the Fire Department of the City of New York.

The Secretary read a letter from E. G. Spilsbury reporting the action taken by the engineers committee from the several societies on the constitutional convention. Prof. A. M. Greene, Jr., also reported that the committee had appeared before the convention, that Senator Root had received them and given them a hearing, with the result that the committee is now endeavoring to have these suggestions drafted in the form of various amendments.

Voted: To approve as a committee on meetings in Philadelphia, Robert H. Fernald, Chairman, W. R. Jones, Secretary, E. B. Carter, H. E. Ehlers, J. E. Gibson and A. C. Vaulain, and to approve the appointment of F. W. Gay as a member and Secretary of the committee on meetings in San Francisco to take the place of C. T. Hutchinson who has resigned.

Professor Hutton read a letter acknowledging the receipt by the Institution of Naval Architects, of the draft for 60 pounds, being the amount subscribed by members of the Society and friends of Sir William H. White, toward a memorial fund to honor his memory.

INTERNATIONAL JURY OF AWARDS

PANAMA-PACIFIC INTERNATIONAL EXPOSITION

The group Juries of Award of the Panama-Pacific International Exposition have been in session at San Francisco during the month of May and several members of the Society have served in the various groups, of which the following is as complete a list as we have at present: Guy L. Bayley, George M. Brill, George W. Dickie, Paul Doty, John T. Faig, H. W. Hibbard, John Hunter, Charles T. Hutchinson, Wm. H. Kavanaugh, Frederick R. Low, Charles E. Lucke, Wynne Meredith, Thomas Morrin, C. P. Poole, Calvin W. Rice, Angus Sinclair, Jesse M. Smith, Bradley Stoughton and Max Toltz. The classification of the machinery exhibits is as follows:

- Group 85 Steam Generators and Motors Utilizing Steam. Accessory Appliances
- Group 86 Internal Combustion Motors.
- Group 87 Hydraulic Motors.
- Group 88 Miscellaneous Motors.
- Group 89 General Machinery and Accessories.
- Group 90 Tools for Shaping Wood and Metals.

There are three Juries for the machinery exhibits, aside from the electrical apparatus, of which the officers are as follows:

Group 85 to 88 inclusive, Charles E. Lucke, Chairman, H. W. Hibbard, Secretary.

Group 89, George M. Brill, Chairman, Calvin W. Rice, Secretary.

Group 90, George W. Dickie, Chairman, John T. Faig, Secretary.

PUBLICATION OF THE BOILER CODE

The Boiler Code which was published in pamphlet form the first of March will be sent to every member of the Society in the annual volume of Transactions, to be distributed during the coming summer. In view of its publication in Transactions and of the availability of the report in pamphlet form it is not intended to reprint the report in The Journal. Those desiring pamphlet copies may secure them at 40 cents per copy to members (and to organizations), and 80 cents per copy to non-members. These prices apply to lots of less than 1000. In lots of 1000 to 2000 the price is 30 cents per copy, and in lots of 2000 or over the price is 20 cents per copy, f.o.b. printer, Lyons, N. Y.

PORTRAIT OF ALFRED NOBLE

On April 22 a portrait of the late Alfred Noble, painted by Alphonse Longers, was unveiled at the Engineers' Club in New York. The portrait is an excellent likeness and fittingly commemorates the personality of the engineer who was so widely known among the profession throughout the country. He was a frequenter of the Engineers' Club, where he met his friends from day to day. Addresses were made at the unveiling by Stevenson Taylor, J. Waldo Smith, Professor Hutton and H. F. DuPuy.

AWARDS OF THE FRANKLIN MEDAL

The Franklin Medal, the highest recognition in the gift of The Franklin Institute, Philadelphia, has recently been awarded to Heike Kamerlingh Onnes, and to Thomas Alva Edison, Mem. Am. Soc. M. E. The awards were made on the recommendation of the Institute's Committee on Science and the Arts, that to Onnes being in recognition of his "long-continued and indefatigable labors in low-temperature research which has enriched physical science, not only with a great number of new methods and ingenious devices, but also with achievements and discoveries of the first magnitude," and that to Edison in recognition of "the value of numerous basic inventions and discoveries forming the foundation of world-wide industries, signally contributing to the well-being, comfort and pleasure of the human race."

The Franklin Medal Fund, from which this medal is awarded, was founded on January 1, 1914, by Samuel Insull. Awards of the medal are to be made annually to those workers in physical science or technology, without regard to country, whose efforts, in the opinion of the Institute, have done most to advance a knowledge of physical science or its applications.

The present awards are the first to be made.

The medal awarded to Professor Onnes was received on his behalf by His Excellency, Chevalier van Rapard, Minister from the Royal Netherlands Government, at the stated meeting of the Institute on the evening of Wednesday, May 19, and at this meeting Mr. Edison was the guest of the Institute and received his award in person. Following the presentations, an address entitled "Electricity and Modern Industrial Growth" was delivered by Mr. Insull.

ANNIVERSARY OF WORCESTER POLYTECHNIC INSTITUTE

The Fiftieth Anniversary celebration of the Worcester (Mass.) Polytechnic Institute will occur from June 6 to 10 in connection with the Commencement exercises, and the character of the celebration will be such as to make the event also a celebration of the achievements of engineering and science.

On Wednesday, June 9, there will be addresses by engineers of international reputation, following which there will be a special meeting of the Local Section of The American Society of Mechanical Engineers, and a banquet in the evening.

General George W. Goethals has accepted an invitation to be present and speak upon the part the civilian engineer has taken in America's outlying possessions, and it is hoped that President Wilson, who was the commencement orator twenty-five years ago and has expressed a desire to attend, may be able to be present. Addresses will also be made by Dr. John A. Brashear, President Lowell of Harvard and Governor Walsh of Massachusetts, and others of wide reputation.

BOILER CODE IN EFFECT IN OHIO

Those who have been interested in the work of the Boiler Code Committee and the development of the Code, the completion of which was announced in The Journal for March, will be interested to learn that it has been put into effect in the State of Ohio. At a meeting of the Ohio Board of Boiler Rules held on March 25, the Code was placed in force by the adoption of the following resolution:

Until further notice an inspector holding a certificate of competency and a commission authorizing him to inspect steam or hot water boilers which are to be installed within the State of Ohio, is hereby authorized to inspect during construction and on completion stamp Ohio STD with serial number any boiler constructed in accordance with the rules formulated by the Boiler Code Committee as submitted to the Council of the American Society of Mechanical Engineers on February 13, 1915.

(Signed) Ohio Board of Boiler Rules,
H. V. NEFF, Chairman.

The State of Ohio has had in force for some time a code of boiler rules which has been very satisfactory, and in consequence, this action is certainly a very strong endorsement of the A. S. M. E. Boiler Code. It should assist very greatly in securing the adoption of the A. S. M. E. Code in other states.

The Boiler Code has also been further endorsed by a meeting of representatives of the American Boiler Manufacturers' Association and of the National Tubular Boiler Association, held in Pittsburgh on March 29, where the report of the Boiler Code Committee was unanimously adopted and ways and means were discussed for promoting the adoption of the standard specifications by the various states. This meeting gives to the Boiler Code a tremendous impetus, as it puts back of it the endorsement of practically the entire boiler manufacturing industry. This marks the climax of a continuous effort for twenty-five years to get a standard specification that would be acceptable to engineers, manufacturers and users of boilers and boiler insurance companies, and these actions would indicate that the Code is in itself as nearly right from a mechanical and engineering standpoint as it is possible to construct such a code.

CLASSIFICATION OF TECHNICAL LITERATURE

Delegates from about twenty national technical and scientific societies met in the United Engineering Society Building, New York, on May 21, to perfect a permanent organization, the purpose being to prepare a classification of the literature of applied science which might be generally accepted and adopted by these and other organizations.

There was a generally expressed opinion that such a classification, if properly prepared, might well serve as a basis for the filing of clippings, for cards in a card index, and for printed indexes; and that the publishers

of technical periodicals might be induced to print against each important article the symbol of the appropriate class in this system, so that by clipping these articles a file might be easily made which would combine in one system these clippings, together with trade catalogues, maps, drawings, blue prints, photographs, pamphlets and letters classified by the same system.

By request, W. P. Cutter, the Librarian of the Engineering Societies' Library, and a delegate from the American Institute of Mining Engineers, read a paper on The Classification of Applied Science, in which, after describing the existing classification, of one of which he is the author, stated that, in his opinion, no one of these, although having excellent features, was complete and satisfactory enough to be worthy of general adoption. He outlined a plan whereby a central office could collate all the existing classifications, and, with the help of specialists in the various national societies interested, might compile a general system which would meet with general acceptance.

The name adopted for this organization is Joint Committee on Classification of Technical Literature, and the officers elected are: Chairman, Fred R. Low; Secretary, W. P. Cutter, 29 West 39th Street, New York; Executive Committee: the above, with Edgar Marburg, H. W. Peck, Samuel Sheldon.

SAN FRANCISCO MEETINGS

That there may be no misunderstanding in connection with the special train, New York to San Francisco, for the International Engineering Congress and the meeting of the Society in San Francisco in September, the Secretary wishes to announce that the special train under the direction of the committee of the joint engineering societies, is via Niagara Falls. The itinerary of this train is as follows:

Thursday, September 9:	
Leave New York (Grand Central Terminal).....	7:45 p. m.
Arrive Albany.....	11:10 p. m.
Leave Albany.....	11:15 p. m.
Friday, September 10:	
Arrive Niagara Falls, N. Y.....	7:30 a. m.
Leave Niagara Falls, N. Y.....	11:30 a. m.
Arrive Chicago, Ill.....	10:55 p. m.
Leave Chicago, Ill.....	11:55 p. m.
Sunday, September 12:	
Arrive Colorado Springs, Colo.....	7:30 a. m.
Leave Colorado Springs, Colo.....	7:00 p. m.
Monday, September 13:	
Arrive Albuquerque, N. Mex.....	12:15 p. m.
Leave Albuquerque, N. Mex.....	1:15 p. m.
Tuesday, September 14:	
Arrive Grand Canyon, Ariz.....	4:00 a. m.
Leave Grand Canyon, Ariz.....	7:00 p. m.
Wednesday, September 15:	
Arrive San Francisco, Cal.....	9:00 p. m.

GENERAL NOTES

An attractive student publication has come to the Secretary in the form of a souvenir number entitled an "Engineer's Special Issue" of the Round-Up, published at State College, New Mexico. This is an eight page paper filled with live matter relating to the col-

lege and student activities, but in this issue the bulk of the publication is devoted to the engineering courses and shows by extended articles and numerous half-tone illustrations the work and activities of the engineering school. The publication is unique in its advertising possibilities through its departure from the usual college bulletin.

The inauguration of Edward Kidder Graham as President of the University of North Carolina took place at Chapel Hill, N. C., April 21. He is the tenth president of the oldest state-supported university in the United States and is one of the youngest college presidents. The Society was represented at the inauguration exercises by Park A. Dallis of Atlanta, Ga., who was appointed Honorary Vice-President for the occasion. Among the delegates and visitors who formed the procession were the Governor and Justices of the Supreme Court of North Carolina, Secretary Daniels of the Navy, in addition to the past-presidents and faculty of the University.

Several complaints have come to this office of men who have posed as members of the Society and have attempted to borrow money on the strength of their membership. Three such cases have come to our attention and members are warned that they should be on their guard against such forms of imposition. A person thus representing himself should at least be able to show his membership card as evidence of sincerity.

APPLICATIONS FOR MEMBERSHIP

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i. e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of Grading are also posted. The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before July 10, 1915.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

ALEX, JESSE B., Ch. Engr. and Master Meeh., Tuttle & Bailey Mfg. Co., Brooklyn, N. Y.

- BUTLER, WILLIAM A., Asst. Supt. Pwr. Stas., Duquesne Light Co., Pittsburgh, Pa.
- BIGLOW, LEMUEL CAVALLI, Mgr., New York Office, Morse Chain Co. of Ithaca, New York, N. Y.
- BJORNSSON, CARL A., Desiging Engr., The McIntosh & Seymour Corp., Auburn, N. Y.
- CLARK, HAROLD H., Local Mgr., Link-Belt Co., Los Angeles, Cal.
- DAVISON, WOODFORD, Ch. Engr., Rancho La Brea Oil Co., Los Angeles, Cal.
- FLANNER, DOUGLASS D., Treas. and Genl. Mgr., Flanner Water Tube Boiler Co., Akron, Ohio.
- GOODWIN, E. CLAYTON, Supt., Hart & Cooley Co., New Britain, Conn.
- GREIST, HUBERT MILTON, Secy. and Supt., The Greist Mfg. Co., New Haven, Conn.
- GRIFFITH, LEIGH M., Mgr. and Co-Partner, Griffith Mch. Wks., Los Angeles, Cal.
- HALL, WINTHROP G., Asst. Supt., Spencer Wire Co., Worcester, Mass.
- HAYES, RALPH W. E., Mech. Engr., Hayes Pump & Planter Co., Galva, Ill.
- HICKS, GEORGE C., JR., Vice-Pres. and Engr., P. H. & F. M. Roots Co., Connersville, Ind.
- HOWE, JAMES F., Asst. to Dist. Mgr., American Steel & Wire Co., Worcester, Mass.
- JOHNSON, CHARLES L., Clerical Supt., Western Elec. Co., Hawthorne Sta., Chicago, Ill.
- KIDD, GEORGE F., Engrg. Dept., The New York Edison Co., New York.
- LANG, CHARLES W., Supt., Defiance Mfg. Co., Summerdale, Philadelphia, Pa.
- LAWTON, B. L., Treas. and Genl. Supt. of Factory, Conn. Tel. & Elec. Co., Meriden, Conn.
- LAWTON, CHARLES L., Genl. Mgr., Quincy Mine, Hancock, Mich.
- LITCHFIELD, H. L., formerly Elec. Engr., Choralcelo Co., Boston, Mass.
- LORD, ZENAS N., Dept. Foreman, General Elec. Co., Lynn Wks., West Lynn, Mass.
- MCGOWAN, HENRY E., Asst. Secy., The Brooklyn Union Gas Co., Brooklyn, N. Y.
- MAHM, ANEL C. V., Supt., The Egry Register Co., Dayton, O.
- MAXWELL, HOWARD, Engr., General Elec. Co., Schenectady, N. Y.
- MULLIN, JOHN T., Mech. Draftsman, Mead-Morrison Mfg. Co., Chicago, Ill.
- PARK, EDWIN HERVEY, Asst. to Master Mech., Wright Wire Co., Worcester, Mass.
- PERKINS, EDWIN A., Mech. Engr., The Norma Co. of America, New York.
- SCOTT, ROSSITER STOCKTON, Engr., Consolidated Gas, Elec. Light & Power Co., Baltimore, Md.
- THOMPSON, CHARLES F., Maintenance Engr., The Aultman & Taylor Mely. Co., Mansfield, O.
- TYLER, WARREN C., N. Y. Mgr., Poole Engrg. & Mch. Co., Woodberry, Baltimore, Md.
- WOLFF, JOHN, Mech. Engr., Cleveland Elec. Ill. Co., Cleveland, O.
- HETZEL, ROLAND F., formerly Ch. Designer, Puget Sound Mely. Depot, Seattle, Wash.
- LORD, HARRY C., Engr., with John A. Stevens, Cons. Engr., Lowell, Mass.
- REBEKE, ERNEST A., Ch. Draftsman, Mech. Div., Panama Canal, Balboa, C. Z.
- RUSSELL, WALTER W., Foreman, Jones & Lamson Mch. Co., Springfield, Vt.
- TILLSON, BENJAMIN F., Head of Min. Dept., New Jersey Zinc Co., Franklin Furnace, N. J.
- VAN WINKLE, HOWARD E., Territory Mgr., Overland Automobile Co., Manhattan, Kan.

FOR CONSIDERATION AS JUNIOR

- BARDROP, FRANK E., Asst. in Mech. Engrg., Rensselaer Poly. Inst., Troy, N. Y.
- BARR, KESTER, Special Rep., Lumen Bearing Co., Buffalo, N. Y.
- BISSELL, HARRIE G., Engr. and Draftsman, Munising Paper Co., Munising, Mich.
- BOSTWICK, W. WALKER, Spec. Apprentice for Engrg. Salesman, Ingersoll-Rand Co., Phillipsburg, N. J.
- BREED-LOVE, LINCOLN B., Instr., Robert College, Constantinople, Turkey.
- DAVIES, CLARENCE E., with Remington Typewriter Co., Syracuse, N. Y.
- HOWE, RALPH S., Engr. Mitchell Vance Factory, H. W. Johns-Manville Co., New York.
- HOWELL, KENNETH B., Engr., Barrett Mfg. Co., New York.
- KAPLAN, HARRY, Draftsman, Interborough Rapid Transit Co., New York.
- MILES, FRANK HAROLD, Foreman and Designer, The Milton Mfg. Co., Milton, Pa.

MODERN ELECTRIC ELEVATOR AND ELEVATOR PROBLEMS

BY DAVID LINDQUIST¹, NEW YORK

Non-Member

THE elevator art has gone through quite a number of more or less radical changes, particularly in the last fifteen years. These changes have been partly due to developments in building construction, utilizing steel as building material, thereby making it possible as well as practical to erect high structures. At the same time, it cannot be denied that the simultaneous development of commercial elevators particularly for high speed, has materially aided in the development of modern buildings.

Elevators may be classified according to the driving power employed: Steam driven elevators; Hydraulic elevators, and Electric elevators.

The first class, namely, steam elevators, is at the present time practically obsolete. There are, of course, quite a few of them still in existence and running, but there are no new plants of this type being installed at the present time.

Hydraulic elevators may be divided into several groups, depending upon the different methods in which the hydraulic power is transmitted to the elevator car. Some of the principal and well-known types are: The horizontal hydraulic (rope geared); the vertical hydraulic (rope geared), and the plunger hydraulic (direct connected). These types have been mentioned in the order they were introduced for high speed in comparatively high buildings. The plunger type practically superseded other types of hydraulic elevators during the period of 1904 to 1907, and in turn the plunger has now been almost entirely superseded by the gearless 1:1 traction type of electric elevator.

Without considering in detail the technical features of the plunger elevator in comparison with the gearless electric traction type, the principal reasons for this change in elevator practice may be summarized as follows:

- a Higher initial cost of a plunger installation.
- b Larger amount of total space in the building occupied by the machinery.
- c Lower car mileage and consequently more elevators required for the same service.

¹ Chief Engineer, Otis Elevator Company.

Presented at the New York local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on April 13, 1914.

The tall buildings of New York have been made possible by the development in elevators

d Higher power consumption.

The principal features of both the gearless and gear traction type of elevators will be described, the gearless, however, being treated more in detail.

Location of Machine. When considering the installation of the traction electric elevator the first question which arises is as to where the machine may most suitably be placed. There is no question but that placing the machine directly over the hatchway, as indicated in Figs. 2 and 3, is the most suitable arrangement. With this overhead location the best results are obtained, and the principal advantages may be enumerated as follows: better traction, less amount of rope, longer rope life, minimum space required, and higher efficiency.

It will be perfectly plain, if one stops to consider, that placing the machine directly over the hatchway will im-

pose less load on the building than if the same machine were placed below. Placing the machine directly above the hatchway imposes a load on the building equal to the weight of the hoisting machine plus the loads on car and counterweight ropes, whereas placing the machine below, imposes a load on the building equivalent to twice the loads on the car and counterweight ropes. For a duty of 2500 lb. at 700 ft. per min., the hoisting machine weighs about 16,000 lb., which is considerably less than the total load on car and counterweight ropes.

In the above example, the machine, due to high speed, is quite heavy in proportion to the load. A machine intended for lower speed would weigh still less and make the difference in loads imposed upon the building, to which attention is called, even more apparent.

Locating the machine above also takes up less space in the building than locating it elsewhere. It also somewhat prolongs the life of the ropes, as by this arrangement the rope is not subjected to so many bends. Placing the machine overhead also increases the overall efficiency of the installation.

Roping. The next consideration is that of roping. The roping of a so-called gearless 1:1 traction machine located overhead is extremely simple, as indicated in Fig. 4.

The principle of the traction drive is no doubt very old but its commercially successful application to an elevator

machine, consisting of a slow speed electric motor directly connected to the driving sheave, was first accomplished about ten years ago. Some attempts had previously been made, particularly by Dawelius, who built two, or possibly three, machines. For a number of reasons, however, they were not considered practical and he finally abandoned the attempt,

FIG. 2 ARRANGEMENT OF APPARATUS IN A TYPICAL GEARLESS TRACTION ELECTRIC ELEVATOR INSTALLATION

for apparently he could not produce a successful gearless electric elevator machine.

At first glance, it would appear as if the traction drive would be rather uncertain, when considering that the ropes are not actually latched to the driving member, that they simply go around the driving sheave of the motor, and depend solely upon the friction, or adhesion between the ropes and the driving sheave. This, however, is not the case; on the contrary, it is safer than any other method of drive.

Before any of these traction machines were put on the market, a large number of tests were made under such variable conditions as would be encountered in actual installations. It was found that with one-half wraps around

the driving sheave the maximum traction relation—that is, the relation between the load on the heavy side of the ropes to that on the light side—was 1.56, and the minimum traction relation, with one-half wraps was 1.4. With two half wraps as indicated by diagram, Fig. 4, the maximum relation is 2.43 and the minimum 1.96; the increase being of course in logarithmic proportion.

The maximum was obtained with a new turned sheave with practically new ropes and without any lubrication. The minimum was obtained with smoothly-worn sheave and ropes well lubricated, and with comparatively light tension and high speed. The principal reasons for this result are that with light tension and high speed there is an oil film between the rope and the sheave; moreover, the rope does not make contact fully 180 deg. with the sheave, due to the stiffness of the rope and centrifugal action.

The small variation, or the constancy of the traction is quite remarkable, and as long as the maximum variations in

FIG. 3 DETAIL VIEW OF THE OVERHEAD INSTALLATION OF A GEARLESS TRACTION ELECTRIC ELEVATOR

the load on a traction type elevator are such as not to require more than the minimum possible traction relation above mentioned, no slipping can occur.

Under ordinary conditions a 1:1 traction machine is usually provided with six ropes $\frac{5}{8}$ in. in diameter. The material is of soft steel, and in actual installations this will give a safety factor of not less than twelve.

Each rope is provided with a self-adjusting swivel rope hitch of the ball and socket type. This permits a gradual creeping and thus prevents any excessive twisting strain, and relieves the rope of the bending strains at the hitch, principally caused by vibration.

The traction method of drive has a number of inherent safety features. Traction elevators are arranged so that in case of overrun at terminals, either the car or counterweight bottoms on a buffer, thereby reducing the traction sufficiently to prevent further motion of the car and counter-

weight, even if the motor keeps on running. The car buffer is usually an oil buffer of a spring return type and mounted in the bottom of the pit, as illustrated in Fig. 5. As shown in Fig. 4, the counterweight buffer is mounted on the counterweight, and acts also as counterbalance. This latter buffer has gravity return, whereas the car buffer has spring return.

For very high rises, the great weight of the hoisting rope will cause considerable traction, even after the car or counterweight has landed on its buffer. This traction, together with the momentum of the car or counterweight, may cause either of them to travel into the overhead work, under conditions of runby clearance usually available. To prevent

about six or seven persons. Thus, with six or seven persons in the car, giving balanced condition, it is apparent there would be no *net load* to be lifted and the only power required would be for acceleration and for overcoming friction and electrical losses.

It is obvious that with a high rise elevator the variation in the net load on the elevator machine due to the shifting of the weight of the hoisting ropes from one side to the other of the driving sheave as the car moves up and down, would be excessive if this were not compensated for. This compensation is usually obtained by means of chains or ropes attached to the car and counterweight, and running down the

FIG. 4 DETAILS OF THE ROPING OF A TYPICAL GEARLESS LIFT TRACTION ELEVATOR

this, some of the exceedingly high rise buildings are equipped at the top of the hatchway with a retarding and latching device for both car and counterweight, in addition to the regular oil buffers acting in the pit. In case of abnormal overrun, the retarder brings either car or counterweight to rest and the latching device prevents subsequent downward movement.

Counterweight and Rope Compensation. The counterweight, the mechanical construction of which may be seen in Fig. 2, equals in total weight the weight of the car plus usually about 40 per cent of the maximum load. If we consider an elevator of 2500 lb. lifting capacity, 40 per cent of this equals 1000 lb. (the overbalance) and this represents

FIG. 5 DETAIL VIEW OF CAR BUFFER OF THE SPRING RETURN TYPE

latch in a loop. In Figs. 2 and 4 may be seen the compensating ropes running down from the bottom of the car to the tension sheave in the pit and up to the counterweight. The weight per foot of these compensating ropes is such that they, together with the electric cables (that lead to the car), will compensate the weight of the hoisting ropes regardless of the position of the car.

For all high speed high rise elevators, compensating ropes are used. In the pit a tension device is provided for the compensating ropes. For moderate rises and comparatively slow speeds, chains may be used instead of ropes.

Driving Motor. The electric motor is of the slow speed type, generally six pole and usually provided with shunt field only. The armature is series-wound with conductors of rectangular cross section, in order to get the maximum amount of copper in the armature. With a 36 in. driving sheave, a car speed of 600 ft. per min. corresponds to 63.6 r.p.m. of the motor. Figs. 6 to 9 show the compact design of the motor, and Figs. 8 and 9 show machines provided with ball bearings, which it may be seen are shorter than the regular babbitted bearings. The principal features of the motor with driving sheave, commutator, electro-mechanical brake, brake shoes, etc., are clearly illustrated.

Up to even a comparatively late date, it seems to have been the general impression that a motor of moderate duty, having a speed so exceedingly low as that required for this

gearless type of elevator, would have also a low efficiency; but this is not the case. On the contrary, it has been demonstrated, and proven a number of times, that a motor with this low speed can be designed to have just as high efficiency as any high speed motor of equal output. One peculiar feature about the efficiency of this motor is that it is unusually high at light loads. This is particularly of advantage in connection with elevators where the average load on the motor is usually less than one-half its rating.

The curve in Fig. 10 shows the result of a test on a traction motor installed in the Metropolitan Life Tower. This motor was rated at 38 h.p., at which full load capacity an efficiency of 89 per cent may be observed. At half load, the motor shows an efficiency of 91.5 per cent and at quarter load

FIG. 6 A TRACTION ELECTRIC ELEVATOR MACHINE OF THE 1:1 TYPE

over 90 per cent. It may be said that these are uncommonly high efficiencies for a motor of 38 h.p. capacity, designed for a speed of 58 r.p.m. at 110 volts.

The curve in Fig. 11 shows the result of a test of a traction motor installed at the 181st St. Subway Station in N. Y. City. This curve shows that the motor has a maximum efficiency of 93 per cent at about half output and illustrates still better the remarkable results that can be obtained with motors of abnormally slow speed for comparatively small outputs. These efficiencies are, as a matter of fact, considerably higher than is usually obtained in high speed motors of corresponding horse power; particularly is this true with light loads. Further reference to motor efficiency will be made in connection with power consumption.

The driving sheave is commonly about 36 in. in diameter, and the driving sheave and brake wheel are of the rim type, cast integral and bolted to the armature sleeve or spider. Circular rope grooves are employed. The brake is of the shoe type, and the magnet is usually provided with series-winding for quick release, and with a shunt-winding for holding. The brake shoes are provided with a lining of fabricated asbestos. A gradual and soft application of the brake is obtained by a particular method of magnetic retardation of the magnet cores, eliminating thereby the necessity for dash pots. The brake shoes were formerly, for some

time, lined with leather, but after very exhaustive tests of a number of different brake lining materials, it was found that a certain kind of fabricated asbestos was the most suitable. The particular qualities or characteristics of this brake lining are, that the friction between the lining and the wheel is practically constant at all times. Tests have been made and the temperature ran up to about 400 deg. cent., but there was no appreciable variation in the friction. Furthermore, the coefficient of friction is very constant, varying but little with variations in speed. The variation is remarkably small as compared with leather. With leather, it was frequently noticed that the machine would come almost to a stop, and then creep, just as in the case of a hydraulic elevator with a slight leakage of water. This was due to the fact that the friction coefficient between the leather and the brake wheel was very much lower at slow speed than at high, the minimum being obtained at practically zero speed.

Bearings. The bearings are either of the ordinary babbitt lined, self-aligning type, with automatic chain-oiling, or are of the anti-friction type (ball or roller bearings). Elevators of the gearless traction type have been for some time equipped with ball or roller bearings, which are used for both the main motor, and rope sheave bearings. They were

FIG. 7 A TRACTION ELECTRIC ELEVATOR MACHINE OF THE 2:1 TYPE

adopted primarily to gain space, and it is readily apparent that these anti-friction bearings take up much less room than the plain solid bearings. It followed therefore that a traction machine equipped with them could be designed to take up less space, and thus, in many instances, eliminate the necessity for double decking an installation consisting of a number of adjacent elevator machines; by "double decking" is meant the placing of machines on two levels, when the machine is longer than the center distance between adjacent hatchways, thus preventing their installation on one level.

In the case of elevators with 2:1 roping, this saving in space in connection with the sheaves, really becomes a neces-

sity; for here, particularly in the counterweight sheave where space conditions are always limited, a plain babbitted bearing of suitable capacity would be practically impossible. Of course, the use of these anti-friction bearings also introduces other very decided advantages,—materially reducing friction, particularly at starting, and introducing a smoothness of operation superior to plain bearings. This is again particularly applicable to the sheaves used with machines having 2:1 roping, for here the additional number of sheaves requires that the friction be reduced to a minimum.

As to the relative merits of ball or roller bearings, opinions differ greatly. Personally, I consider ball bearings, at the present time, superior to roller bearings for electric elevator machines. My reasons for this are based upon considerable investigation which has convinced me that ball bearings can be successfully and practically produced of sufficient capacity to withstand the service imposed. Further than this, ball bearings possess the inherent advantage of being able to run slightly out of alignment without causing destructive strains or excessive friction. With roller bearings slightly out of alignment, even though this be not sufficient to set up destructive strains, the friction will be increased very materially. As a matter of fact, actual tests

At the start, the ball bearing manufacturers apparently and unfortunately did not fully appreciate the special features of design that were required, with the result that some of the earlier bearings of this type were not as suitable as they might have been, or are to-day. However, even taking this fact into consideration, there have been, in proportion to the large number used, very few that have proved unequal to the duty imposed upon them. It is pleasing here to record that while at the start it was supposed that the foreign-made ball bearing represented the highest state of development, to-day the American product has proved itself by far the best that can be obtained.

The total losses in ball bearings may be considered due to three distinct causes; namely, rolling friction, sliding friction

FIG. 8 A TRACTION MACHINE OF THE 1:1 TYPE FITTED WITH BALL BEARINGS

have shown that friction induced in this manner can readily be in excess of the friction in a plain bearing. Furthermore, ball bearings are capable of resisting a certain amount of end thrust; quite sufficient, in the case of these traction machines, to take care of the "float" of the armature, partly due to magnetic action, and added to by the action of the hoisting ropes. Roller bearings will permit of no end thrust at all, and therefore when they are used, additional means must be provided to take care of this.

The introduction of ball bearings in connection with elevator machinery was something of an innovation, and entailed the use of bearings of considerable size and strength.

FIG. 9 A SAFE-LIFT TRACTION MACHINE FITTED WITH BALL BEARINGS

and losses caused by the lubricant. The rolling friction is that loss due to the slight deformation of the balls and their races; this loss is exceedingly small. The sliding friction occurs between the balls and their cage, and to a slight extent between the balls and the races; this latter is occasioned by the differing velocities at various points of contact between the balls and the races, due to deformation. The sliding friction between the balls and their cage in a radial type of bearing is also very small, and consideration of the sliding friction between balls and races may usually be neglected unless the difference in velocities is considerable, as may be the case in the use of ball bearings with close fitting races, heavily loaded.

Paradoxical though in sound, it should be noted that the principal loss in ball bearings is that caused by the use of a lubricant. This loss, of course, depends upon the viscosity of the lubricant and increases greatly with the speed. It is due partly to the churning of the lubricant and partly to the force necessary to squeeze it out of the path of the balls. The main reason for its use is for protecting the bearings from corrosion. The best protection for slow speed bearings is obtained by the use of a moderately heavy grease which

FIG. 10 EFFICIENCY TEST OF A TRACTION MOTOR IN THE METROPOLITAN LIFE TOWER

FIG. 11 EFFICIENCY TEST OF A TRACTION MOTOR AT THE 181ST ST. SUBWAY STATION, NEW YORK

FIG. 12 TYPICAL OVERHEAD INSTALLATION OF TRACTION ELECTRIC ELEVATOR MACHINES WITH PLAIN BABBITTED BEARINGS

will not flow. Protection from corrosion is important since a speck of rust may soon ruin a bearing. The lubricating properties also reduce wear.

Method of Control. Figs. 14 and 15 show controllers used in connection with 1:1 and 2:1 traction elevators and Fig. 16, an installation of a large group of controllers. The speed variation necessary in connection with high speed traction elevators is obtained, partly by field regulation and partly by series and by-pass resistance in the armature circuit. The field regulation is usually capable of reducing full speed down to a speed from 60 to 40 per cent of full speed; further slow-down is obtained by resistance control.

The combination of the two methods mentioned is necessary for obtaining sufficiently slow car speed (about 90 ft. per min.). This slow speed is required for making accurate stops both at intermediate and terminal landings, and also in order to make a very short travel, or to "inch" up or

down, to the landing. The exceedingly slow speed automatically obtained when approaching terminal landings is necessary not only to secure accuracy of stops with varying loads, but to provide a fundamental safety feature. It may be mentioned that anti-friction bearings not only materially aid in obtaining smoothness of operation but greatly facilitate the "inching" up to the floor landings.

As a matter of fact, the 1:1 electric traction machine with ball bearings, has practically the smoothness of motion when running, starting and stopping, so much appreciated in hydraulic elevators; yet it comes to a positive stop without the objectionable oscillation and subsequent creeping, inherent in hydraulic elevators.

In connection with the regular operating features of the control apparatus, there are also a number of other features introduced for the purpose of safety. Some of these may be merely mentioned without going into too great detail:

- a Automatic return of car switch to "off" position.
- b Automatic stopping switch on car for automatic stopping at terminal landings.
- c Final cut-out limit switches in hatchway operating independently of the automatic stopping switch.
- d Switches operated by centrifugal governor automatically stopping the elevator in case of overspeed; the first switch cuts the power off from the machine and applies the dynamic brake effect to the armature, and applies the mechanical brake to the brake pulley; the second switch applies the light retarding force to the car safety referred to later under the subject of electro-mechanical safety.
- e The safety switch in the car under the control of the operator also performs the same function as the two switches operated by the governor.
- f Regulation of shunt field by centrifugal governor to maintain constant full speed with variable loads.

FIG. 13 AN INSTALLATION OF BALL-BEARING TRACTION MACHINES

- g Oil buffers as previously mentioned, capable of independently stopping the fully loaded car when descending at 50 per cent excess speed without discomfort to the passengers.
- h For high rise elevators the use of a mechanical retarding and latching device.

Fig. 17 shows the switch located on the car to effect the automatic stop at terminal landings. This switch is provided with a lever actuated by two cams in the hatchway, one at the upper landing and one at the lower.

Loads and Speeds.—Gearless traction machines, utilizing 1:1 or 2:1 roping, have been built for loads varying from 2000 lb. up to 11,000 lb. at car speeds from 350 up to 700 ft. per min. Of these duties the most generally used for the modern high office building, utilizing 1:1 roping, is about 2500 lb. at a speed of 600 or 700 ft. per min., although in many instances, a speed of 500 to 550 ft. per min. is found suitable.

The speed of the high rise elevators in the Woolworth Building is 700 ft. per min., which is at present the highest elevator speed permissible in New York City. In the new Equitable Building in New York, certain of the elevators are arranged to run a portion of their travel on express service

at a speed of 650 ft. per min. and the rest of their travel on local service at 550 ft. per min. The change in car speed is automatically accomplished at the point in the hatchway where the character of the service changes. The point at which this change in speed occurs can readily be altered at any time to suit the requirements of the building. The owners of this building considered that a change in speed as just described would be advantageous, and no doubt this will prove to be the case. Reference to the curves in Fig. 18 will make the fact apparent that a reduction in speed from that of the express run, is desirable when the elevator is running

FIGS. 14-15 TYPICAL CONTROLLERS USED WITH TRACTION ELECTRIC ELEVATOR MACHINES

in local service. The advantage is found in a reduction of power consumption without an appreciable loss of service time.

The curves in Fig. 18 were produced from tests of the elevators installed in the Metropolitan Life Tower. They show the relation between time and speed, both for express runs and for stopping at every floor; ascending and descending with full load. It will be noted that the maximum speed attained when stopping at every floor is only about 70 per cent of the full speed attained during express run. This is, however, a rather extreme case as the car was very heavy, the ropes were long and consequently the masses to be accelerated were unusually great.

For more moderate speeds and heavier loads, a 2:1 roping of car and counterweight is utilized (shown diagrammatically in Fig. 19), which retains the safety features and general characteristics of the 1:1 equipments. For moderately high

buildings, this 2:1 roping is suitable for a car speed not in excess of 450 ft. per min.

Geared Machines. The traction principle is also applicable to elevator machines employing moderately high speed motors with some form of gearing between the motor and driving sheave. Machines of the geared type are most suitable when lower speeds are involved or where the service con-

ditions are not so severe. Under these conditions the power consumed will be comparatively small on account of the lesser mileage, and hence the more expensive gearless machine with its reduced power consumption may not be necessary.

Two types of geared machines have been developed, one employing worm gear and the other herring-bone gear reduction (see Figs. 20 and 21). Of these two, the worm geared is suitable for slow and more moderate speeds, and is used extensively for this purpose. The machine with herring-bone gear reduction is of course not suitable for slow car speeds on account of the difficulty in obtaining sufficient speed re-

FIG. 16 A LARGE GROUP OF TRACTION ELEVATOR MACHINE CONTROLLERS IN AN OVERHEAD INSTALLATION

As far as smoothness of operation is concerned, a geared machine can obviously never equal that of a gearless, on account of the fact that it is practically an impossibility to manufacture any kind of gears which are perfect, and mount the same in absolute alignment. Furthermore, if this condition of perfection could be established, it could not be maintained in service, on account of the inevitable wear that would take place.

Undoubtedly, it is somewhat more efficient than worm gearing, and has been used with some success in connection with quite high speed elevators. The fact that the herring-bone geared machine has been used for these high speeds should not be understood as indicating that it is equal to the gearless machine, with which it cannot compare as to operating features and power consumption.

Of the two kinds of gears mentioned, the worm gear has inherently less tendency to vibrate than the herring-bone gear. On the other hand, the herring-bone gear is generally more efficient than the worm gear.

FIG. 17 AUTOMATIC STOPPING SWITCH LOCATED ON CAR

FIG. 18 SPEED CURVE OF HIGH-RISE ELEVATOR IN THE METROPOLITAN LIFE BUILDING TOWER

A number of tests of herring-bone gears (Fig. 22) cut by Falk, Fawcett and Otis, have been made, and Fig. 23 shows the results of a series of tests of one particular gear. The difference in efficiency at various speeds is noticeable. This gear has 213 teeth and the pinion 23 teeth, resulting in a gear ratio of 9.27:1. A motor speed of 425 r.p.m. gave a car speed of 500 ft. per min. There was quite a difference in the efficiency of the gear at different speeds. The losses included in figuring the efficiency comprised the bearing losses and losses due to the churning of the oil. The difference in the efficiencies at different speeds is due principally to this churning of the oil, the loss from this source being about 1.5 h.p. at a speed corresponding to a car speed of 500 ft. per min. This appears to be quite a considerable loss, when considering that it is a loss due to the lubricant.

FIG. 19 2:1 ROPING OF A GEARLESS TRACTION ELEVATOR

If the oil is taken out of the gear case and an amount of oil sprayed on sufficient only to prevent cutting, these efficiencies are somewhat increased, particularly for high speed. Under these conditions, the efficiency is practically the same at different speeds; in other words, the efficiency goes quite a little over 90 per cent.

A great number of tests were made also of worm gears with from 1 up to 12 threads on the worm, and with a large variation in the number of teeth in the worm gears. With a 12-thread worm and a 108 tooth worm gear, giving a speed

reduction of 9:1 or about the same as that of the herring-bone gear, the efficiency was only from 2 to 3 per cent lower, indicating that for high speeds, with comparatively low ratio of reduction, the worm gear is quite efficient. The worm gears with high pitch worms are by no means as inefficient

FIG. 20 A GEARED TRACTION ELECTRIC MACHINE USING WORM GEARING

FIG. 21 A GEARED TRACTION ELECTRIC MACHINE WITH HERRING-BONE GEARING

as generally thought. The effect of the oil in this case was practically the same as already mentioned in connection with the herring-bone gear; in other words, at a speed corresponding to 500 ft. per min. car speed, the oil losses were about 1.5 h.p.

Power Consumption. Considerations of power consumption in the machine may be divided into three parts relating respectively to motor efficiency, gear efficiency and inertia:

First. The maximum efficiency of the high speed motor used in connection with the geared machine may occasionally be as high as that of motors used with the gearless, but the efficiency at lighter loads, which is the normal service condition, is lower; hence the high speed motor is at a disadvantage. An equal amount of field regulation may be applied to both high and low speed types of motors.

Second. High speed motor machines may be considered to have, under the best conditions, a gear loss of about 10 per cent, whereas this loss is entirely eliminated in the gearless machine.

Third. Although kinetic energy is the most important factor in power consumption, it has in the past been apparently very little considered. The reason for this is due probably to difficulty in readily determining its amount, in a rather complex elevator machine. A method which is very simple and at the same time quite accurate, will therefore be described.

One of the methods for determining the kinetic energy consists in determining the amount of the inertia of the rotating parts of the elevator by, for instance, the pendulum method, and in ascertaining the mass of the other parts, having straight line motion, by weighing them. This method has a disadvantage in that it cannot be applied to a complete elevator installation. In addition, it is difficult and tedious of execution.

A simpler and more accurate method, not affected by the

FIG. 22 HERRING-BONE GEAR AND PINION

variation of the coefficient of friction and the windage losses at different speeds, may be explained as follows:

The kinetic energy of a complete elevator system is the sum of the kinetic energies of each of its constituent parts. In general, these parts run at different speeds, but by reducing all forces and masses to a certain speed, say the speed of the elevator car, the problem can be treated as if involving a single body. If the speed in feet per second of this body equals v_1 when the time equals zero, the kinetic energy ($E = 1/2 m v_1^2$) may be expressed by the equation:

$$E = \int_0^T p v dt$$

in which v = the speed at the end of t seconds, p = the retarding force in pounds at the time t , and T = the time in seconds in which the body comes to rest. In this equation $p v$ is the work in foot pounds per second done by the retarding force.

If the rate of work is expressed in watts, we have

$$E = 0.7373 \int_0^T w dt$$

in which w represents the retarding watts at the speed v . It will be noted that the quantity under the integral sign is the area comprised between the retarding watt-time curve and the axis of time.

To obtain the data for this curve, we may assume the object to be the determination of the kinetic energy of a complete elevator installation at the time when the elevator car has attained the speed v_1 . Preferably, the load on the car side of the driving sheave should equal and balance that on the counterweight side. This can be accurately effected, without weighing, by merely taking watt-meter readings for up and down travel at equal speeds, adjusting the load in the car until the up and down readings are equal, indicating that both sides are balanced.

The car is then run at the speed v , when the armature current (but not the field current) is interrupted, so that the system may come to rest retarded by the mechanical friction, windage and core losses of the motor. The indicated work in watts due to friction, windage and core losses is then equal to the retarding watts w in the above equation. The speed and time are also observed and a graph of the speed-time curve is drawn.

Next, the motor is connected to the line, the elevator run at different speeds, and the watts input observed for each speed. If the I^2R losses represent the losses in the armature winding of a direct current motor and W , the observed watts

FIG. 23 RESULTS OF EFFICIENCY TEST OF A HERRING-BONE GEAR

required to run the elevator at the speed v , evidently then $W - I^2R$ gives the watts necessary to overcome the friction, windage and core losses. Consequently, $W - I^2R$ at the speed v , is equal to the retarding watts w at that speed.

The second series of observations, therefore, provide the data for the graph of the retarding watts-speed curve. Having thus obtained the graphs of the speed-time curve and of the retarding watt-speed curve, it is a simple matter to construct the retarding watt-time curve. The quantity W may then be obtained by means of a planimeter and, with the aid of the above equation, the kinetic energy at speed v_1 may readily be calculated.

The retarding watt-time curve is so nearly a parabola that only an inappreciable error results from considering the curve as such. Instead of obtaining the area representing $w dt$ by means of a planimeter, it is sufficient to employ the equation of a parabola, whereby this area is found to be one-third of the product $w_1 T$; w being equal to w_1 when the speed $v = v_1$ which occurs when $t = 0$.

When, therefore, extreme accuracy in the determination of the kinetic energy is not required, it is sufficient to obtain merely two observations or readings; one being the time T in seconds in which the elevator comes to rest after the armature current is interrupted at the speed v_1 , and the second

being w_i in watts, which is equal to the watt-input W required to run the elevator at the speed v_i minus the FR losses.

If it is required to determine the kinetic energy of the hoisting machine only, the car and counterweight may be blocked, and the tests made as before. By removing from the machine part after part, and making tests after each removal, the kinetic energy of each of the various moving parts may be obtained.

It will be noted that the method outlined above refers to direct current machines; however, with necessary modifica-

tion power is lost in the starting resistance and some in the motor. The loss in the starting resistance and motor is certainly larger than the energy recovered at the stop, and hence the cost per year for accelerating and retarding 219 lb. of weight, under the above conditions, would amount to more than \$273.00.

In ordinary passenger service the load taken up and distributed to the various floors of the building is practically the same as the load brought down to the starting point, therefore, the electric power consumed is not primarily power required for the transportation of passengers, but is

FIG. 24 POWER CONSUMPTION CURVES OF A TRACTION ELEVATOR MACHINE IN THE METROPOLITAN LIFE BUILDING TOWER

FIG. 25 EFFICIENCY OF COMPLETE GEARLESS TRACTION ELEVATOR INSTALLATION—NEW YORK TELEPHONE BUILDING

tions in regard to the determination of w , the retarding watts, this method may be applied to alternating current machines also.

An idea of the relatively high cost of operation of electric elevators, utilizing high speed motors with gears, may be gained by means of the following example: Assume a weight of 1 lb. revolving at a radius of 9 in. at 800 r.p.m. (which is the speed usual with motors for worm gear machines). The kinetic energy to be imparted to this weight each time it is started from rest and brought to full speed will then be 61.3 ft.-lb.

If the elevator starts on an average of 4500 times per day and runs three hundred days per year, the cost of the energy absorbed for acceleration, at 4 cents per kw.-hr. would amount to \$1.25 per lb. per year. If, instead of one lb., the weight were 219 lb. (which is the effective equivalent weight of a particular herring-bone gear machine), the cost would be \$273.00 per year.

Of course, part of the kinetic energy required for starting is returned at the time of stopping, but on the other hand the starting efficiency is low, since a large amount of the

FIG. 26 EFFICIENCY OF COMPLETE HERRING-BONE GEAR TRACTION ELEVATOR INSTALLATION—YALE CLUB BUILDING

work required to overcome friction and to supply the kinetic energy for each start, less the amount that is recovered at the stop. The friction losses are by far the smaller of the two. Therefore, a comparison of the kinetic energies of two elevators, for the same service and with the same method of control, gives a good indication of what their relative power consumption and rapidity of acceleration will be in actual service.

In the following tabulation are given the kinetic energies of two traction machines, one with herring-bone gear and the other gearless, both built for a car speed of 600 ft. per min., and for the same load. The herring-bone gear machine had a motor running at 505 r.p.m., a pinion with 23 teeth, gear with 215 teeth, and driving sleeve 42 in. in diameter. The gearless machine had a motor running at 63.6 r.p.m. and a 36 in. driving sheave.

		Kinetic energy in ft.-lb.	
Herring-bone gear machine	motor armature.....	7,420	
	brake pulley.....	2,920	
	driving sheave.....	1,000	
	herring-bone gear.....	2,060	
Total		13,400	
Gearless machine	Armature	Total	2,450
	brake pulley		
	driving sheave		

It will be noted that the kinetic energy per start of the herring-bone machine would be about 5.5 times that of the 1:1 gearless machine. Consequently, if the cost of power for accelerating and retarding the 13,400 ft.-lb. of the former amounted to \$273.00 per year, the cost for the gearless machine would be but $\frac{\$273}{5.5}$ or \$50.00.

It may not be at once apparent why the high speed motor with armature of much smaller dimensions, although running

FIG. 27. POWER CONSUMPTION TEST OF A TRACTION ELEVATOR MACHINE IN THE ADAMS EXPRESS CO. BUILDING

at high speed, should have such high kinetic energy, compared with that of a slow speed armature of much heavier weight and larger dimensions. A simple example may be given illustrating this fact.

Take a motor of certain construction and field strength, and assume that on a 220 volt circuit it will develop 10 h.p. and run at 100 r.p.m. On a 440 volt circuit, this same motor with equal armature current and with shunt field arranged to maintain the same field strength, will develop 20 h.p. and run at 200 r.p.m. That is, the voltage being doubled, the horsepower and speed will be doubled; and, the kinetic energy, varying as the square of the speed, will be quadrupled. If then, we assume the kinetic energy in the

first case to be 500 ft.-lb. that in the latter case will be 2000 ft.-lb., and the kinetic energy per horsepower of the motor running at 100 r.p.m. will be $\frac{500}{10}$ or 50 ft.-lb., and

that of the motor running at 200 r.p.m. will be $\frac{2000}{20}$ or 100 ft.-lb. In other words, in this example, doubling the speed will double the kinetic energy per horsepower output.

As already indicated, the kinetic energy of a complete herring-bone gear machine was approximately 5.5 times the kinetic energy of the gearless. This increase is not directly proportional to the speeds of their respective motors because the ratio between the kinetic energies of the driving sheave, brake and gear coupled to the motors, is considerably less than proportionate to the motor speeds. If, however, the

FIG. 28. AVERAGE POWER CONSUMPTION FOR VARIOUS LOADS AND NUMBERS OF STARTS—EXPRESS SERVICE—ADAMS EXPRESS BUILDING

FIG. 29. AVERAGE POWER CONSUMPTION FOR VARIOUS LOADS AND NUMBERS OF STARTS—LOCAL SERVICE—ADAMS EXPRESS BUILDING

armatures only are considered, the fact would be disclosed that in this case the kinetic energy is more than proportional to the speed because, on account of the gear losses, the geared machine requires a motor of greater capacity than does the gearless machine.

At this point, it may be interesting to observe the efficiencies and power consumption of some actual installations. The curves in Fig. 24 show recording wattmeter readings taken in the Metropolitan Life Tower of an elevator carrying a load of 2500 lb. up and down. The upper curve indicates the watts taken when lifting the load and the lower curve the watts required for starting, and the watts generated back into the line, when the load is descending.

The curve in Fig. 25 shows the efficiency of a complete installation of a gearless traction elevator in the New York Telephone building, at Walker and Lispenard Sts., New York. It may be noted that the maximum efficiency from line to load, allowing for all losses, is over 71 per cent. The curve in Fig. 26 shows the efficiency of a complete elevator installation of a herring-bone gear machine in the new Yale Club building in New York City. It may be noted that the maximum efficiency from line to load is about 62 per cent.

The curves in Fig. 27 show the results of recording watt-meter readings taken at the Adams Express Company's building, New York City. The loads indicated are net loads; that is, loads representing the unbalanced difference between weights on the car side and weights on the counterweight side of the driving sheave; and the ordinate at zero indicates the balanced condition of these weights. The broken curves, ascending from left to right, represent power consumption while lifting unbalanced weights. The broken curves, descending from left to right, represent power consumption

while lowering unbalanced weights. The full line curves, drawn between the former, represent the average power consumption required for lifting and lowering weights. Curves are shown for various numbers of stops per car mile, ranging from no stops to 402.

FIG. 33 LOCAL SERVICE

FIG. 30 EXPRESS SERVICE

FIG. 34 EXPRESS SERVICE

FIG. 31 LOCAL SERVICE

FIG. 35 LOCAL SERVICE

FIG. 32 EXPRESS SERVICE

FIG. 36 EXPRESS SERVICE

The average amounts of power consumption, for various loads and numbers of starts, are plotted in curves shown in Figs. 28 and 29. These curves indicate the increase in power consumption occasioned by an increase in number of starts while transporting various loads, Fig. 28 representing express and Fig. 29 local service. By referring to curve 2 in Fig. 28, it may be noted, that with a net or unbalanced load on the car side of the driving sheave of 500 lb., the power consumption would be 0.8 kw. per car mile when no stops whatever are made, and about 3.2 kw. when there are 100 stops. The net load of 500 lb. represents a load in car amounting to 1500 lb. partly balanced by a 1000 lb. counterweight. By comparing the curves one with another, it may be noted that the power consumption increases with the number of starts to a greater extent than with a corresponding increase in net load. Comparison between curves in Figs. 28 and 29 will indicate that the power consumption for equal

short periods of time, morning, noon and evening; as well as the normal traffic between times.

The curves in Fig. 36 illustrate the most severe "rush-hour" service encountered. It may be observed that at about 8.30 in the morning, there is a tremendous inrush for about twenty minutes, which tapers off to a slight rush later on; around ten o'clock, or half-way between the rush hours, there is about the same amount of service in both directions. Then just at twelve o'clock, sharp, there is a tremendous rush outward, which is all over in ten minutes. In other words, all these passengers have had to be taken out of the building in ten minutes, the same number being handled, from 12.20 on, during the inrush which, however, lasts for about twenty minutes. Then, during the afternoon, may be noted the continuation of traffic up and down, in about equal amounts. The promptness with which the people leave the building at night may be observed by referring to the curve in Fig. 36.

These charts show service conditions, indicating what tremendous variations of traffic are encountered in elevator service. In order to prevent congestion in a building the elevators must be capable of taking care of at least half, or say about two-thirds, of all the people in a building during practically only ten minutes. They indicate further how necessary it is to be able to maintain high speeds during rush hours. At such times, when the elevators have to carry all the people up, speed is an important factor. In this respect, the electric traction elevator has the advantage over the hydraulic elevator, in that it is capable of maintaining constant speed independently of the load, whereas the hydraulic elevator varies its speed with variations in load. In other words, during the time of maximum service, with fully loaded car, the hydraulic elevator runs at its minimum speed, whereas with light loads, when speed is not important, the speed is maximum. Undoubtedly, this indicates one of the principal reasons why the electric has gradually, and now almost entirely, supplanted the hydraulic elevator.

Electro-Mechanical Elevator Safety. In conclusion, mention may be made of various elevator car safeties, with particular reference to a new safety that has lately been put on the market. The essential requirement of an elevator car safety is to stop and hold an elevator car under all conditions of load and speed, whether the hoisting ropes are intact or parted. Fig. 37 illustrates the safety device usually employed until a comparatively short time ago; and which, even at the present time, is still installed. It is the standard so-called wedge clamp safety, which clamps the rails for retarding and holding the elevator car in case of overspeed or free fall.

The present practice utilizes the same principle of application whether the safety is actuated under conditions of excessive speed with hoisting ropes intact or during free falling. A very strong retarding force is required to stop a free falling car, but this strong retarding force if applied with ropes intact is excessive and will give an unpleasant shock to the passengers.

This is obvious when an actual installation is analyzed. The car, with all attachments, of a modern high rise elevator, weighs about 6500 lb., the maximum load is usually 3000 lb. and the compensating ropes weigh about 2500 lb.; the total load to be stopped by the safety with the ropes parted would therefore be 12,000 lb. To insure the stopping of a car, at

FIG. 37 A TYPICAL APPLICATION OF THE WEDGE-CLAMP SAFETY

loads and number of starts, is greater for the express service than for the local service, due to higher speed and greater masses.

A number of observations have been made of the actual service conditions encountered in different buildings. Some of the most interesting are those of the Hudson Terminal Building in New York City, where the service conditions are usually severe and varied. The curves in Figs. 30 to 33 record these conditions, indicating the number of cars in service, the power consumption in kilowatt hours, the miles traveled, the number of cars leaving the ground floor, the number of stops, etc., during hours from 8 a.m. to nearly 6 p.m. Both express and local service for certain groups of elevators at the 30 Church St. and the 50 Church St. buildings are represented.

The curves in Figs. 34 to 36 record the movement of passengers during different hours of the day; the upper curves showing the number of passengers carried up and the lower curves, the number carried down. These curves well illustrate the tremendous inrush and exodus of passengers during

least 50 per cent excess force should be provided, bringing the total retarding force required, up to a minimum of 18,000 lb. Were a major portion of this retarding force applied with the ropes intact, the car would be stopped too abruptly. This would be accentuated with a light load, particularly as the machine brake and strong dynamic action of the motor assist the retarding force of the safety.

For the above mentioned reasons, it is essential, therefore, that the safety should apply a *strong retarding* force in case of a free falling car with ropes parted, and a *light retarding* force in case of overspeed with ropes intact. The principal safety features which should be incorporated in an elevator safety for high speed elevators are as follows:

- a The safety should be so arranged that the application of a predetermined and definite *light retarding* force will stop the car and net load without shock in case of overspeed with hoisting ropes intact.
- b The safety device should be so arranged that the application of a predetermined and definite *strong retarding* force will gradually bring the car and maximum load to rest in case of a free falling car.
- c The *light retarding* force should be immediately applied, preferably by means of a centrifugal governor, in case the car should attain excessive speed in either direction.
- d It should be possible to apply immediately the *light retarding* force from within the car, when desired.
- e The *light retarding* force should be applied automatically in case of overrun at the upper or lower terminals, and yet be so arranged as not to interfere with the starting of the car in the opposite direction.
- f The *strong retarding* force should start to apply the instant the hoisting ropes part, independently of the speed of car and counterweight.
- g A tripping governor should not be necessary to apply the *strong retarding* force, except on safe lift machines.
- h In the case of safelift machines, a *strong retarding* force should be automatically applied independently of the parting of the hoisting ropes, at a definite speed which should be higher than the speed at which the *light retarding* force is applied.
- i The releasing carrier, even when improperly adjusted, should not prevent the application of a *strong retarding* force to the car in case the ropes part.
- j The principal actuating parts of the safety should be made to move automatically at frequent intervals, in order to prevent them from clogging up or corroding together; this motion of the actuating parts need be only very small, to give the desired results, but some motion is necessary to secure dependable action of the safety.

Figs. 38 and 39 show the general features of an electro-mechanical elevator car safety which embodies all of the above described requirements. The *light retarding* force is obtained by means of a helical steel spring forcing the wedges between the rollers of the safety jaws. When the car is in service this spring is held under compression by means of an electro-magnet. The instant the current in this magnet is interrupted, either by the centrifugal governor, safety switch in car or limit switches in the hatchway operated by the car or counterweight, the *light retarding* force is applied.

The *strong retarding* force is obtained by revolving the safety drum, thereby actuating the right and left hand screw, which in turn moves the wedges and forces the jaws against the guide rails. The *strong retarding* force is definitely de-

termined by the number of turns around the safety drum, which vary in number according to the maximum load and the amount of the safety rope tension weight.

The releasing carrier is placed on the counterweight and will therefore apply the *strong retarding* force of the car safety, even though the releasing carrier fails to release, due to faulty adjustment. The *strong retarding* force only is applied to the counterweight safety.

Whenever the current is cut off from the elevator, the electrical parts of the safety are operated, thereby applying the *light retarding* force. The mechanical actuating parts of the safety effecting the *strong retarding* force are continually kept in slight motion when the elevator is in operation, due to the different stretching of the hoist and governor

FIG. 38. DETAIL VIEWS OF AN ELECTRO-MECHANICAL SAFETY AS APPLIED TO A CAR

ropes. It is possible to remove all parts without disturbing the car platform, enclosure or car frame, thereby assuring easy access for inspection. In case of safelift elevators, a *strong retarding* force as described in paragraph *h* is applied by means of a parallel jaw double acting governor.

An electro-mechanical safety device such as just described has been designed and built by the Otis Elevator Company and subjected to a long series of experimental tests, the results obtained being remarkably successful. Some forty-nine elevators in the new Equitable Building have been equipped with these safeties and the consulting engineers, the builders and the New York Building Department have thoroughly and exhaustively tested them with entire and complete satisfaction to all concerned.

DISCUSSION

REGINALD P. BOLTON called attention to the remarkable development in the electric elevator, which now stands far and away at the head of all other types, and suggested that this meeting may be adequately described as the funeral service of the plunger elevator. He stated that there are 4,000 of the old hydraulic elevators still in service in New York, and referred to a scheme which Mr. Charles R. Pratt has developed for utilizing certain details of the hydraulic equipment in connection with electrical machines, instead of discarding the old hydraulic equipment entirely.

Mr. Bolton stated that the construction of the elevator

all stages of repair, and finally they will wear beyond repair and must go out, but many of them are still good for many years more. In looking into the matter in the last few months he found the problem to be as follows:

To change over to an electric elevator, one has to charge off 10 per cent to depreciation, and if the initial cost runs up, as it does some times, to \$4,000, \$6,000 or \$8,000 in an electric elevator, and if the owner charges off that 10 per cent depreciation, it wipes off the difference in saving in cost per car mile. He stated that it requires only a glance at any graphic recording wattmeter curve of kilowatt-hours per car mile to show that about 75 per cent of the power load on an electric elevator is inertia and not gravity. Modern electric

FIG. 39. CONSTRUCTIONAL DETAILS OF THE WEDGE-CLAMP SAFETY, ELECTRO-MECHANICALLY OPERATED

and the facilities with which it is provided cover only one half of the work which the elevator accomplishes, the other half of the time in which the elevator is in operation being devoted to the operations of loading and unloading passengers; he felt that considerable opportunity remains for improving elevator operation, and referred to such elements as the operator, his position in the car, starting and stopping the car, the control of doors and gates, systems of signaling, and the handling of passengers.

Mr. Bolton also discussed at length the difficult problems of passenger traffic in the elevators of the large New York City buildings, and quoted from his observations as to traffic peculiarities in other cities as well, and their effect upon the elevator service.

CHARLES R. PRATT called attention to the fact that there are still some 4,000 of the old hydraulic elevators in use in New York City, costing two or three times as much per car mile as the modern electric elevator would cost. They are in

elevators regenerate gravity to a very limited extent and inertia not at all; on the contrary, by the expedience of an armature shunt across the line, they take power to stop the load.

Hydraulic transmissions with a variable stroke pump for each elevator, a group of pumps driven by one power unit, offers, Mr. Pratt suggested, a practical regeneration of this inertia energy, but there appears to be no such pump as yet produced to meet all the requirements of this service, although experiments in this have been undertaken. Continuously revolving field or armature electric elevators offer somewhat the same regeneration of energy as the hydraulic transmission, but have not yet been proved to fill the bill.

He pointed out that if the inertia load on electric elevators could be balanced like the piston in a vertical cylinder engine, the kilowatt-hours per car mile could be reduced to about one-fourth the amount now expended. Hydraulic, mechanical, electric and flywheel action offer an inertia balance, but an underbalanced car cuts at the source by reducing

the mass and eliminating all inertia power load on the down trip.

Taking more than twice the maximum net gravity load appears at first thought to be wasted energy, he said, but when it is considered that high-duty hydraulic elevators and the Sprague-Pratt electric elevators, with their mechanical friction losses and no regeneration circuit, take about the same kilowatt-hours per car mile as the average modern electric elevator, the possibilities of high efficiency in underbalanced cars becomes worthy of serious attention.

The advantages, considered in detail, are:

- a Always driven by gravity on the down trip.
- b Controlled by armature resistance only, giving all ranges of speed, power circuit up and dynamic circuit down, using no armature shunt across the line to waste power at slow speeds and in stopping.
- c By use of an automatic potential switch it regenerates efficiently at full speed down, returning a large percentage of the power used on the up trip.
- d Reduces starting current on up runs by having less mass to accelerate.
- e No starting or running current used on down trip.
- f Requires but one field strength for all speeds, reducing size of motor.

If this be applied to a highly efficient modern electric elevator motor, either direct coupled or driven by helical or steep pitch worm gearing, Mr. Pratt stated the results would be interesting. In replacing old hydraulic with new electric elevators, and using an overbalanced car with a back drum counterweight or traction rope drive, all old hydraulic sheaves, overhead beams, counterweights, guides, vertical cylinders, etc., have to be altered, removed and scrapped, new parts substituted, and the entire hoistway brought up to date according to the Building Code laws. Whereas, by use of the underbalanced car, using the entire old hydraulic hoistway equipment undisturbed, even using the vertical cylinder for a continuous safety with a speed regulating valve in the circulating pipe, for water, oil or air, about one-half the total cost of the change over from hydraulic to electric is saved, with practically no interruption to the elevator service. Also a net profit is shown to the owner after he charges off 10 per cent of the initial cost against the amount saved in power and operating expenses.

There are four thousand old hydraulic elevators in New York City and ten times that number outside, waiting for a system that will finance the change to electric drive. Fig. 40 illustrates such a system applied to an old Otis machine. Two more grooves are added to the winding sheave, when the electric machine is located below with a regulating valve placed in the circulating pipe, using either air, oil or water. In the case of excess speed, this balanced piston operates to choke off the circulating pipe, and gives in effect very good safety. The control is very simple. All the magnets are down on the dynamic circuit. When the generated voltage equals or exceeds the line voltage, the potential switch is thrown over, and return is had for what it costs one to hoist.

ANDREW M. COYLE took exception to the statement by Mr. Lindquist in reference to the relative efficiencies of the direct driven traction machine and the gear driven machine. While no one doubts that for light duty and high speed the direct driven machine is more efficient, there is an immense field

in which the geared machine is highly efficient and in which the direct driven machine cannot be used at all. It is, therefore, he stated, not altogether fair to make the comparison based on a car speed of 600 ft. per minute. The geared machine using herring-bone or helical gears is highly efficient for all duties and speeds from 200 to 400 ft. per minute and this service covers the great bulk of elevator installations. He has been connected with the design and installation of several elevator machines using helical gears and has found that the gears were highly efficient and in every way satisfactory.

Mr. Coyle also took exception to the statement that these gears are only slightly more efficient than worm gearing. His reasons were stated as follows:

A worm gear is a special application of the wedge. The

FIG. 40 A METHOD OF APPLICATION OF ELECTRIC MACHINES TO OLD HYDRAULIC ELEVATORS

load moved is carried forward upon an inclined plane. The load which can be carried upon a single gear is limited. The working surfaces have only line contact, and when the load is enough to force the lubricant from this line, abrasion immediately sets in. To overcome this difficulty, the tandem worm gearing has been designed. By this arrangement the load is divided between two gears and the line of contact thereby increased.

It is obvious that, within limits, the steeper the incline, the higher the efficiency of the gear. The shorter the distance the load has to slide, the less will be the loss by friction. For this reason gears of high pitch angles give better results.

Worm gears doing heavy or continuous service, must be completely submerged in oil. A certain percentage of the power is expended in churning the oil. The power thus expended is constant for any given gear. When the load is

light, the power expended represents a considerable percentage of the whole work. On the other hand, when loads are light, the surface lubrication is better, and better results are obtained in the thrust bearings.

The *herring-bone* or *helical gear* is the most efficient gearing so far developed for elevator or any other service. These gears when properly cut are practically noiseless. The slight tendency to wear, is at the points of the teeth and tends to throw the load toward the pitch line where sliding friction is least. The helical gear works best when thoroughly lubricated; but it is a mistake to submerge the pinion. The very slight clearance allowed in these gears causes the oil to be confined in the teeth in such manner as to offer great resistance. It is best to use moderately light oil and to give the teeth a chance to drain before coming into mesh.

The efficiency of the worm gear is limited by the fact that the load must slide from five to ten times the distance it is lifted and that it is entirely dependent upon lubrication. In the case of the helical gear the sliding friction is almost negligible; the gears do not wear and cause back lash as is the case with the worm gears and the lines of contact and the strength of the teeth may be made sufficient to take care of any desired load.

An elevator machine using worm gearing, assumes an outline which lends itself readily to installation in buildings and for this reason as well as on account of low cost this type of machine is in some cases to be recommended. In point of efficiency the helical gear is entirely preferable.

ROBERT JOHNSON called attention to a condition frequently met with that has not been touched on at all in the paper, namely, the use of alternating-current in connection with elevator operation. The conditions referred to would, he said, hardly apply to an installation of alternating-current machines with regard to reliability or speed, and also as to the application of the brake gradually and slowly. This, he said, was a very important point, and he thought it would be very interesting to know whether alternating current is entirely successful in connection with high speed elevators, particularly in view of the fact that in certain parts of New York City alternating electric current is the only type of current which is available.

M. WM. EHRLICH, referring to the question of safeties supplied for the protection of elevators, said that while, of course, the standard safety devices usually installed in connection with an elevator become a good precaution, the records of the building departments and also of the different insurance companies, show that the elevator accidents from breakages of ropes or other parts of the apparatus are very small, the more recent statistics showing that about 80 per cent of the deaths in elevator accidents were caused by open or unlocked gates, or negligence in the operation of the gates by the elevator operator. The way to prevent that, he said, was to use a safety or automatic lock, which will necessitate the elevator making a full stop, and so arranged that before leaving the floor, the gate must be positively closed. That, he said, would prevent accidents caused by open doors and gates. A short time ago he had occasion to test an electro-mechanical device of that nature, and found that under actual service conditions the additional time consumed was $\frac{1}{4}$ second per trip, or only 8 seconds being lost in an average office building of 32 trips an hour.

Referring to the power consumption diagrams presented by the author, he pointed out that all these charts are, from the point of view of service, of paramount importance, and he therefore suggested that the values of stops per car-mile be converted to a more applicable basis as related to buildings; that is, instead of the unit of "stops per mile," these be changed to a unit of so many stops per number of floors.

Where in railroad service all stops are usually predetermined, he said, the first basis is serviceable, but in passenger elevator practice, where the installations occur in buildings of not only different total heights but varying story heights, and where the stops correspond to the demand of the passenger traffic at different parts of the day, it has been found by extensive observation that a unit ratio in which the number of stops are related to ten floors of travel, is the most expedient unit. Exhaustive studies of passenger elevator traffic have established the ratio of 4 to 10, a unit representing four stops in ten floors, as the average travel conditions in office buildings. Thus the observed number of stops in this class of building becomes the measure of proper division of the service when related to the unit of 4:10, which is the most economic point of operation, meaning, of course, current consumption.

Mr. Ehrlich asked that Mr. Lindquist supply the data to enable one to convert the stops per mile into the number of stops in ten floors. This would mean giving the height of elevator travel in feet and the number of floors served by the different cars. To illustrate the importance of the suggested unit, he quoted an example, assuming a case of 264 stops per mile. This would mean a stop every 20 ft. or approximately equal to a landing terminal at every second floor level in a building with 10 ft. floor heights. Then in a ten story building of such proportions this service would be equal to four stops in ten floors, corresponding to the average conditions prevailing in office buildings. Then assuming a 32 story building, with story heights averaging 13 ft. on account of several specially high floors, with the same elevator traffic, or 264 stops per mile, a service would be obtained under this condition of approximately 6:10, or six stops in ten floors. It will be interesting to note on this basis, by examining the charts presented, whether 4:10 is the mean point of current consumption, or whether any other point on the curve represents the most economical operation.

E. W. MARSHALL spoke of an incident in connection with a certain elevator under test in which the motor had proved not to be heavy enough. The elevator had been tried in the shop and the motor carried the load there, because between the hours of 12 and 1 p.m. every day it was stopped and the motor had a chance to cool off. When the elevator was put into a building and ran across these mountainous peaks which Mr. Lindquist has shown in his charts, it had no opportunity for cooling off and turned out to be unfit for the work which was expected of it.

ALFONSE A. ADLER asked two questions, one regarding the rate of acceleration of the elevator, and the other concerning the factor of safety on the ropes. According to the author's statement, he said it was about 12, but if the rate of acceleration of the elevator is considered, the stress on the rope, which is due, first, to the ordinary weight of the car, second, to the acceleration of the load, and, third, to bending

stresses in going over the sheaves, will appreciably cut down the factor of safety. There is an additional stress, aside from the bending stress and the force required to accelerate the car, which is not very frequently taken into consideration; that is, in the ordinary type of elevator, when the brakes are put on the rotating mass will be retarded, but the entire energy in the car must be taken up in the actual stress of the rope and he asked what that stress amounts to there.

H. F. GURNEY and C. R. CALLAWAY¹ (written). It was but a very few years ago that one's choice was restricted to some form of hydraulic elevator, if the rise was high, requiring a correspondingly high car speed, but recent invention and development have made the electric machine so far superior, particularly with respect to safety, the rapidity with which the car may be handled at landings, the smaller amount of space occupied by the apparatus, and the lower cost of operating, while retaining all of the hydraulic elevator's safety, reliability and smoothness of operation, that it has entirely displaced the latter from its former position of supremacy. While it is generally admitted, however, that the hydraulic elevator has been rightfully superseded by the electric, engineers are by no means agreed as to the best type of electric machine to adopt.

The only practical means of lifting an elevator car electrically appears to be by means of wire ropes, which are either wound up on a grooved drum, or driven by a traction sheave. These may not be smaller in diameter than about 50 times the diameter of the rope used, in order to keep the bending stresses low enough so that the rope will not be rapidly destroyed by breakage of the wires. Space conditions also make it necessary to keep the diameter of the drum large enough to wind up the length of rope required for the rise without making the length or face excessive, and in the case of traction sheaves, a diameter which is too small results in a decrease of tractive effort, with loss of proper control of the car on account of the resultant slippage, which also causes prohibitive wear of the ropes. We find from a consideration of these requirements that the speed of the drum or traction sheave in revolutions per minute for the car speeds used for rises of 150 ft. and upwards will fall approximately within the following limits:

Car Speed, Ft. per min.	Speed of Drum or Traction Sheave Rev. per min.
300	29 to 35
350	34 to 40
400	39 to 46
450	49 to 58
600	59 to 70
700	68 to 81

In order to drive the drum or traction sheave at these speeds electrically, two methods may be used: *a* an abnormally slow speed motor may be connected directly to the traction sheave, this arrangement being known as a 1:1 machine; *b* a moderate speed motor may be connected to the sheave through a suitable gear reduction.

We pass over, as unworthy of consideration, the arrangement in which the traction sheave runs at twice the speed required with direct roping, by the use of multiplying sheaves on the car and counterweight, driving these ropes

by a motor connected directly to the traction sheave, the combination being known as the 2:1 traction elevator. This method of roping is one which has long been used for slow speed freight work, and in this class of service it is not objectionable, but when applied to high-speed passenger service it becomes a makeshift which ought not to be tolerated. The power losses are greatly increased and the cost of current made correspondingly higher, while the cost of keeping the elevator supplied with ropes is exorbitant. The fact that it is used is, however, an admission that the higher speed motor has advantages over the abnormally slow, 1:1 type. A mechanical brake is needed on the machine to bring the car to a final stop after it has been slowed down as much as possible by the dynamic or electrical braking action of the armature, and as in the 1:1 and 2:1 machines, this must act directly on the traction sheave shaft, the same as the armature, it must be a very powerful one. The wear is severe on account of the heavy pressure with which the shoes must be applied to the pulley, and the adjustments are delicate and frequently required.

The difficulties encountered in designing a motor for an output of from 30 to 40 h.p., at a speed of 50 to 60 r.p.m., are so apparent that it is unnecessary to recite them here, and the engineer's best efforts must inevitably result in a ponderous armature, wound with a large number of turns of wire, which must be of large cross-section if the efficiency is to be anywhere within reason, and an enormous field structure to carry the heavy flux necessary to develop the torque required. It imposes an unreasonable load on the building structure, requires so much space that unless the cars are unusually large it is necessary to install machines of this type on two levels, requires very expensive supports and pent-house construction, with a traveling crane of about 5 tons capacity over them to handle the pieces when taking a machine apart, and results in the machine being out of service for days at a time in case repair is necessary. It has, moreover, the poor commutation resulting from carrying heavy currents through so many armature turns, causing a high reactance voltage, and makes it very difficult to keep the commutator in good condition. A motor of this type will have so much copper on its armature that the internal voltage drop or rise caused by its resistance will result in a wide variation of speed, between the extremes which will be met in service, one of which is lifting a heavy load, when a heavy current will be drawn from the line, and the other, lowering a heavy load, when a heavy current will be generated into the line. The reduction of the speed in the first case, and the increase in the second, will be excessive, and this poor speed regulation is very undesirable in passenger service.

In any high speed elevator, it is necessary to reduce the car speed just before stopping, to a fraction of the normal speed, in order to make it possible for the operator to stop the car accurately at the floor level, and to reach the terminal landings without danger of striking the buffers or overhead work. To accomplish this reduction in speed, there are two possible methods which may be employed: *first*, an increase in the magnetic flux through the armature, and, *second*, a reduction in the voltage across the armature terminals. The former is, of course, recognized by all as the preferable means of affecting a variation in motor speed, and is in general use under all imaginable conditions, but this method cannot be applied to the 1:1 machine to a sufficient extent,

¹ Superintendent, Gurney Elevator Co., New York.

The advocates of this type will admit that it is simply out of the question to make the speed with maximum field strength less than about 45 r.p.m., which, with a traction sheave 33 in. in diameter, will give a car speed of about 390 ft. per min. As this is entirely too high a speed from which to make landings accurately, it becomes necessary to resort to the other method to reduce the speed still further; that is, to get a lower voltage across the brushes by some means. This might possibly be done by using a multiple voltage power supply, but the application of such a system presents so many difficulties, requiring complicated controlling apparatus, with special generators to supply the low voltage, that it has not been attempted.

The accepted scheme is to use resistances, one in series and one in parallel, with the armature, with means under the operator's control for varying them as required by the load in the car and the direction in which it is moving, to reduce the speed as much as may be desired. A single resistance in series with the armature cannot be used, because the counterweight is always made heavier than the empty car by an amount equal to the average load, in order to reduce to a minimum and equalize as far as possible the work done by the motor, which thus acts as a generator and returns power to the line when the car runs up with no load or a light load, or down with a heavy load. At such times the series resistance alone would result in an increase of speed instead of a decrease. In considering the circuits with this arrangement, it must be borne in mind that with any given condition of load and direction of movement, the current flowing through the armature will be a constant, regardless of whether the full line voltage is impressed upon the armature, or only a part of it by connecting resistances in the armature circuit, provided that the field excitation remains unchanged, although it is of course reduced by increasing the field strength. This is due to the fact that a practically constant torque is required to keep the elevator system in motion at any speed, and this torque is a function of the field flux and armature ampere-turns only, the speed alone varying with a change of armature voltage. The armature current when running at the slow speeds obtained by the use of the series and shunt or by-pass resistances can therefore in no case be less than that required to run the elevator under the same condition of load and direction of movement with the full line voltage across both armature and field terminals, that is, at maximum field strength.

The great waste of power in reducing the speed by this method is self-evident, but is so important and so much more than it would appear to be from a casual examination, that a few specific cases will be pointed out, in comparison with the energy required under the same conditions by a geared machine having speed control by field variation only. It will be assumed that the normal car speed is 600 ft. per min., and that both machines have traction sheaves 36 in. in diameter, running therefore at about 64 r.p.m.; that the 1:1 machine is driven by a motor so designed that the sheave runs at 45 r.p.m. at maximum field strength, giving a car speed of 424 ft. per min.; and that the geared machine is driven by a motor so designed that the sheave runs at 18 r.p.m. at maximum field strength, giving a car speed of 170 ft. per min. The latter speed is low enough to permit stopping the car at landings with sufficient accuracy, but as 424 ft. per min. is entirely too high, armature resistances must be used with the 1:1 machine to get a further reduction of speed. In

making the comparison the controller contact, brush, and armature copper resistances will be disregarded, as these, while having a slight bearing on the case, are not of sufficient importance to affect the results materially. The assumption will also be made that both machines will take the same armature current to lift a given load in the car at a given speed, provided that this speed is not less than 424 ft. per min., the full field strength speed of the first machine.

No diagram is necessary to show the circuits when no armature resistances are in use, as the brushes are connected directly across the line. Currents flowing from left to right in Fig. 41 showing the connections of the armature resistances, are marked plus (+) in the Tables, and those flowing from right to left are marked minus (-). Line currents marked plus (+) therefore represent power drawn from the line, and when marked minus (-) indicate power returned to the line, and this is also the case with the line currents given for the second machine, with which no armature resistances are used, and for the first machine when running with full line voltage across the armature. The overbalance, or excess of counterweight over the weight of the car, has been assumed to be 1000 lb. for both types, although the geared machine is usually operated with less overbalance

FIG. 41 DIAGRAM OF SERIES AND BY-PASS ARMATURE RESISTANCES

owing to its larger sheaves and greater traction. The net loads which must be handled by the machine, given in the second column, are therefore 1000 lb. less than the gross loads in the first column, being indicated as positive when the greater load is on the car side, and as negative when the excess is on the counterweight side. Considering movement of the car upward as positive and movement downward as negative, if the product of the signs representing load and direction is positive, the machine will be called upon to do work, as it will be lifting the weight which is greater, but if negative, the greater weight will be descending, and current will be generated in the armature.

A comparison of these figures shows that for every condition, the machine using the armature resistance, that is, the 1:1 or gearless type, takes more power as soon as these are connected in the circuit, and even though the other machine may be generating current at slow speed and returning it to the line, this gearless machine will still require a very considerable amount of power to be supplied. The moment the shunt resistance circuit is closed, whatever current the armature generates flows around it, and the reduction in total power used by the elevator that might be secured, is lost. The machine runs under this slow speed condition every time a terminal landing is approached, the automatic limit switches being set to slow down the machine at a safe distance from the floor and to cover all conditions of load, this distance is greater than an operator would require to stop the car at an intermediate floor, although in making inter-

mediate stops this condition obtains and depends upon the operator's skill in judging the correct distance from the floor to bring the car switch to the *slow* position.

In Table 1 it has been assumed that the resistances could be varied just as required to get the desired 90 volts across the brushes, but in practice this cannot be done so accurately. Approximations must be made and the speed with different loads will show a wide variation. It is necessary as well to depend upon the operator's good judgment to select the correct point on his car switch for the load in the car at the time. In comparison with this uncertainty, we have, in the geared machine, a fixed maximum field strength, giving a definite slow speed with all loads automatically, subject only to the slight variations found in a well-designed shunt motor, which are negligible.

Considering now what becomes of the kinetic energy in the moving masses when reducing the car speed by either of the methods that have been described, we find that when this is

opened with the car running at 170 ft. per min. is of course lost in the dynamic braking resistance and the mechanical brake, but as this is only about 20 per cent of the original total accelerating energy, its loss is comparatively unimportant.

The armature shunt resistance also takes its toll every time the car is started, as well as when stopping, for having been left connected across the armature when the line circuit was opened, it is still there when the line is closed, and until the contactors controlling it have operated, part of the starting current flows through it, doing no useful work.

Now may be considered the possibilities of the alternate method first suggested, that is, the use of a moderate speed motor, driving the traction sheave through a suitable gear reduction. It is well known that machines of this kind, employing worm gearing, have been in general use for many years, and have proven beyond question their adaptability for service at moderate speeds. The durability and efficiency

done by strengthening the field, with the armature still connected directly across the line, exactly the same result is obtained as when an unbalanced load is driving the machine; that is, current is generated in the armature and returned to the line, or if the machine is lifting a heavy load there will be a reduction in the line current, which amounts to the same thing. All of the energy that was used in accelerating the complete elevator system from the full field to the maximum speed will be returned, less the losses in the armature and gears only. As this kinetic energy varies as the square of the velocity, it will be found that the proportion of the total accelerating energy that will be thus returned by field strengthening, for the two machines we have been considering, will be 50 per cent for the first machine of the gearless or 1:1 type, with a full field car speed of 424 ft. per min., and 80 per cent for the second or geared machine, with a full field car speed of 170 ft. per min. The remaining kinetic energy cannot be usefully recovered from either machine. Although the first machine will be slowed down to 170 ft. per min. before disconnecting it from the line, thereby generating energy in the armature equal to about 30 per cent of the original total accelerating energy, it has been seen that this will all be dissipated in the resistances; none of it can be returned to the line on account of the shunt around the armature, but on the contrary, additional current will be drawn from the line through the series and shunt resistances. The energy remaining in the system when the line circuit is finally

of well-designed worm gearing are quite surprising, and there is no doubt but that it would be entirely satisfactory for any car speed allowed by city regulations, if properly applied. The writers believe that worm gearing will be used for a long time to come for moderate speed machines, but when the car speed is 350 ft. per min. or more, it becomes desirable to use another kind of gearing, which recent developments in manufacturing methods have made it possible to produce economically and accurately, having a much higher efficiency and

extreme durability, with perfect certainty of smoothness of operation, when properly designed and constructed. By this reference is had to the double helical or herringbone gear reduction.

This form of gearing is now so well known that it is unnecessary to describe it in detail, as since it was found that it could be produced so easily by the hobbing process, it has rapidly come into general use, and has been applied with entire success under the most exacting conditions of service, such as driving the propellers of steamships, where the safety of the ship is dependent upon the unailing transmission of the power controlling its movements; or for reducing the speed of steam turbines, in which the velocity is so high that no other form of gearing can be used; or for driving rolling mills, where the severe shocks would be destructive to any other kind of gears. It owes its remarkably high efficiency and perfectly smooth operation to the continuous rolling pitch line contact of the teeth, which are so proportioned that several are always in engagement at the pitch line, at which practically all of the pressure between the teeth is transmitted without loss of power from sliding or slipping between the load-carrying surfaces. This absence of slipping also explains why gears of this type are practically free from wear.

Here it is desired to correct the impression left by the author's curves of the efficiency of herringbone gears. These apparently indicated that the gears have an efficiency of only 88 to 91 per cent—values far below those regularly obtained in good practice, which are found to be from 98 to 98.5 per cent, as determined by the writers' tests. These figures are substantiated by numerous other tests made by competent engineers, showing that when properly designed and manufactured, gear reductions of this type may confidently be expected to show an efficiency of 98 to 99 per cent. A report of tests that may be cited is one made by the Westinghouse Machine Co. on a gear reduction suitable for the propeller drive of a steamship,¹ which test showed an efficiency even higher than 98 per cent. The author said that about 1.5 h.p. was required for the agitation of the lubricating bath in which the gears run, but such a loss of power is many times the attainable minimum with thorough lubrication, which is secured by the use of a small amount of relatively light-bodied oil. As a matter of fact, the total power lost in the gear reduction complete, including the rolling tooth friction, oil agitation, and turning the main shaft in its bearings, is only about 0.5 h.p. at full load; that is, when transmitting about 35 h.p., if the gears are properly designed and manufactured.

The author also said that worm gearing was preferable to double helical gearing because it offered greater certainty of smoothness of operation. Emphatically this is not the case, and in any elevator with a machine employing well-made gears of this type, it is impossible to detect their presence, as the smooth floating motion of the car is fully equal to that of any hydraulic elevator, while on the other hand it is a well known fact that worm gearing used in elevators very often results in a trembling motion of the car, which it is difficult to remedy. In answer to the implication that gears should not be used if it is in any way possible to get along without them, a well-known manufacturer of apparatus using herringbone geared drives is quoted herewith: "While

there is a general and natural objection to the introduction of gears where they can be avoided, yet here, as in all branches of engineering design, the advantages and disadvantages of one form of construction have to be balanced against those of another before a final judgment can be passed. In other words, the use of gears eliminates certain undesirable features; therefore, if gears can be made that will perform the duty, with low cost for maintenance, high efficiency and requiring little attention, is not the use of such gears the logical procedure?"

It is conceivable that if one setting out to design an automobile, allowed the obsession that gears must not be used to run away with his good judgment, he might succeed in producing a car that would run, but no right-minded engineer considers such a course for a moment. He designs a motor for the speed at which it will show the best operating characteristics, and transmits its output to the driving wheels through suitable gearing, properly designed for the functions it must perform. The prediction is hazarded that if electric cars come to take the place of the gasoline cars now generally used, the design adopted will not be one using a motor directly connected to each rear wheel. Outside of this gearless elevator, we have no examples of moderate or slow speed machinery driven by direct connected electric motors. Such a construction is used only for high speed machines, such as speed lathes, grinding and buffing wheels, and the like, which run at speeds equal to those of motors of standard design.

The author gave some figures on the accelerating energy required in starting a machine of the geared type as compared with a 1:1 machine. He gave 3060 foot-pounds as the energy required for the sheave and gear alone, and a total of 13,400 foot-pounds for the complete machine, against 2450 for the complete 1:1 machine. There is evidently some discrepancy in these figures, as it is apparent at a glance that the 1:1 armature with its traction sheave and large brake pulley will require far more accelerating energy than the much lighter gear and sheave, running at the same number of revolutions per minute. These figures really should be about 2200 foot-pounds for the gear and sheave, and about 3800 foot-pounds for the complete 1:1 machine.

While it is admitted that the geared machine will require somewhat more energy for acceleration than the 1:1, the difference is shown in correct relation to the total work of acceleration when added to the energy required to lift the unbalanced load in the car during the accelerating period of 2.5 or 3 seconds, and that required to accelerate the vertically moving masses, consisting of the car, load, counterweight, and lifting and compensating ropes, the total weight of these being, on the average, about 14,000 lb. As the maximum net load the machine will lift is usually about 2000 lb. and the distance traveled by the car while accelerating about 9 ft., the work the motor must do to overcome this resistance will be 18,000 foot-pounds, while the work of accelerating the 14,000 lb. of vertically moving parts to a speed of 600 ft. per min., or 10 ft. per second, will be about 21,800 foot-pounds. Adding to these the accelerating energy for each of the machines, including an allowance for the idler and compensating rope sheaves, we get for the total work done by the motor during the time taken to accelerate the elevator, about 41,800 foot-pounds with the 1:1 machine, and about 56,500 foot-pounds with the geared machine, these figures being roughly in the ratio of 4 to 5. The kinetic energy in

¹ Engineering News, December 30, 1903.

all the moving masses is about 26,800 foot-pounds with the 1:1 machine, and about 38,500 foot-pounds with the geared machine.

It has previously been pointed out, however, that when slowing down preparatory to stopping, a much greater proportion of this energy is returned to the line by the geared machine, which has field control only, than by the 1:1 machine, using armature resistances. It was shown that the geared machine would return to the line 80 per cent of the original total accelerating energy, less armature and gear losses, so, assuming these to be about 6 per cent, we will get credit at the wattmeter, or at some other machine, electrically, of course, for about 29,000 foot-pounds. The balance, or net charge for acceleration, is therefore 38,500 minus 29,000, or about 9,500 foot-pounds. But the 1:1 elevator will return only 50 per cent of its energy, so allowing for the same loss as above, about 12,600 foot-pounds will be returned, and the net charge against this machine for the start is therefore 26,800 minus 12,600, or about 14,200 foot-pounds,—just about one-half more than was charged to the geared machine, which has again shown its superiority. It should be remembered, however, that this does not take account of the loss of power in the 1:1 machine in the current drawn from the line while the armature resistances are in the circuit.

A careful consideration of the advantages that are secured by the use of a moderate speed motor which may be designed for any desired speed variation entirely by means of field weakening, without exceeding reasonable limitations as to weight and space occupied, in combination with a double helical gear reduction driving a traction sheave which may be as large in diameter as desired, as against the direct connected, or 1:1 machine, with the many disadvantages that have been pointed out, will, it is felt, convince any fair-minded engineer that the former is the logical construction to adopt. The results which have been obtained in actual service with the herringbone geared type traction elevator, embodying these principles, have proven beyond a doubt the correctness of this conclusion, as the ease of control, high efficiency from line to load, and small energy consumption per car mile have not only equaled, but exceeded all expectations. A line-to-load efficiency within 0.2 or 0.3 of 77 per cent has been obtained with machines which had been running only a short time, and as the efficiency invariably rises after the elevator has been in service for a few months, it is practically certain that an efficiency of 80 per cent will be reached. High speed machines of this type in office building service are operating regularly on the remarkable low power consumption of from 1.8 to 2.4 kilowatt hours per car mile, with acceleration and retardation as rapid as may be desired, and giving perfect satisfaction to owners and tenants.

In conclusion, some of the advantages of the double helical geared machine, as compared with the 1:1 machine, may be summarized as follows:

- a* Less space occupied in the building.
- b* Less expensive supports and pent-house construction.
- c* No traveling crane needed.
- d* More efficient motor design possible.
- e* Commutation better.
- f* Mechanical brake less troublesome.
- g* Control of car speed secured entirely by field-weakening, against wasteful armature resistances.

- h* Car runs at a definite speed when running slow, insuring more accurate stops.
- i* Higher line to load efficiencies.
- j* Less energy required per start and stop.
- k* Lower cost of operating on account of smaller energy consumption per car mile.
- l* Less rope wear.

In regard to the objections that have been raised to the use of gears of the type selected for these machines, attention is called to their general and constantly increasing use under the most severe and exacting conditions of service, with entire satisfaction; their remarkably high efficiency, with losses so small that they are offset, many times over, by economies they permit in other parts of the apparatus; their extreme durability, running for long periods under heavy loads and showing practically no signs of wear; their perfect smoothness of operation, which makes it impossible to detect in the car that gears have been used in the machine; their freedom from noise and vibration; and the fact that they require no attention other than an occasional small supply of lubricant. The objection to the use of gears of such qualities are so slight as compared with the many substantial advantages that their adoption for the purpose is considered fully justified, and it is felt that as the characteristics of the machine they make possible become more generally appreciated, they must inevitably be accepted as the logical and best type for high-speed service.

THE AUTHOR. In reply to the question with reference to the rope strain, I might say that by the remark that under ordinary conditions the safety factor was never less than 12, I meant the apparent safety factor with the load at rest. I did not in that statement take into account the additional stress due to acceleration and bending of the rope. That will, of course, materially reduce the apparent safety factor. If the acceleration curves shown for one particular elevator are analyzed, the additional stress due to acceleration can be determined. The stress due to bending over the rotating sheave has been approximately determined and it is not as high as is usually thought. The reason for this is that each wire is not subjected to the same strain by bending it over a sheave, as if it were a single straight wire bent over the sheave. The wire is wound up in a double spiral; the first spiral is the original spiral in the strand, and the second spiral is part of the strand itself, making really a coiled spring wound up into another coiled spring, which, of course, materially reduces the stresses due to bending.

During the last two years I have steadily tested ropes of different construction to determine the actual stresses and to determine the wearing qualities, etc. It is a subject that is altogether too deep to touch on in a few minutes, because one cannot do it justice. I may say, however, that the testing of the ropes referred to brought about some most surprising conclusions. Due to these tests I think it may be predicted that in the near future ropes employed in connection with elevators will be of different construction from those which have been used up to the present time.

Going back to the question of safety factor, if the apparent safety factor is 12, I may say the real safety factor is hardly over 8.

The rate of acceleration can be determined from the curves illustrated. I do not remember what the rate was in any par-

ticular instance, nor can I say offhand what the rate of acceleration is in any particular building, because it varies considerably. It varies with the weight of the car, the rise, the quantity of rope, and also with the service. I may say that in the Hudson Terminal Building, for example, was observed the most rapid acceleration of any electric elevators in New York City. I have determined the rate of acceleration of these elevators, and if of any particular interest it may be published at a later date.

In reference to the employment of alternating-current in electric elevator service, up to the present time no alternating-current elevators of the direct connected or gearless traction type have been put upon the market. Those that have been put on the market have been of the geared type, for speeds up to 350 ft. per min. approximately. For 250 to 350 ft. speed, two speed alternating-current motors are employed, with a speed variation of from 1 to 3 down to 1 to 4. The slowing down or the changing in speed from the full speed down to one-third or one-quarter speed is obtained by rearranging the connections of the motor in such a way as to change from a small number of poles giving the high speed to a large number of poles giving the slow speed. During this change of speed, power is actually generated back into the line, in a similar manner as in the case of a direct-current machine, when the motor field is strengthened for the purpose of speed reduction.

There was at first considerable difficulty in eliminating an objectionable shock due to reducing the motor speed to one-quarter in one step, but by proper design of motor and controlling apparatus, this was successfully accomplished.

With reference to the smooth application of the brake, no known method, at least no method known to me, has been used for magnetically retarding an alternating current brake. There we have to resort to dashpot retardation. In the majority of cases, the brake magnet parts are enclosed in oil tight casings and the brake magnetic cores are utilized as plungers to obtain dashpot action. So far as I know, this is about the only way at the present time by which a comparatively smooth application of the brake can be accomplished in connection with alternating current machines.

I may say that last year I built a gearless alternating current traction machine, but it was not designed on exactly the same lines as the direct-current gearless traction machine. It consisted of one continually revolving motor and one starting when the elevator was started and running when the elevator ran. Half of the outfit consisted of an alternating current motor, which at the time that it acted as a motor acted also as a converter. The other half of the machine consisted practically of a direct current motor having a revolving field with unusually great field variation and speed regulation. The machine was built and tested, and, so far as the speed control was concerned, it was perfect. Field regulation, from no speed up to full speed could be had; in other words, any desired speed could be obtained without resorting to control of resistance in the armature circuit. On the other hand, the losses were comparatively high and the efficiency was not very good. As far as smoothness of operation was concerned, the machine was entirely successful, but the cost of operation was comparatively high. As a matter of fact, considering first cost and power consumption together, I do not consider the machine a commercial proposition: as good results and perhaps better could be obtained by changing the alternating current by

means of converters or motor generator sets into direct current and then operating direct-current elevators. The reason why this line of experimentation was temporarily abandoned was simply because it appeared very doubtful whether this type of machine could be of use commercially, even though, from a technical point of view, it proved a complete success.

The discussion by Messrs. Gurney and Callaway lends itself to comment. Presumably, in their remarks, they did not mean to imply that the use of driving sheaves a few inches less in diameter than those assumed would result in a decrease of tractive effort, slippage and undue wear of ropes. Under normal condition, the unbalanced load which can be lifted by a traction sheave without slippage of ropes depends on the arc of contact in degrees. It is independent of the diameter of the sheave, except to a slight extent; that is, increasing the diameter of the sheave may reduce the pressure per unit length of rope in contact to the extent of allowing the film of lubricant to reduce the effective traction.

Having omitted mention of the number of starts per car mile made by the elevator, their reference to a consumption of 1.8 to 2.4 kw.-hr. per car mile is somewhat lacking in significance. This will be apparent upon referring to curves in Figs. 28 and 29.

The gearless 1:1 traction machine is intended primarily for high speed, high rise service. For this service, on account of its uncommonly high efficiency (especially with average or less than half load), low power consumption and satisfactory operation, it far excels all other types of elevator machines yet developed. It is not intended to supplant the geared type of machine in its particular field of comparatively low speed and rise. In other words, the interests of clients are best served by having both types available for choice, depending upon a careful consideration of particular requirements. Manifestly, there is a field intervening that of the gearless 1:1 traction and the regular worm geared type of elevator which may be covered by either of them. When, therefore, the load required is heavy, the speed desired is between 250 to 450 ft. per min., and the service is severe—making a reduction in power consumption an important consideration, justifying a reasonable increase in first cost of plant—the use of a gearless 2:1 traction machine is most appropriate. This 2:1 type of machine combines the advantages of high efficiency (with average as well as full loads), comparatively low kinetic energy and consequent low power consumption with requirements for lower speed and corresponding heavier loads.

The efficiency of a complete installation of a gearless 2:1 traction machine is only slightly less than that of a 1:1 equipment. The decrease is due to the bearings of the sheaves mounted on the car and counterweight. These bearings are of the ball bearing type, and the friction and oil losses thereof are evidently less than those due to worm or herringbone gears. The machine of the 2:1 outfit is practically the same as that of the 1:1. The 2:1 roping is used to obtain car speeds of 250 to 450 ft. per min., instead of speeds of 500 to 700 ft. per min., usual with the 1:1 outfits. The rope speed also is practically the same in both. Both, therefore, employ low speed motors; and it should readily be apparent that the use of a 2:1 arrangement is not "an admission that the higher speed motor has advantages over the abnormally slow."

Exception has been taken to items in the tabulated comparison of the kinetic energies of a herringbone geared and

a gearless machine, presented in the paper. These tabulations were intended to be indicative of two particular machines suitable for the same load and speed. The herringbone gear was large in diameter and of substantial construction. Its weight resulted in the high energy of 2060 ft.-lb. This result, as well as all the other kinetic energies given, was derived from careful tests made in the manner described. They represent actual facts and not mere assumptions. Since it appears of interest, a similar tabulation of the complete installation, also, is here presented:

	Kinetic Energy in Foot-pounds (600 ft. Car Speed)	
	Herringbone-gear Machine	Gearless Machine
Motor armature, . . .	7420	2450
Brake pulley, . . .	2920	
Driving sheave, . . .	1000	
Herringbone gear, . . .	2060	
Secondary and compensating sheaves	1865	1865
Car and counterweight on balanced load condition,	15,500	15,500
Ropes,	880	880
Total,	31,645	20,695

The ratio between these totals is as 6.13 is to 4 and not 5:4, as indicated in the discussion. As the use of the herringbone-gear or the gearless machine does not entail material differences in the design or layout of car, counterweight or other hatchway units, a comparison of the differences in the machines only was deemed most representative of their relative merits for elevator service and possible effect on power consumption.

Since the kinetic energy of a low speed motor is less than that of a high speed motor, the former may be brought to rest by the dynamic and mechanical brakes, with relatively less electric and friction losses and relatively less wear on the brake shoes, than may the high speed motor, even though the brake itself be, as a matter of fact, larger and more powerful.

That "the difficulties encountered in designing a motor for an output of from 30 to 40 horsepower, at a speed of 50 to 60 rev. per min.," may be successfully overcome is perhaps fully illustrated by Figs. 6 to 9 and the curves in Figs. 10 and 11. Fig. 11 relates to a motor rated at 75 h.p. running at 89 r.p.m., which had an efficiency of over 90 per cent at anywhere from merely 30 per cent of its capacity to considerable overload. The variation in car speed when ascending and descending with full load is within 5 per cent of the average speed.

In the discussion, there appears to be advocated reduction in motor speeds of $3\frac{1}{2}$:1 (64:18) by means of field regulation only. From our experience with high speed shunt field motors, we should judge that so great a reduction by means of field regulation only would prove somewhat unsatisfactory, particularly for normal running conditions. With the low speed motors we use, we have, however, successfully accomplished a speed reduction for stopping of fully 2:1 by means of field regulation only.

It should be noted that a small amount of speed reduction by field regulation is more effective in stopping a low speed motor than is a greater proportionate speed reduction by field regulation with a high speed motor. This is due to the fact that facility, or difficulty, in making accurate stops depends on the amount of energy stored in the moving parts, rather than merely on their speed.

Their argument tends to convey the idea that the energy required for accelerating the elevator masses during the period of starting is available for recovery during the period of stopping, and that the gearless machine, having less speed reduction by means of field regulation, dissipates in armature resistance more of the energy available for recovery than does the geared machine, and therefore consumes in effect more power. Their conclusions appear to have been influenced also by the erroneous assumption that series and bypass armature resistances are employed during starting.

For investigating the accuracy of their conclusions, an example may be given. For instance, let us consider the kinetic energies of the two installations to be as already tabulated, namely: 13,400 ft.-lb. for the herringbone geared machines, 2450 ft.-lb. for the gearless machine and 18,245 ft.-lb. for the hatchway units. Let us assume the motor and contactor efficiency of each installation to be 85 per cent, the gear and hatchway efficiency of the geared machine 75 per cent and the hatchway efficiency of the gearless 85 per cent. Moreover, let us assume a speed reduction by field regulation only of $3\frac{1}{2}$:1 for the geared machine and 2:1 for the gearless.

Manifestly, the energy required by the motor for accelerating the elevator masses of the geared machine may be expressed as follows:

$$13400 + \frac{18245}{0.75} = 44,300 \text{ ft.-lb.} \quad (1)$$

and that of the gearless:

$$2450 + \frac{18245}{0.85} = 28,200 \text{ ft.-lb.} \quad (2)$$

Evidently also, the energy available for recovery during the period of speed reduction before stopping may, for the geared machine, be expressed as

$$0.85 (13400 + 0.75 \times 18245) (1 - 1 \div 3.5^2) = 21,100 \text{ ft.-lb.} \quad (3)$$

and, for the geared machine:

$$0.85 (2450 + 0.85 \times 18245) (1 - 1 \div 2^2) = 11,450 \text{ ft.-lb.} \quad (4)$$

Finally then, the difference between equations (1) and (3) and between (2) and (4) will indicate the net amount of power consumed by each elevator during starting and stopping. That is, the net amount consumed by the geared machine may be represented by $44,300 - 21,100 = 23,200$ ft.-lb., and that consumed by the gearless, by $28,200 - 11,450 = 16,750$ ft.-lb. The latter is only about 72 per cent of the former. This example indicates that even with less field regulation, the gearless machine consumes considerably less power for starting and stopping; and it is obvious that its efficiency is superior during running.

In response to Mr. Erlich's request the story heights of the Adams Express Company's building averaged 13.2 feet.

APPLICATION OF ENGINEERING METHODS TO THE PROBLEMS OF THE EXECUTIVE, DIRECTOR AND TRUSTEE

BY DR. HOLLIS GODFREY, PHILADELPHIA, PA.

Member of the Society.

THE problem considered in this paper is the expression of an endeavor to determine the methods by which the service of a consulting engineer may be made of greatest value to the executive of a corporation, or to a board of directors or trustees, during an interregnum in the executive office. In taking a more or less comprehensive view of problems which have confronted certain executives, and mapping out plans coöperatively with them which they could present to their directors, to their subordinates, and to their constituents, I have been forced to a regular method of procedure made practicable through coöperation of the executive and the consulting engineer. This method, which, after an experience of several years, has proven its value in money and in service, is briefly as follows:

- a The defining, on the basis of facts shown by engineering study, of the policies of a business.
- b The expression in simple, usable form of the definitions obtained.
- c Construction on the basis of the studies made.

THE NEED FOR DEFINITION

The need for an executive to have definitions before he can make decisions is often forgotten. No executive is doing the most he can do for his business until he has obtained his definitions, by having his business fully surveyed and his fields of action selectively mapped, until he has located to the best of the present state of engineering and of industry the places where waste exists and where the greatest possibility for profitable development lies.

Such broad study, to be fully effective, must come from the coöperative use of the best methods known to engineering and to industry, through such coöperation between the industrial executive and the consulting engineer as shall combine the best of the inside industrial view of the business in question and the best of the outside view of applied science. Such a study must include or be followed by the vital but often neglected comparative and selective studies, which show what pays and what does not. To define what is to be kept and what dropped is essential to a successful business. Too often the rule is to keep everything; such a policy may have been possible in the old days of big profits, but it is no longer possible today.

THE NEED FOR EXPRESSION

To express a definition is almost, or quite, as necessary as to define, for an executive has especial reason to make his meaning clear. First and foremost, his policies must be so clear in his own mind that he can properly place them before the board of directors or trustees, if these bodies are to legislate wisely and well upon the policies placed before them. Again and again problems involving very considerable sums of money come before boards of trustees and directors, where the time of discussion of the question

is limited to from one to three hours. The executive is the person to bring these problems before the board; and in order to choose wisely between different policies, in order to enable the directors to see what should be done, and to lay down a policy for the institution, the facts used must be so well chosen and selected that there can be no question of their value, and so clearly and so completely presented that their meaning can be given to a board in the shortest possible space of time.

Expression to the board of directors is but one of the problems. An executive has another duty which is often forgotten,—whether he will or no, his immediate task must be largely that of training his subordinates, of educating the men who are to work with him in the different policies of the business so that the whole staff shall work in harmony and each one understand what is behind the different policies which affect the sales, operating, and accounting departments. If the executive has not defined and expressed his policies in so simple a fashion that all his force is working in harmony, the lost motion ensuing means a loss in money which is amazing to contemplate. In many corporations, the executive has another duty, because in this day of the interest of the public and of the Government in corporation affairs, it is again and again essential not only that proper facts should be chosen, but also that those proper facts, once chosen, should be properly translated and expressed in a form which will reach a given audience, especially the broad audience of the public. Too often today such selection and expression of facts is wanting, and instead a theory or a case is presented, which may be met and conquered by another theory or another case.

COÖPERATIVE CONSTRUCTION

Money saving and money making—time saving and improvement of service—all these are intimately concerned with proper definition and expression of the facts about a business. When such definition and expression has been made, strong constructive work can be done and all three factors, definition, expression, construction can best be upbuilt through the application to industrial needs of the best that modern science and scientific methods has produced.

It cannot be too strongly emphasized that such applications of science to industry as are here outlined can best be accomplished through the coöperative efforts of engineers trained for years in science, in various types of industry and in the application of science to industry and of corporations willing to devote to such coöperative endeavor the cordial assistance of employees trained for years in the details of their own business. Neither from without nor within can the best results be secured. Advances can best be made through the welding together of the two types of knowledge possessed by two groups of men, one possessing general knowledge of science and industry and one possessing specific knowledge of a given business.

Presented at the New York local section of the AMERICAN SOCIETY OF MECHANICAL ENGINEERS on March 9, 1915.

METHODS OF PROCEDURE

There are six divisions, as I have seen them develop, which very much concern a consulting engineer who is serving any corporation along these lines. The final thing is, of course, the decision, and it is the executive or the board who knows five or ten per cent more than the other man who decides promptly, and in most cases decides rightly. It is, then, a function of the consulting engineer to present such facts to the executive that the basis of the decision made may be as sound as possible; he should place before the executive:

- a A general preliminary coöperative study of the field to determine what lines are most worthy of study.
- b A coöperative determination of what facts should be

every executive must realize the fact that it is his task to determine the internal policy and the external policy of his company, and that those policies, which make up the policy of the business, must rest primarily upon the history of that business and upon the facts of the business and its relation to its world. He should also realize that he can best obtain the necessary data as to both history and facts through the coöperative assistance of the engineer. No consulting engineer can possibly know as much of a given business as can men who have been trained for years in that business; but it is equally true, though sometimes forgotten, that no business executive can know as much of scientific methods as applied to industry as the engineer—each has his own knowledge, his own training, his own experience. One has

PRELIMINARY WORK

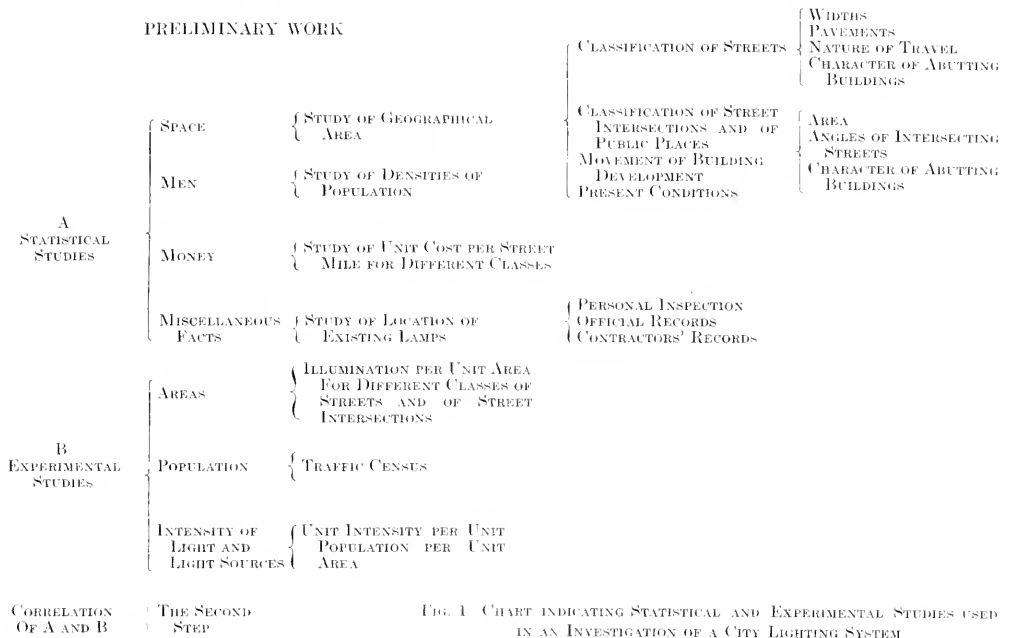

FIG. 1. CHART INDICATING STATISTICAL AND EXPERIMENTAL STUDIES USED IN AN INVESTIGATION OF A CITY LIGHTING SYSTEM

known about the lines selected and a definition of the periods most worthy of study on the basis of the preliminary study.

- c A careful collection and intensive study of the facts existing in the lines chosen for the periods determined.
- d The translation of the facts collected and studied in the light of their relation to the other departments of the business.
- e The expression of the facts studied and the results obtained, in the briefest and clearest way.
- f A method for the constructive use of the facts obtained and where necessary, an expression of the facts in a form intelligible to the special audience which needs most to know them.

THE TASKS OF EXECUTIVE AND ENGINEER

Turning to the first heading, the need for a broad, comprehensive view of the whole problem, it seems to me that

the inside viewpoint; the other, the outside viewpoint. Neither can do a complete job alone. The peculiar value to industry of the engineer who possesses training and experience comes largely from the fact that such an engineer can choose the most vital physical facts and bring them into such relation that they may be clearly and briefly expressed, and because the engineer's knowledge makes possible the discarding of useless statistics. The need for training and experience in the determining of what facts to collect and what lines to study can hardly be made too emphatic.

The problem, then, for the engineer, is to use his viewpoint, to use the scientific method undimmed by too much technique of the business, coöperatively with the executive in the collection and translation of the facts, to bring the essential factors from the cloud of nonessentials, and to define and express the clear-cut, sharp, comprehensive policies which should be pursued.

The problem for the executive is to aid the engineer by giving him the facts about the business, and by assisting him in determining the practicability of his suggestions. It must be remembered also that both executive and engineer must be open minded, if coöperation is to succeed. It is comparatively seldom that an engineer is asked to lay out a wholly new plant. He is generally doing the best he can with an old one.

One may often see in the records of many corporations the rings of age showing as many periods of growth as the rings around a giant sequoia. To determine the meaning and value of these different rings, to understand their translation, to find out what is orderly growth and what is disease excrecence, to determine what should be fostered, to devise means of loosening cramping bands which have grown up

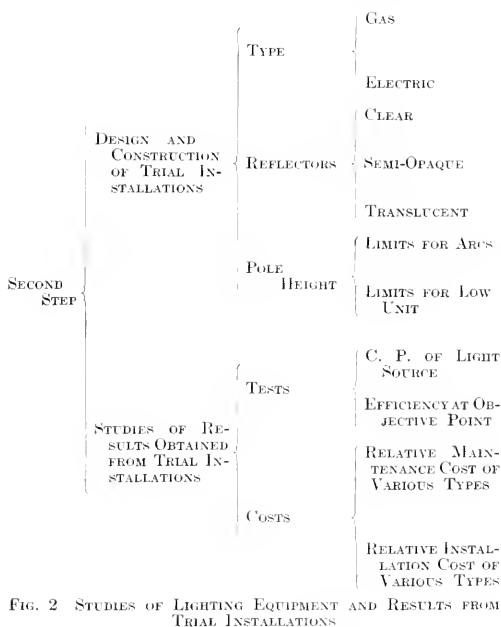

FIG. 2 STUDIES OF LIGHTING EQUIPMENT AND RESULTS FROM TRIAL INSTALLATIONS

around the business,—that task should be done best by the methods outlined here.

There is another reason why the obtaining of a broad comprehensive view is essentially a function of the outside engineer, even where the executive is himself an engineer. I personally believe that no man can get along without an outside view upon his problems, and that the executive is always dimmed by his nearness to the problem. I question whether any sincere man will deny that he has certain preferences for the work he is doing himself, or question that no matter how completely he endeavors to gain an unprejudiced view of his daily routine he is somewhat affected by a glamor of personality.

As I indicated before, the internal view is but one of the factors in the situation. No business lives alone. Not only within the business, but outside the business, any individual institution or corporation whose aims are clearly defined and rightly defended and expressed can remove to a large

degree any unpleasant relations with other corporations, with legislatures, with public service commissions, and with the public generally. Such questions as the following are constantly arising: What is the competitor's policy as compared with ours? What is being done in his field, and how does his field relate to ours? What will a legislature or a public service commission do that affects our future? What will the public reaction be upon a given policy? All uncertainty as regards the answers to these questions is largely cleared away when any branch of industry has a clearly set forth and definite policy, clearly expressed, and based upon proper study of the facts not only of its interior but of its exterior relations.

A BROAD COMPREHENSIVE STUDY

An illustration of a rather broad and comprehensive study made for an executive and a board, the results of a year's study of a problem, which included a survey of the whole field and a selection of those lines which seemed most profitable for investigation, is stated as follows:

Given a city with one hundred miles of streets and public places to be lighted and with a maximum population of a quarter of a million, provide the best light at the lowest cost.

In this investigation we first made a preliminary study, and laid out a work chart, Fig. 1, showing certain statistical and experimental studies that we desired to follow out. Under *space* we studied the geographical areas, and made a classification of the streets,—widths, pavements, nature of travel, and character of abutting buildings, taken from the highway plans of various streets, and arranged in groups. We then classified the street intersections and public places, found the areas, angles of intersecting streets, character of abutting buildings, particularly with regard to automobile travel and possibilities of bad lighting at the intersections. We determined the present condition in the case of the streets and intersections and public places.

We then studied the densities of population, and also studied with relation to these densities of population, the movement of building in the last five years and how the building had progressed in different periods and under different conditions in the city. As a matter of fact, the popular estimates of what building had occurred, were largely incorrect until we made this study, and the people of the city thought the facts about the city were quite different from what they actually were. We found that while the movement of building was supposed to be greatest in one direction, it was actually greater in another direction.

We then went on with the question of money, and studied the unit cost per street mile for the different classes of lighting for the different streets.

In regard to miscellaneous facts, we studied the location of existing lamps, from personal inspection, from official records, and from the contractors' records and comparing the city records with the contractors' records. The lighting had gone on as most lighting goes, in a varying manner; one year the appropriation had been large and there had been a lot of lamps put in as a result of new developments started. The next year the development died out, for some reason, and a lot of lamps had not been placed, and some of those which had been put in place were not effectively used. The result was that there was no regular distribution of lighting.

The heading "experimental studies" represents definite

experimental work. We put up adjustable standards similar to those used by the Edison Company, the Electrical Testing Laboratories, and by Mr. Lacombe in the New York City tests, and also similar to various other experimental plants elsewhere. Under "areas," we studied the illumination per unit area for different classes of streets and of street intersections. We studied the population and traffic census, especially with reference to foot traffic and automobiles, and incidentally let me say that in a similar study to this we found one interesting thing where we made a very considerable mistake, one which would have made much trouble if we had not been working coöperatively with the officers of the city, and had not invited them to criticize freely our studies. We took the traffic census on a given road and found there were only eighteen vehicles going up that road. We checked it up, and one of the persons familiar with the situation said, "There is a big mistake there, because that is where the early morning trucking goes." We went back and made the study between two and six o'clock in the morning and found over a hundred trucks coming in over that road, which went out late in the afternoon. In the late

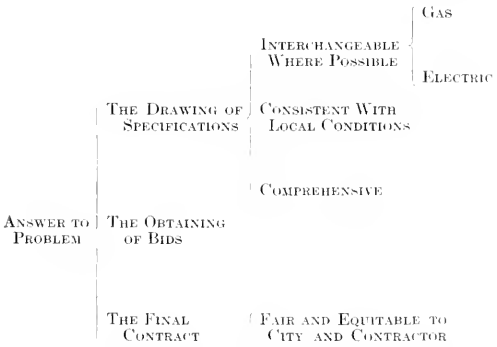

FIG. 3 CHART INDICATING ANSWER TO THE PROBLEM

morning, when the study was taken, there was almost no traffic on that street. There is an illustration of the necessity of coöperating with the people in the place, to find out what the facts are about the actual conditions. If we had not checked that study street by street with the people who knew the conditions, we should have based our lighting for that road on the morning study, and found no traffic worthy of mention. Under "intensity of light and light sources," we determined the unit intensity per unit population per unit area, and in getting that together there is only one conception, practically, that one should give the executive to use, and that is the conception of the unit, the concept of the candle, because after all our light unit comes back (with full recognition of the carefully drawn and admirable work of the Bureau of Standards), to a concept of a candle, just as density of population or unit population goes back to the conception of one man in one house, and that unit concept can always be given simply and directly. Almost the only thing used in the preliminary work, which needed any translation, was the word "unit," (and we only used that because we had to use the unit concept) and we found that was easily translated, even with the men on the street.

We then took up the question of design and construction of trial installations for both gas and electric lamps, Fig. 2. In the case of reflectors, we studied the clear, semi-opaque, and translucent. We also studied the matter of pole heights, limits for arcs, and limits for low units. We made studies of results obtained from trial installations, and made tests to discover the candlepower of light sources and their efficiency at given points. In considering the cost of this installation, we then proceeded to a study of the relative maintenance and costs of various types. The answer to the problem was the final drawing up of specifications, Fig. 3, making the gas and electric units in-

FIG. 4 STUDENT ENROLLMENT FOR FIVE YEARS

terchangeable where possible, and making specifications consistent with the local conditions which did not require tests of an expensive nature to be carried on, and which would be comprehensive. It is impossible in any chart to show all of the different factors which concern specifications in general. Perhaps there is no more dangerous fallacy than the concept that a specification which can be used with great satisfaction in one plan can be used with equal satisfaction in another. The main thing which we desired to obtain was a final contract which should be fair and equitable to both the city and the contractor. Such a study as I have shown here is a brief representation of my first concept which concerned the possibilities of engineering work done coöperatively with an executive in obtaining broad, comprehensive views for the education of associates, for the public, and for the authorities. A SELECTIVE STUDY The second division of my subject concerns the application of the theory of selection to the different parts of a

problem in such a way as to enable any executive to understand those factors in a business which are more valuable and those which are less valuable. Certainly if there is a branch of engineering which, from the standpoint of money returns, needs most to be applied to industry, it is such studies as shall give readily to the executive and to legislative bodies and corporations that concept of the selective values of their business. There is no way I know by which this can be obtained save through engineering studies of the type illustrated here;—for there are very few businesses which are so simplified that one can tell offhand at a glance what line will pay and what line will not. Such

mirable schools were added to the Institute, and since one of my tasks, when I went to the Institute, was to determine which of those schools were worth while, which should be selected to remain, and which could properly be dropped, I recognized that I must make for myself such a study of selective values as I am outlining here. Among our other departments we had a Library School which in many ways had done admirable work; this was studied among others.

The first thing concerning the Library School that we studied was the curve of students for five years, from 1908 to 1913 (Fig. 4). And as regards the period to be studied, it should be noted here that nowhere else do training and experience as the part of the engineer count more. The analysis of periods which are too long or too short may easily prove not only wasteful but actually misleading. The second problem came in connection with library salaries, tuition, and the disbursements. We found that the library salaries rose considerably, and the disbursements remained about even, while the tuitions fell off materially (Fig. 5).

The total registration of the Institute was 13,201 for five years. Our Library School registration was 95, or 0.7 per cent. The total number of graduates for thirty years' existence of the school was 317. We then studied a comparison

studies as those concerned with the possibilities of obtaining raw material, of development of transportation, of the labor market, and of selling fields,—all come into this group and concern such comparative information as shall make selection between different problems possible. Such comparative information as will enable the executive to know which part of the business will be mainly effective, provides the means by which the executive may select what shall be pushed and what shall be held, what shall be dropped, and what shall be left for a future time or for future stimulation. It is upon such selective decisions that again and again large decisions may hinge.

I had made a number of studies of this nature when I went to the Drexel Institute as president, and found there a number of departments which had grown in the same way that most of the departments of the small college grow. There was a period in American life when the small college endeavored to be a university without success. That period is, fortunately, passing, and we are coming to realize that there is a definite place for the small college and a definite place for the university. During that period a number of ad-

of the total expense of the Drexel Institute and expense of the Library School for five years. The total Library School expense was 2.8 per cent of the total Institute expense (Fig. 6).

We then took up the question of the employment field for the graduate of the Library School. We found in comparing the number of positions and salaries in a selected group of Philadelphia libraries, that there are one hundred and twenty holding positions in selected libraries, drawing from \$216 to \$600 per annum; thirty-one drawing from \$600 to \$720 per annum; twenty-seven drawing \$900 per annum; and twelve drawing over \$900. In five years all the general libraries in Philadelphia took direct from the Library School seven graduates. Total notices on file of vacancies in libraries of the United States for the past five years at salaries of \$600 and over, were one hundred and sixty-six (Fig. 7). It should be remembered, of course, that this employment field is for young women graduates, but it must be equally remembered that this is the record for five years. On the basis of the facts shown above, the board decided that the Library School should be given up.

This method is applicable to any business. I have no question that by varying the means of treatment with the necessities of the case, you can determine, to a considerable degree of accuracy, what is right to keep and what is right to eliminate. The educational example used here is chosen as an illustration.

I have already spoken of the question of the time-saving factor in the preparation of reports. The average director or trustee is a busy man. The meetings of the boards of directors or trustees which I have attended in different parts of the country have almost always been brief, a condition which calls for such rapidity and such pointedness of statement, as shall bring conviction to the eye as well as to the ear, and will make possible wise legislative action upon the part of the board. If the proper ends are to be obtained, clarity as well as brevity is essential.

Since 1906, I have been largely interested in the study of engineering reports from the standpoint of clearness. The inadequacy, diffuseness, and obscurity of many of these reports is remarkable. Reports to be read by laymen are either couched in technical language difficult of comprehension

sion, or so much material is laid before the public that they are commonly unable to come to the final, sharp, clear understanding of what is meant, and such lack of expression is a great handicap to our profession.

A STUDY IN CLARITY

Fig. 8 shows the summing up of the results accomplished through a study of the type outlined above and through construction on the basis of the study, and illustrates the principle of clarity which it is desired to show.

The results concern the regular delivery of thousands of papers called for daily on the requisitions of clerks. No mention is made of the emergency system of delivery which was constructed in order to care for all such requisitions. The problem here so far as the regular delivery from the file room is concerned resolved itself into four phases:

a Diminishing of the time required to fill requisitions. The work done reduced the time in question from five to three hours according to the records made.

b Regularity of delivery. The installation of a controlled system of transportation replaced irregularity of delivery with controlled and inspected regularity.

c Reduction of irregular messenger service carried on by department clerks. This irregular service was abolished and the whole messenger service carried on by the two boys who had previously done but a part.

d Completeness of delivery. This was provided and assured by a complete system of inspection. The entire differences in service noted here was accomplished without increase of working force but actually with a decrease.

A STUDY IN BREVITY

Brevity is also essential in an engineering report. It is necessary to attack the problem in such a way as to give

definite and complete information to a limited, definite and complete group. The engineering report is a translation of physical facts to be used in many cases for the information of groups. The group of people for whom that report is written should be considered quite as much in an engineering report as in any other translation of physical facts on paper.

To come to a specific case in Fig. 9, I have constantly found that the question of prices was one of the most difficult things to go into in a short space. I have spent a considerable amount of time in endeavoring to get all price facts about several businesses on a single sheet of paper. The facts were on 34 pages of catalogue when I went to the Drexel Institute, and one would have to read over 34 pages of this catalogue to get all the facts about the different fees and different items of cost information one would naturally desire. To solve this problem we standardized on tees, and put them all into a single place, and for the sake of clarity stated in all cases three things, the amount, what the student obtained for the amount, and when it was

payable. These are the three questions that are always asked by prospective students and their parents.

REQUIREMENTS OF AN ENGINEER WORKING IN THIS FIELD

There is no question that there is some opposition to any question of engineering study, or especially of any engineering investigation. Most of the present justified feeling against the very word *investigation* has come because of the defects of the investigator. Much of that opposition has come because it was assumed that the engineer was working to investigate or find fault with somebody, instead of work-

- c To check his work with the practical needs and limitations of the business, keeping an open and perceptive mind.
- d To change his methods for the better with the advance of the engineering and industrial art—in short to keep abreast of the “best of the art.”
- e To have a wide acquaintance with those men of his profession and of other professions and callings, who know most of special lines of which he may need to know.
- f To bring the best that science and industry has yet produced to bear upon the problem before him.

Those are serious requirements to lay down. Yet there is no small number of engineers who I know could meet them all. They can hardly be made materially less, for in work like this the danger of construction turning to destruction in untrained hands, presenting ill digested, wrongly collected, wrongly translated, and wrongly expressed facts, is too great to be readily assumed.

FACTS VERSUS THEORY.

There is another matter which affects very considerably, as I said at first, any problem in engineering investigation, and any problem of expression of engineering facts, and that is the fact that people to-day are looking, it seems to me, for facts properly expressed rather than for legal cases. Again and again in this country we have suffered from one case placed against another, one theory placed against another theory; and I believe that the period is coming more and more when the facts are going to settle problems; but facts alone are not enough. It is only when facts are expressed in such a fashion as to reach the definite audience which it is to reach that facts really gain the day.

On this whole question, it would seem to me that it is of vital importance to the profession to show the industries and institutions of this country the value of such engineering service as I have outlined here, and perhaps also the need to have engineers with training, experience, and the power of expression carry on this work. I have endeavored to express here in concrete form a method of procedure which has been followed by several of my friends, and by myself, in recent years. In my own case, I have been working consciously along this line for the past eight years, during which time I have been concerned with a number of studies of institutions, corporations, and businesses. In each of these, I have endeavored to make of the study a logical whole which should be practical, selective, simple, brief, effective, and properly expressed.

In conclusion, I believe that work of this type offers a great field for the trained and experienced consulting engineer, and that industry in the next few years will realize the need of the consulting engineer as never before. We have for a very long time had to do with the consulting lawyer. I believe the executive of the near future is to be more and more ambidextrous in his counsel, having his lawyer on one hand and his consulting engineer upon the other. We must obey the laws of man, but it is even more necessary to obey the laws of nature, and the consulting engineer is as much needed by the executive, to aid him in the determination and expression of the facts, as his counsel is to tell him what his legal rights are and in what way he can lawfully carry on his work.

ing cooperatively with the men in the business to do the most that could be done for the business. Moreover, to make savings of money, service, and time, the cooperative engineering adviser to an executive must be able—

- a To distinguish clearly between records which are vital to the future policies of a business and those which are merely historical. The past in industry as a determinant for policies is of value only as it is vitally concerned with the future.
- b To omit many engineering refinements, that cost much money and lead to a “false and delusive accuracy,” as one of my old instructors used to put it; to avoid, so far as possible, in all cases doing work that “costs more than it is worth.”

FOREIGN REVIEW AND REVIEW OF THE PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

EFFECT OF THE WAR ON FOREIGN PERIODICALS

As has been before pointed out, the events in Europe have seriously affected the amount of engineering material published in the current foreign periodicals. Some of the publications have been entirely discontinued for the present; the others, and among them the leading engineering magazines, have cut down the amount of space in each issue. Then again, many appropriations for research in engineering schools and works of manufacturing companies have been cut down for various reasons, while—and this is the most unfortunate feature of the entire situation—thousands of engineers have been diverted from their regular work to military duties through which many of them have already lost their lives. A vigorous effort is being made, however, to maintain the Foreign Review section of the Engineering Survey at its usual standard.

THIS MONTH'S ARTICLES

In the present issue an article discussing the use of liquid air as an explosive, chiefly for mining and constructional purposes, is abstracted. Its most important features appear to be comparative safety, especially in the case of misfires, and the possibility of manufacturing it in any country where there is a source of power. In the same section is described a new type of two-stage single cylinder compressor of apparently simple and rugged construction.

The "Uto" two-stroke cycle engine, built by a Swiss concern, seems to be also of a very simple design. In addition to that, it has an interesting system of water cooling without water injection into the interior of the cylinder. It has also an interesting and novel form of packing about the main bearings. Some data of tests of the engine operated with crude oil are reported.

The question as to whether ammonia explosions do actually occur in refrigerating plants is carefully considered in a report of an article by G. Cattaneo.

A system of oil separation from water of condensation with particular reference to large power plants and mining plants is described by Mr. Vahle.

From a German periodical is briefly abstracted an article on fireless locomotives, in which, among other things, is contained the statement that such a locomotive used 2½ years fairly continuously in the works of a machine company, cost less than \$12.50 in repairs for the entire period.

The present scarcity of copper in Germany called attention to the possibilities of the use of wrought iron in locomotive fire boxes and G. Hammer shows that such a use is also favored by the present conditions of railroad operation and train handling.

The Mellen rod casting machine is described in a paper before the American Institute of Mining Engineers.

The journal of the American Society of Heating and Ventilating Engineers appeared in April in a new form. An article on the measurement of air flow, of considerable interest, is briefly abstracted from it.

From the Memoirs of the College of Engineering, Kyoto

Imperial University, is taken an abstract of the main data of tests on the combined bending and torsional strength of cast iron.

Very interesting data of tests on a recent type of chain grate stoker and new methods of baffling Stirling boilers are reported from a paper before the Engineers Society of Western Pennsylvania. From this paper, it appears that a material gain in efficiency is obtained by the use of what the author called the "slow chain" method of firing.

The lateral friction of winding ropes and the magnitude of the angle of maximum friction are discussed in a paper before the Institution of Mining Engineers (London).

Several papers are abstracted from the transactions of the North-East Coast Institution of Engineers and Shipbuilders, such as tests on a Diesel engine in which were used with considerable satisfaction rotary indicator diagrams, and results of substantial interest which have been obtained. The influence of various temperatures on the properties of Admiralty gun metal are discussed by Professors A. Campion and John G. Longbottom, who reported several phenomena bearing on the structure of metals. An interesting paper on the strength of welds made by the acetylene process was presented before the same organization by Professor Campion and W. C. Gray, in which it is again shown that oxy-acetylene welds are not as strong and are less reliable than the unwelded portion of the metal. It was also shown that hammering, while increasing the fatigue resisting properties of the material, may also be productive of brittleness, and that reheating and annealing alone appear to be of little value so far as increasing the fatigue resistance in the welded portion is concerned. Further, that the thicker the plate the less reliable is the weld and the greater the reduction in strength.

From the Journal of the Western Society of Engineers are abstracted two papers, one on the electrification of steam railroads and another (really two papers on the same subject) on wind stress in the frames of office buildings. Particular attention is called to this latter.

FOREIGN REVIEW

Air Engineering

LIQUID AIR AS AN EXPLOSIVE, M. Przyborski

Data on the use of liquid air as an explosive, in particular on the Kowatsch system.

Professor Linde appears to have been the first to introduce successfully an explosive consisting of ground charcoal and liquid air. Since then, Claude and d'Arsonval, in France, have further developed these processes and finally Kowatsch and Baldus, in Germany, have lately worked it out still more fully, partly under the pressure of the present demand for an explosive of exclusively German manufacture.

In order to avoid excessively rapid evaporation of the liquid air, Kowatsch, who uses a cardboard cartridge, introduces first a cartridge with dry carbon into the drill hole separately and without any liquid air, which is put in only just previous to ignition. This process permits reduc-

ing to a minimum the period of evaporation, and also increases the factor of safety of operation.

The cardboard cartridge contains a perforated pipe in which there is a mixture of infusorial earth with oil and asphaltum or lamp black and paraffin, neither of which is explosive in itself. This center pipe contains another cardboard tube over which a third cardboard tube is set, serving as an exhaust pipe for the products of evaporation of liquid air. If several drill holes have to be exploded simultaneously, the electric connections are made accordingly.

The liquid air which has to be used for each hole is kept in a precisely determined quantity in a small bottle, the opening of which is provided with a metal tube and conical nozzle, connected with the central tube of the cartridge. To load the cartridge, all that is necessary is to lift the rear end of the bottle. The liquid air is raised by the pressure of its own products of evaporation and gradually passes into the cartridge. At the instant when the charge is ignited by the

Maschinenbau-Aktiengesellschaft Marktredwitz, vorm. Heinrich Rockstroh in Marktredwitz, Bavaria, Germany) described in this article, strikes one as being of very compact design and substantial construction. It is designed in such a manner that it rests on a foundation throughout its length, which tends to eliminate vibration; further, the suction and compression valves on the low pressure side are located on the cover of the low-pressure cylinder which is designed as a valve chamber.

The atmospheric air, after having undergone preliminary compression in the first stage, passes through the compression valve on the low-pressure cylinder cover into an intermediary cooler. Then, through the suction valves of the high pressure stage, it reaches the annular space of the stepped piston, of which the differential area (see Fig. 1A) forms the high pressure cylinder, and here the air undergoes a second stage of compression. As soon as the desired first stage of compression is effected, the compressed air is

FIG. 1 TWO-STAGE SINGLE CYLINDER COMPRESSOR

electric spark, the liquid air combines with the charge and there follows an explosion of exceptional violence.

Among the advantages of this method of explosion is the fact that, in the first instance, the materials used are not explosive in themselves and the explosive mixture is formed only at the very last moment in the bore hole itself. In the second place, should an explosion be missed, the liquid air will evaporate and the remaining cartridge is perfectly harmless. (*Verwendung von flüssiger Luft als Sprengmittel nach einem neueren Verfahren*, M. Przyborski. *Zeits. für Eis- und Kälte-Industrie*, vol. 7, no. 9, p. 93, March 1915, 2 pp. d).

A TWO-STAGE SINGLE CYLINDER COMPRESSOR

Notwithstanding the fact that there are a number of two-stage single cylinder compressors on the market of really good efficiency, new types continue to be introduced and adopted in practice. The author ascribes this to the fact that the two-stage single cylinder compressors introduced so far all suffer from excessive space demand per unit of output and insufficient accessibility.

From this point of view the new compressor (built by

transferred by the pressure valve to the high pressure side.

The piston (Fig. B) is made of gray cast iron. As a two-stage piston, it carries, on both the high pressure and low pressure side, self-tightening packing rings made of alloy cast iron. The pin is set inside the piston and has an extremely hard surface with a soft core which is of considerable advantage from the point of view of wear and mechanical strength. The connecting rod is made of steel and is provided at one end with an adjustable brass bearing for the pin and at the crank pin end with a so-called marine head, the brasses of which are filled with white metal. The shaft is cranked and sits in annular lubricated bearings with white metal bushings. In small compressors, these bearings are made in two parts and equipped with a loose ring. In large units, they are in four parts and equipped with ring lubrication, with self-adjusting rings.

The air is cooled by water, the valve chamber being cooled as well as the working cylinder, and in the intermediary cooler, water cooling is also used. The cooling water passes through the pipes around which moves in countercurrent the air to be cooled, baffles being provided to force the air to move in an indirect path around the pipes.

Fig. C shows the arrangement of the valve gear. Since the flowing air can produce only quite a small pressure on the valve discs, it has been found possible to limit the motion of the valves to the utmost, as a result of which the valve lift could be also maintained quite small. On the other hand, in order to provide a sufficient cross section of flow, ring valves had to be used. Each ring is held against its seat by a spring and the spring (2, Fig. C) is so adjusted that the movement of the valve corresponds exactly to that of the piston. Since the speed of the piston compressor driven by a belt cannot be closely regulated in the present design, the amount of air sucked in is regulated by a separate valve gear, which permits the unloading of the compressor when the air tank is full. If the demand for air increases, the compressor is automatically placed on load again. One design of such a valve gear is shown in Fig. D. It is automatic

1914. The present abstract is devoted to the description of the two-cycle "Uto" engine built by the Iron Foundry M. Koch, Zurich, Switzerland.

This engine, built in 4, 10 and 24 h.p. units, appears to be of very simple design. The compression of the scavenging air is effected in the crank case, from which the air flows through slots in the piston and jacket onto the upper end of the cylinder and in this way drives out the residues of combustion through the exhaust ports. The grid valve which admits the air into the crank case has spring steel plates of rectangular cross-section.

The cylinder cover shown in a simplified sketch in Fig. 2A, is semi-spherical designed like a charge cover, but does not have to be maintained in a glowing state in order to cause self-ignition of the charge. In its upper part, the cover is provided with water cooling which protects the material from overheating. This water enters by pipe *L* into the chamber *E*, falling directly on the fuel nozzle *D* and in this way keeps it cool. The water flowing out of *J* is led to the exhaust funnel *K*, designed like an injector. The major part of the cooling water in the cylinder jacket passes through the nozzle into the outflow in order to operate the

FIG. 2 "UTO" TWO-STROKE CYCLE ENGINE

and regulates the air admission by means of a cut-off. As soon as the pressure in the air tank exceeds a certain maximum, the apparatus lifts the suction valve and permits the air taken in to return into the section chamber. When the pressure in the air tank goes down, the suction valve is again released. There is provided a special device, however, to regulate the compressor by hand. In addition to this, further regulation is secured by equipping the flywheel with an electro-magnetic coupling; when the tank is full, the compressor is automatically set at rest while the flywheel is allowed to run.

The original article contains a table showing the efficiencies, outputs and approximate dimensions of the present machine. (*Ein neuer zweistufiger Einzylinder-Kompressor, Der praktische Maschinen-Konstrukteur*, vol. 48, no. 13/14, p. 61, April 8, 1915, 3 pp., 6 figs. d.)

Internal Combustion Engineering

"UTO" TWO-STROKE CYCLE ENGINE

A continuation of an article describing internal combustion motors at the Swiss National Exposition in Bern, in

injector, while the rest of it, because of the suction produced at *J* by the injector, is lifted into the chamber *E* by the pipe *L*. This peculiar method of cooling (and with it the time of ignition) can be regulated, in accordance with the load, by the cock *G*. Of special interest in this connection is the fact that no water is injected into the interior of the cylinder. The fuel oil pump *B* is regulated by a shaft governor which varies the stroke.

In order to make the main bearing fully accessible, the crank space is provided with a patent method of packing (Fig. B) in which a lower membrane is alternately pressed slightly against first one and then the other side of a circular groove. This arrangement permits the equipping of the bearings with ring lubrication and at the same time makes the cover removable.

The author carried out on such a motor a series of brake tests in which he used crude oil of specific gravity 0.87 and obtained the following values:

Rev. per min.....	305	306	307
Effective brake output, h.p....	24.9	17.25	12.35
Fuel per effective h.p.h., g lb.242	1532	248	545
		273	600

(*Die Verbrennungsmotoren in der Gruppe 32 an der Schweiz. Landesausstellung Bern 1914*, Professor P. Oster-tag, *Schweizerische Bauzeitung*, vol. 65, no. 15, p. 165, April 10, 1915, 2 pp., 3 figs., article not finished, d.)

Railway Engineering

FIRELESS LOCOMOTIVES

The advantages of the fireless locomotive lie in its unquestionable safety with respect to fire, which makes it extremely convenient for use in factories handling explosive materials and in gas works, as well as in various classes of chemical manufactories. The attendance is extremely simple because of the absence of the usual boiler, with its attendant necessity of watching the fire and water level. Also, since the pressure in the steam container cannot exceed a certain definite amount, it is not necessary to watch constantly the gage and one man can very well take care of even a large fireless locomotive, devoting practically his entire attention to the road. The water container of the fireless locomotive is almost free from scale and the repairs must be very low because of the absence of all the most sensitive parts of an ordinary locomotive boiler, such as the fire box, staybolts, fire tubes, etc.

A fireless locomotive which has been used for 2½ years in the works of the Hannover Machine Company cost only 50 marks (\$12.50) in repairs in that period, during which time it was used not only in the plant itself for switching work, but was also several times loaned to other works in the neighborhood. It is considered that a depreciation of 7 to 8 per cent per year is entirely sufficient because of its long life. It has, of course, its disadvantages, and can be used neither for trunk line service, as the author shows by detailed calculation, nor for the handling of heavy loads. Its field is apparently in switching service and hauling loads inside the factory limits.

The article gives in detail the calculation of the water tank as a heat reservoir. A brief bibliography is appended (*Feuerlose Lokomotiven*, G., *Rauch und Staub*, vol. 5, no. 5, p. 73, February 1915, 10 pp., 11 figs. (dp)).

WROUGHT IRON IN LOCOMOTIVE FIREBOXES, G. Hammer

Discussion of the application of wrought iron in the manufacture of locomotive fireboxes.

Up to the time of the present war, railroads in Germany were very large consumers of copper. A very large amount of secondary equipment, such as door handles, hand rods, etc., as well as all brasses, were made of copper alloys, while fireboxes, staybolts and locomotive tubes were made of pure copper. This was due to the fact that experiments with the introduction of wrought iron fireboxes did not turn out satisfactorily some years ago, and it was there found that although the first cost of installation of a copper firebox was several times that of the iron firebox, it paid in the end. In the first instance, because the depreciation of the copper was quite insignificant and the remelted firebox returned practically the original value in metal. In addition to that, copper is easily worked, does not rust, is little subject to burning and easily permits the tightening of joints and staybolts.

Of late, however, even in Germany, several circumstances tended to equalize this relation in favor of the wrought iron firebox. The main fact was the rapid increase in size and

operating pressures of modern locomotives. This led to a considerable reduction in the life of a copper firebox, first because the great increase in temperature materially reduces the strength of copper and next because its coefficient of expansion is greater than that of iron, so that, in the long fireboxes, there is a greater tendency towards bending, and consequently greater frequency of ruptures.

The conditions of locomotive operation have also changed in favor of the iron firebox which is particularly liable to suffer from rapid and sudden cooling; locomotives are now worked on two and three shift schedules and therefore they are less time out of service. Further, they are now nearly always washed with hot water, which affords better protection than washing with cold water.

The author believes, therefore, that there is a good chance for the introduction of wrought iron fireboxes on locomotives in Germany. (*Ueber die Verwendung von Flusseisen zu Lokomotivfeuerboxen*, Gustav Hammer, *Glasers Annalen für Gewerbe und Bauwesen*, vol. 76, no. 907, p. 129, April 1, 1915, 2 pp., g.)

Refrigeration Engineering

AMMONIA EXPLOSIONS IN REFRIGERATING PLANTS

The author discusses the question as to whether ammonia explosions do actually occur in refrigerating plants.

In particular, he refers to a case of an explosion in a German refrigerating plant, which was ascribed to the decomposition of ammonia in the compressor cylinder and the penetration of the gases into the engine room. This case led to the investigation by the Institute of Physical Chemistry and Electro-chemistry of the Technical High School at Karlsruhe, by S. Schlunberger and W. Piotrowski, who introduced into a bell-shaped glass vessel, 110 mm. (4.33 in.) in diameter, mixtures of ammonia and air in various proportions and ignited them by an electric spark. It was found that a mixture of air with from 16.5 to 26.8 per cent by volume of ammonia violently exploded in the glass vessel, but that with the ammonia content above or below these limits, no explosion took place. Comparative tests with a tube-shaped vessel have given a slower combustion, due probably to the cooling action of the walls, the region of explosibility being limited to from 19 to 25 per cent by volume.

Refrigerating engineers are, however, interested principally in the question whether conditions such as have been shown by this experiment, and which produce explosibility of ammonia and air mixtures, can actually occur in practice. It is hardly likely that under ordinary conditions, 16 to 20 per cent by volume of ammonia can mix with the air, but that may, of course, occur in exceptional cases, for example, when a defect develops in the operation of the machinery, a rupture of a pipe occurs, or something like that. In the case referred to above, a branch pipe broke and allowed ammonia to flow out. The fireman, who was burned about the face and hands, claims that he heard an explosion and saw a flame. As there was a gas burner in the engine room, the assumption naturally was that an explosive mixture of ammonia and air took fire from the open flame.

However, the author doubts this, because the conditions under which the actual explosion occurred did not coincide with the conditions which were present when the tests were carried out. In the latter case, ignition was caused by an electric spark, and, because of the shape of the vessel, prop-

agated with considerable velocity. It is by no means proved that an ignition could likewise occur from an open gas flame and that the combustion in free air would occur in the same manner as in a closed experimental bomb. As a matter of fact, the author doubts that there was any explosion at all in this case, in the sense of a sudden combustion of a mixture of gases, and he supports his contention by reference to another accident where ignition of ammonia by a gas flame appears to be fairly well established. According to a report of the German Slaughterhouse Paper (*Deutsche Schlacht- und Viehhofzeitung*, November 15, 1914, p. 574), in November, 1914, there occurred in the engine and boiler room of the Municipal Slaughterhouse, at Elbing, a fire due to a rupture on a compressor and ignition of the escaping ammonia by an open gas lamp. It appears that in this case a screw on the compressor piston worked loose and fell between the piston and cylinder cover so that during the return stroke of the piston the cover was fractured. No explosion occurred, but there was a strong fire, which destroyed the roof of the house.

Mr. A. Behr, in a Report to the Sixteenth Annual Meeting of the Association of German Inspection Engineers (*Verhandlungen der 16. Hauptversammlung des Vereins Deutscher Revisions-Ingenieure*), read a paper on the "Decomposition of Ammonia in Ice Machines," where he mentions a grave accident in the brewery of the Hildesheim Brewery Company, in which case an ammonia compressor was started with the exit valve in the pressure piping closed. As a result, the cylinder was brown up by the increasing pressure. Immediately thereafter, the entire engine room, which was lighted by gas, was enveloped in a sheet of flame. In another case, in a Berlin brewery, rapid ignition took place when a fire was brought near an open ammonia compressor. According to the opinion of Mr. Behr, this accident was due not to the combustion of ammonia and air mixture, but to the ignition of hydrogen which formed in the engine through the decomposition of ammonia, which decomposition, in its turn, was due to rise of pressure and temperature of ammonia caused by starting the compressor with a closed pressure valve.

That this decomposition does take place was shown by the experiments of Doctor Mohr, who has found in three instances a high content of free hydrogen and nitrogen in experimental compressors. For practical purposes it would be desirable to carry out a theoretical and experimental investigation which would show whether decomposition of ammonia actually takes place, and if so, how it can be prevented. (*Zur Frage der Ammoniakexplosionen*, G. Cattaneo, *Zeits. für die gesamte Kälte-Industrie*, vol. 22, no. 1, p. 3, January 1915, 2 pp., *pe*).

Steam Engineering

OIL SEPARATION FROM WATER OF CONDENSATION

The article describes a method of separating oil from water of condensation, such as is applied in Germany in mine plants and large engine houses.

Where there is a large number of engines, the author recommends leading the water of condensation to some deep well (Figs. 3A and B), arranged in such a manner that it is divided by the walls *d* into three large compartments, *a*, *b* and *c*. Into one of these compartments the water of condensation, rich in oil, is allowed to flow, and is then led

through the several pipes *e* from the deepest part of the well into the second compartment, whence it passes into the third compartment, and is finally delivered to where it belongs by the centrifugal pump *f*, having its suction point at the deepest part of the well.

Since the water of condensation is still so hot that it cannot be taken up by the pump with a high suction head, the pump is located in the shaft *g* close to the collector well in such a manner that it is below the water level of the third compartment. In order that the third compartment would not be drained if its inflow should happen to be lower than the delivery of the pump, there is provided in the suction piping a throttle valve *h*, with float *i*, maintaining the water level in that section always at the same height. The third section is further provided with an outflow port *k* (leading into the sewers), the purpose of which is to prevent the well from being flooded in case of the pump stalling, or of

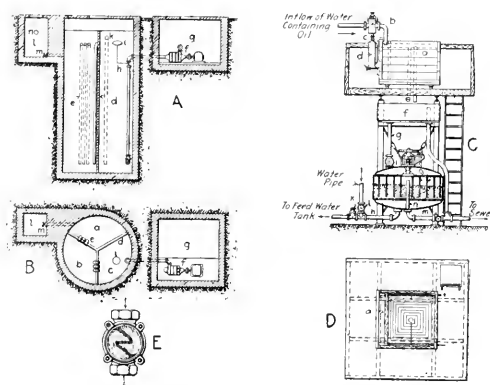

FIG. 3. PLANT FOR SEPARATION OF OIL FROM WATER OF CONDENSATION

excessive influx of water. This outflow is located at a point much higher than the suction piping, and is connected by a pipe with the bottom of the well, so that all outflow water should be as free from oil as possible. To permit of the cutting out of the entire plant for purposes of cleaning or repairs, the water of condensation, rich in oil, coming from the various sources, is led into a small collector well *l*, located in front of the first section; this well may be cut off from the first section of the tripartite well by means of a valve *m*. When this valve is closed, the water is discharged directly into the sewer pipe by an exit port *n*, located at the higher level.

When the water of condensation is admitted to the well, the oil in it is in a state of either drops or emulsion. In the well, when the water is in a state of rest, the oil in drops separates because of the different specific gravity, and can be easily collected on the surface of the water. This oil is pure because of the heavier impurities having settled down to the bottom of the well, and can, therefore, be again used for cylinder lubrication. If, however, the water of condensation is intended for use as boiler feed water, it must be freed also from the oil in the state of emulsion, and this can be done electrolytically, for example, by means of the apparatus shown in Figs. C and D (Renbold electrolytic oil separator).

to the speed at which the machine is operated. If for any reason the machine should stop, the flow of metal would also be automatically shut off. If any foreign material clogs the chain, a safety pin is thrown to protect the mechanism from injury. The rods are delivered from the machine immediately to the die of a bull block, which turns them down to suit particular orders. The advantages of the machine are simplification of manufacture, elimination of loss from oxide scaling during the heating and rolling, and elimination of danger to human life—the latter because the apparatus is completely enclosed and the operator is protected from injury.

The article describes also a continuous casting machine for making rods of lead and soft metal alloys $\frac{1}{4}$ in. and upward in diameter. The author states that the machine's operating cost is less than 30 cents per ton of molten metal cast into the form of rods (7 pp., 4 figs. d).

Measurement of Air Flow, Arthur K. Ohmes (abstracted)
Pipe System for Water Heating, Professor F. E. Giesecke
Apparatus for the Study of Heat Radiation, Professor J. D. Hoffman

MEASUREMENT OF AIR FLOW, Arthur K. Ohmes

Description of various apparatus used for the measurement of air flow. Discussion of their advantages and disadvantages and field of application.

The author divides all instruments for the measuring of the flow of air into seven classes, which he considers preferable to the division into so-called volumetric and pressure measuring instruments because of the intimate relation existing on some instruments between volumetric and pressure conditions.

The precision of measurements in heating and ventilating has notably increased during the last two decades. Fifteen years ago engineers were satisfied to be able to read a column of water accurately within one-tenth of an inch. Five years ago, one-hundredth of an inch was considered an accomplishment; while today instruments are available with which one-thousandth of an inch of water can be measured. The same applies to air measurements. Ten years ago, measuring an air current at a velocity as low as 1 ft. per second was approximately the limit, whereas today a current of air of less than one-tenth of a foot per second can be measured with fair accuracy. The author believes, however, that the limit of exactness in this field of measurement has by no means been reached.

Various types of meters, anemometers, Pitot tubes and devices for measurement by adding heat to the air are described, as well as long distance and centralized air measurement gages, and the micromanometer. These descriptions are not suitable for abstracting. The common fly-wheel anemometer is not suitable for air velocities below 2 ft. per second because the work done by the air to overcome friction is, at low velocities, lost for measuring the air current itself. If, however, the frictional losses in measuring air current are compensated for (as in the apparatus described by the author), an anemometer can be used for the lowest air velocities.

As regards Pitot tubes, the author believes that the ulti-

mate Pitot tube that should be accepted as a standard the world over need not be one with a correction factor of unity (like the Prandtl tube), and may have any, or even a large, correction factor, if constant, for any and all velocities, provided the slight deflections of the tube will not vary the results for velocity and static pressures. He believes, however, that except when both great accuracy and integrity prevail in making the test (as in laboratory or small apparatus factory tests), it is difficult to expect much consistency in air measurements with Pitot tubes. The author strongly insists that in any case, in order to secure uniform results, the most accurate instruments are necessary, and that the greatest care and integrity of purpose is required. (23 pp., 26 figs. d).

Tests on the Combined Bending and Torsional Strength of Cast Iron, Tsuruzo Matsumura and Genjiro Hamabe (abstract)

Beiträge zur Theorie der Elastizität gekrümmter stabförmiger Körper, Tsuruzo Matsumura.

TESTS ON THE COMBINED BENDING AND TORSIONAL STRENGTH OF CAST IRON. Tsuruzo Matsumura and Genjiro Hamabe

The paper investigates the elastic behavior of cast iron under combined bending and torsional stresses.

Recent experiments on elastic failure of mild and harder steels show results not in close conformity with the principal stress theory of Rankin or the principal stress theory of St. Venant. They rather support the hypothesis proposed by Mohr in 1900, which may be stated as follows: "Elastic failure of ductile material or the breaking of a brittle material takes place when the shearing stress, acting at the point along a certain plane, attains a limiting value which is a function of the normal stress at that point." As regards the combined strength of a brittle material like cast iron, little is known, which was the incentive for the experiments carried out by the writers.

The testing machine was designed in conformance with the principle of Croker's testing machine. The test piece was made of the form and dimensions shown in Fig. 5A. The diameter d was taken as $\frac{11}{16}$ in. for ordinary cast iron and $\frac{5}{8}$ in. for high grade cast iron. All the test pieces in a single series of tests were cast in one charge. Fig. B shows the method of molding for Series 1 and 2 and Fig. C, that for Series 3 and 4. In the tests, the writers determined the bending moment and torsional moment for various pieces, calculated the constants and the bending strength for each series of cast iron by the method of least squares, and gave a series of curves of which only Fig. D is here reproduced, as representing the law of combined strength corresponding to the equation

$$M_0 = (1-A)M + A\sqrt{M^2 + T^2}$$

where M is the moment of bending, T the torsional moment, A a constant and M_0 the equivalent bending moment; that is

$$M_0 = \frac{\pi}{32} d^3 K \text{ if } d \text{ is the diameter of the rod subjected to the}$$

combined action and K , the bending strength (elastic bending strength for a ductile material). It was found that the St. Venant theory applies to cast iron in the most satisfactory manner. A plate is given showing the forms of fracture for one of the series of tests. Attention is called to the

fact that as the ultimate torsional moment is greater, the section of fracture is more inclined toward the plane normal to the rod axis (8 pp., 10 figs. c).

Tests on a Recent Type of Chain Grate Stoker and New Method of Baffling Stirling Boilers, John A. Hunter (abstracted)

The Relation of Educational Training to the Practice of Engineering, William H. Burr

TESTS ON A RECENT TYPE OF CHAIN GRATE STOKER AND NEW METHOD OF BAFFLING STIRLING BOILERS, John A. Hunter

The installation (Vandergrift Works of the American Sheet & Tin Plate Company) on which these tests have been made, consists of seven class M-22 Stirling boilers nominally rated at 600 h.p., containing 6032 sq. ft. of water heating surface and 396 sq. ft. of super heating surface. For draft it has an individual unlined steel stack 72 in. in diameter

above the pusher; after test 182 a change was made in the manner of operating the stoker designated as the "slow-chain" method of operation to distinguish it from the old method of "fast-chain." The slow-chain operation was used on the rest of the tests. In diagram B, the area under the dotted lines shows the character of the fuel bed with the fast-chain method of operation. The depth of the fuel bed is about the same over the entire grate except near the water-back, where it is piled up. The character of the fuel bed with the slow-chain method of operation is shown by the solid line on the diagram. Here the fuel bed is quite deep on the front part of the stoker and gradually thins out until it is about the same depth as the fuel bed of the fast-chain operation, with the exception of a point about 3 ft. ahead of the water-back, where it is also piled up.

With the fast-chain method, the distillation of the volatile gas of the coal takes place very rapidly and a large portion of it passes off in the flue gases and is burned, which is evidenced by the amount of smoke observed. The coal does not remain on the grate a sufficient length of time to have

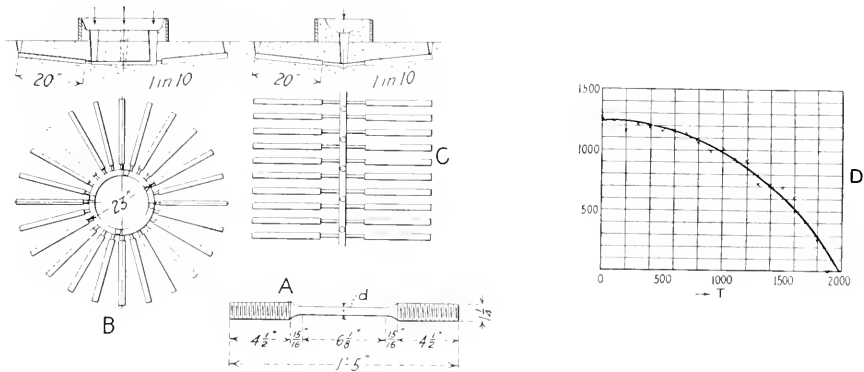

FIG. 5. METHODS OF MOLDING TEST-PIECES FOR TESTING THE STRENGTH OF CAST IRON

and 150 ft. high above the breeching. Each boiler is provided with one type "L" Green Engineering Company stoker, 10 ft. 6 in. wide by 12 ft. long, containing 126 sq. ft. of chain surface, the initial tests having been undertaken to determine if the guarantees made for the stokers could be met. During these tests, the baffles were arranged as shown in dotted lines on the drawing Fig. 6A and the openings at the end of the baffles were according to the dimensions in the circle. In place of the pressure water-back there was a single pipe supplied with low pressure water. These tests indicated that the efficiencies obtained were below the guarantee.

To meet this condition, the baffles were changed as shown in solid lines on the drawing and a special water-back was installed with two separate water boxes placed one directly over the other and each one connected to the mud drum and front steam drum, thereby insuring positive circulation throughout the box. All tests were conducted according to the Code of The American Society of Mechanical Engineers (the procedure is fully described in the original paper).

For tests numbers 180-182, the gate was about 63₄ in. above the pusher and in tests 183-189 the gate was about 71₂ inches

its carbon content completely burned. With the slow-chain method, the distillation of the volatile gas takes place quite slowly. All this gas is driven off by the time the thin portion of the fire is reached, and as there was practically no smoke except at very low ratings, it is thought that practically all the volatile gas is burned. The thin portion of the fire allows an excess of air to be drawn through the fuel bed at this point, which completes the combustion of the carbon.

A number of tables are given showing the results of the tests. From these tables, it is seen that efficiencies from 67.7 to 79.8 per cent and capacities from 74 to 195 per cent of rating were obtained. In regard to the percentage of combustibles in ash, it varies with fast-chain firing from 33 to over 44 per cent, while with slow-chain, it was maintained around 23 per cent and in one case went as low as 17.86 per cent. The flue gas temperatures with fast drive vary from 520 to 617 deg., and with slow drive from 417 to 550 deg., but excluding two cases of exceptionally high flue gas temperature, the average for the slow-chain method was around 450 deg., or apparently very much lower than with the fast-chain. The loss due to radiation varied from 2.55 to 5.70 per cent, with an average of 4.00 per cent for all the tests.

FIG. 6. NEW METHOD OF BAFFLING STIRLING BOILERS, "SLOW CHAIN" METHOD OF FIRING

The uniformity of these results would tend to indicate that no appreciable error has been made in taking the data.

Curve Fig. C shows the relation between the percentage of boiler rating and combined boiler and furnace efficiencies. The curve shown in solid lines refers to the actual efficiencies obtained from all the tests. The points below 150 per cent capacity are for the tests run with slow-chain method and points above 150 per cent capacity are for the fast-chain method, about 150 per cent of rating capacity being the maximum which can be obtained from this boiler with the slow-chain method of operation; so that when capacities above 150 per cent were desired, it was necessary to increase the chain speed, and change the operation to approach the fast-chain method.

By taking indicator diagrams from the engine driving the stoker, it was found that it required an average of 0.72 i.h.p. to operate the stoker. Allowing 80 lb. of steam per horse power hour, the following percentages of steam generated are required for the operation of the stoker: at 100 per cent rating, 0.35 per cent; at 150 per cent rating, 0.23 per cent; at 200 per cent rating, 0.17 per cent. Quantities so small that for all practical purposes the efficiencies obtained can be considered as net efficiencies.

In the discussion which followed, D. S. Jacobus stated that, in his opinion, the striking feature of the tests is the gain in efficiency due to the use of the slow-chain method as compared with the fast-chain. The heat balances show that this was due to a more perfect combustion and better ash. The lesser amount of smoke produced with the slow-chain method is also an item favoring efficiency. It is usually best to make an investigation of the method of operating furnaces rather than perfunctory tests and to depart considerably from what may be considered standard practice, in order to get the results. The speaker was present at one of the tests and was impressed with the great care which was exercised to secure accurate results.

John Wolff, of the Cleveland Electric Illuminating Company, stated that for some months past the station of his company was operating in a somewhat similar manner. It was found that for ordinary everyday operation, fixed conditions of fuel feed could be established and required no change from one month's end to the other, and that with these conditions established, it was possible to take care of momentary variations of load by simply manipulating the dampers. For peak work the speed of the chain only is increased, which is done by changing the chain feed from two to three teeth of the ratchet. With these manipulations a uniform steam pressure could be maintained as well as water level with little or no fluctuation, requiring few adjustments of the feed valve. One of the most important advantages of such a system is the extreme confidence which the operators feel in their ability to meet and handle all situations.

W. E. Snyder, of the American Steel and Wire Company, Pittsburgh, called attention to the fact that the determination of the efficiencies of boiler and grate depends on the knowledge of the correct heating values of the coal, as a high over-all efficiency may be obtained by ascribing to the coal a low heating value and showing the heat lost up the stack and to the ashpit as less than it actually was. From this point of view, the speaker, while believing that there may be a wide variation in the heating value of the coal obtained from

the same mine, calls attention to the fact that as shown by the paper, the heating value of the dry coal obtained from the same mine varied from 12,900 to 13,616 B.t.u. per pound. He recalculated the results in one of the tables, using the heating value of the coal given and the ash by analyses of the coal, and found that the average heating value per pound of combustible is 15,120 B.t.u. with a minimum of 1.1 per cent below the average and a maximum of $\frac{2}{3}$ of 1 per cent above the average, giving a close and consistent agreement among the samples. With the ash in the coal as determined by analyses, it can be used to check the quantity of refuse from the ashpit and its analysis. The author prepared a table by taking the total percentage of ash refuse that went to the ashpit and multiplying it by the percentage of incombustible matter which it contained. This gave a new percentage, which is the incombustible matter in the coal as determined by the analyses of the refuse from the ashpit. On the whole, he found that the ash in dry coal as determined by analysis of ashes from the ashpit is equal to 11.10 per cent and the average of the ash as determined by chemical analysis of the coal is 11.70 per cent, or a difference of 0.6 of one per cent, this difference being in the right direction, as the coal analysis should give a slightly higher ash because of some of the fine ash being carried out from the furnace over into the boiler and not being taken out of the ashpit. While in this manner a close constant agreement of data of ash content is secured, it is not possible to have an equally satisfactory check on the quantity of heat lost up the stack because the nature of the data does not permit it.

M. Alpern, of the American Engineering Company, Philadelphia, believes that an improvement can be expected in boiler maintenance through the elimination of the Stirling arch. The speaker referred to tests conducted at the Detroit plant on a five pass specially baffled Stirling boiler. Fig. D illustrates the total draft in the case of the Vandergrift specially baffled boiler with slow-chain and fast-chain method of operation. From these curves, it would appear that the limit of the available draft with the slow-chain operation was reached at approximately 155 per cent of rating, whereas the fast-chain method obtained a considerable higher rating. The Vandergrift boilers were operated at 125 lb. pressure. Additional data on the same boilers were supplied by T. A. Marsh of the Green Engineering Company of Chicago. The coal used at Vandergrift contained on an average 1000 B.t.u. less per pound than the coal used in Detroit and nevertheless the percentage of combustible in the ash at Vandergrift during the slow-chain tests was lower than that of the well known Edison plant at Detroit, although the furnace at Vandergrift is not as large as the one at Detroit and probably the combustion of the hydrocarbons was not as complete. On the other hand, the heat loss, due to radiation, was certainly higher at Vandergrift than at Detroit, due to the difference in the size of the units. T. A. Marsh has further prepared curves (Fig. E) showing the combustion rates per unit of draft obtained with the fast-chain method as compared with the slow-chain method. With the fast-chain method the combustion rate of 30 lb. of dry coal per sq. ft. of grate surface per hour, using a furnace draft of 0.30 in. water column; with the slow-chain method, the same draft was used for a combustion rate of only 21 lb., with the draft below the damper in both cases 0.90 in.

The speaker summarized the differences in results obtained

by the slow-chain method as follows: *a.* For the same combustion rate, a chain speed of less than one-half; *b.* A furnace draft of much greater intensity; *c.* Lower flue gas temperatures; *d.* Lower percentage of combustible in the ash; *e.* Higher percentage of Co_2 ; *f.* Practical elimination of smoke; *g.* Increased capacity due to increased efficiency at a given combustion.

Certain objections to the views and methods of Mr. Hunter were expressed by A. A. Straub, of the Duquesne Light Company, Pittsburgh. He considered the efficiencies obtained too high, and expressed the opinion that in this case efficiency has been obtained at the expense of flexibility in operation. He gave a diagram showing that the efficiencies decrease rapidly with increased percentage of rating contrary to the case in the Delray tests with under-fed stoker, where higher ratings were obtained.

J. E. Bell pointed out that the baffle at Vandergrift was not designed to produce a minimum draft loss or to absorb the maximum amount of heat from the gases; and it would appear that in this particular it answers the purpose. If a greater capacity should be required from a boiler with this baffle, the draft available at the damper must be increased by an amount corresponding to the rule that, at higher ratings, the draft loss is almost directly proportional to the square of the capacity, and to that should be further added the amount necessary to burn the additional coal.

In answer to questions, the author stated that no particular effort was made to prevent radiation, the brick work of the boiler not being covered with heat insulating material. As regards the efficiency curves shown by A. A. Straub, comparing data obtained at the Vandergrift tests with those obtained from tests made of the boilers in the Delray station of the Detroit Edison Company, the author pointed out that efficiencies obtained from chain grate stokers ought not to be compared with those from forced blast underfeed stokers without making a correction for the power required to operate the stokers. To this he adds the Table 1, showing the comparative efficiencies between the two sets of tests, the net efficiency with the slow-chain operation being slightly higher than those of the Delray tests, although it is true also that in some cases part of the steam which is required for the operation of the stokers can be recovered in the feed water heater.

The subject of determining the moisture in the coal brought up an extensive and interesting discussion, which cannot be reported here because of lack of space. (55 pp., 15 figs., c.t.).

Graphical Method of Finding Inertia Forces, Wm. J. Duncan (abstracted)

The Chemical and Mechanical Relations of Iron, Cobalt and Carbon, J. O. Arnold and A. A. Read

A GRAPHICAL METHOD OF FINDING INERTIA FORCES, William J. Duncan

The paper develops a graphical process for the solution of certain problems in the dynamics of machines. In it the fundamental element is the determination of the point called the acceleration center, and the author shows that this can be ordinarily done when the circle of inflections has been constructed. This latter is a curve representing the locus of

points in a body whose respective velocities and accelerations are parallel. It is so named because any point on it is momentarily at a point of inflection on its path. The locus of points, whose respective velocities and accelerations are perpendicular, may be called, according to the author, the circle of zero tangential acceleration. The author shows that a knowledge of the circle of inflections is of very material help in the determination of the acceleration center, and further shows how, having given the circle of inflections from which it can be determined and the direction of the acceleration of one point, the acceleration center can be constructed. In this way, he proves that the accelerations of all points in magnitude and direction can be found when the circle of inflections, the direction of the acceleration of one point and the magnitude of the acceleration of another point are known. He then proceeds to the discussion of the application of his constructions to the dynamics of machines:

TABLE 1 COMPARATIVE EFFICIENCIES OBTAINED IN THE VANDERGRIFT AND DELRAY TESTS

Percent Rating Developed	Vandergrift Tests Slow-Chain Method		Delray Tests	
	Gross Efficiency	Net Efficiency	Gross Efficiency	Net Efficiency
74	79.82	79.4	80.2	77.7
110	77.45	77.1	79.0	76.4
126	76.00	75.7	78.5	75.8
148	75.86	75.6	77.8	75.0

for example, theory of a link of a four part mechanism; oscillating cylinder mechanism, such as an oscillation engine, accelerating force on the piston and piston rod; determination of the inertia forces in a Gnome engine, etc. Stricter mathematical proofs of the statements and constructions proposed in the body of the paper are given in an appendix (30 pp., 25 figs., *tm*).

The Lateral Friction of Winding Ropes, H. W. G. Halbaun (abstracted)

Winding Engine Signals, Wilfrid H. Davis

The Nature of Explosions, Professor Harold B. Dixon

THE LATERAL FRICTION OF WINDING ROPES, H. W. G. Halbaun

In this article is discussed the question of lateral friction of winding ropes, in particular for the case of the ordinary wide drum. It is claimed to be merely an attempt to state the problem in the simplest terms.

A is the angle of maximum friction. When the rope between the pulley and the drum lies in the same vertical plane as that of the pulley, there is no lateral friction. This line of no friction is called by the author, the "center-line." When the rope has diverged to its utmost limit from the center-line, it makes an angle A with that line, called the *angle of maximum friction*. Under no circumstances need it exceed 3 deg., and in many cases 1 deg. During the wind-

ing, the angle of friction varies from zero to A , but it is the maximum angle only that must be taken into account, since it is invariably the same portions of rope which suffer from its influence in each successive wind.

Several ways have been proposed to reduce the angle A , for example, by reducing the width of the drum so that the rope is obliged to coil upon itself during the latter half of the wind. A may also be kept at its lowest possible value by so attaching the rope to the drum that it lies truly on the center-line when the cage is at "meetings" or half-depth. In some cases there may be a little difficulty in the centering of the rope at the middle point of the winding, but this difficulty might easily be overcome by fitting the winding drum, or at any rate the lower portion of the wind, with a spiral screw-thread, which would guide the rope in the path required to insure its centering itself at the middle point of the wind. This spiral screw-thread is not grooved, however.

The author develops the following formula, for which it is assumed that the normal diameter of the rope is d inches, the width of the drum employed by each coil of rope on the drum is $1.1 d$ inches, the rope being centered at "meetings":

$$A = \frac{10H}{RL}$$

where H is the height of the banking-level above the onsetting-level, L the length of rope extending from the pulley to the drum and R the ratio of the drum diameter to the normal diameter of the rope (in practice from 110 to 150); H and L may be taken in any units, but both must be in similar units. If it be ordered that A shall not exceed a given predetermined numerical value, the winding engine must either be placed at such a distance from the pit

that $L = \frac{10H}{AR}$ or the drum must be of such a diameter that $R = \frac{10H}{AL}$, that is to say, if D is the diameter of drum, and d diameter of rope (both in similar units), the following formula must be taken: $D = d \cdot \frac{10H}{AL}$.

The above formula shows that since H cannot be altered for a given mine, A can be reduced only by increasing L or R or both. L may legitimately be extended to 50 yd. (there is an objection to making it too long because many managers prefer the engineman to have a clear view of the banking operations and cages), and then a reasonable value of R will reduce the angle A to about 1.5 deg., even in the case of the deepest British coal mine, always provided that the ropes are so adjusted as to center themselves at "meetings." In the case of shallow mines, the lateral friction should be quite a negligible quantity.

The author, among other things, comes to the following conclusions: Other things being equal, the lateral friction varies as the square of the angle A of friction; other things being equal, the destructive character of the lateral friction varies with the roughness of the rope; hence, ropes of the flattened-strand and locked-coil type suffer less than ropes of the ordinary type, because the coefficient of friction is less. Lubrication reduces lateral friction.

In the discussion which followed numerous objections were made to the statements of the above speaker.

Hugh Bramwell, who lately installed at the Cwm Colliery, Pont-y-pridd, Wales, a hoist to raise 12 tons of coal per wind, from a depth of 800 yd., stated that the maximum per-

missible lateral angle should be limited to 2 deg. as an outside figure. In a case within his knowledge, where 2 deg. had been exceeded, the lateral wear on the rope (locked-coil) was material. In the Cwm Colliery installation, the rope was allowed to overlap, this being done to reduce the size of the drum. In that case, the choice lay between a 30 ft. diameter drum weighing, with its shaft, some 150 tons, and no overlapping, and a drum little more than half that diameter, weighing much less, but with overlapping. Mr. Bramwell's opinion was that there was less rope wear when there was overlapping with a lateral angle of 1 deg. than with no-overlapping and a lateral angle of 2 deg.

With regard to the same installation, G. W. Westgarth stated that with the flattened-strand rope 3 in. in diameter, the difference between the load at the start and at the finishing point, due to the weight of the rope alone, would be approximately 16 tons, but if a locked-coil rope 3 in. in diameter were adopted, the difference would be approximately 22 tons. He suggested that these weights were in such relationship to the useful load of 12 tons that there could be gained by their adoption, so far as the lateral angle is concerned, not only a negligible advantage, but a serious disadvantage, and the inference was that in laying out winding engines, it was most desirable that the lateral angle should be arranged for the adoption of such a rope that its weight would be in more economic relationship to its useful load.

An important point in connection with the same installation was that of selecting a proper factor of safety. Having regard to the low cage speed of about 30 ft. per second, and after taking into consideration the smooth running and direct control obtained by the use of an electric winder, it has been decided to adopt a safety factor of about 7 in lieu of the customary 9 and 10; a further reason which prompted the taking of this step is that with so large a dead load there would still be a much larger absolute margin of strength than usual, although a smaller relative margin. Thus a dead load of 20 tons and a factor of safety of 9 gave a margin of 160 tons, while with a dead load of 40 tons and a factor of safety of 7, the margin would be 240 tons (30 pp., 4 figs. *et*).

SOME TESTS ON A DIESEL ENGINE, W. S. BURNS

The paper presents data on some tests of a Diesel engine carried out in the laboratory attached to the Department of Mechanical Engineering in the Royal Technical College, Glasgow. The present paper covers the following subjects; value of blast pressure and variation of jacket water temperature upon the running of a Diesel engine. It also describes some of the measuring apparatus used. Further data obtained from the same tests are reported in the author's paper, "Oil Fuels and Their Application to the Generation of Power," in the *Transactions of the Institute of Engineers and Shipbuilders in Scotland*, Vol. 57.

From the beginning, it was seen that the ordinary indicator diagram would not be suitable for the investigation of changes taking place in the cylinder during combustion. The combustion part of the cycle in a Diesel engine takes place when the piston is moving very slowly, so that with the usual reciprocating indicator diagram, the record of the pressure changes is crowded into a very small space. Consequently rotary indicator cards were used, and the author fully describes the method of taking such diagrams. As shown in Fig. 7A, the spring and stopper were removed from the indicator barrel, and a card consisting of a circular strip of paper, about 33 in. long by 2½ in. broad, was passed over the indicator drum and also over a wooden drum affixed to a small spindle parallel to the indicator drum. The spindle was driven from the crank shaft and was fitted with a clutch for starting and stopping the cards. To record the position of the beginning of the stroke on the cards, an electrical striker was fitted to the indicator and so adjusted as to make a mark just beneath the indicator pencil when the piston was

at top dead-center. It was obtained by placing an indicator on the fuel valve in such a way that vertical displacements of the indicator pencil were proportional to the movement of the fuel valve spindle, the indicator drum being driven at a constant angular velocity by a cord from a wheel on the countershaft spindle. Elsewhere the two short vertical lines, one near the top of the compression curve and the other some distance down the expansion curve, indicate the opening and closing of the fuel valve of each diagram.

Experiments With Different Blast Pressures: Several series of tests were run at different blast pressures, the load remaining constant throughout each series. The usual increase of consumption with unsuitable blast air-pressure was found. For example, by dropping the blast air-pressure from 700 to 600 lb. per sq. in. at normal load (about 30 b.h.p.) the consumption is increased by about 0.37 lb. per hour. The diagram shown in Fig. M can be considered typical. The expansion line on diagram A shows, as at lighter loads, that the oil burns late in the stroke probably because

FIG. 7. A AND B. ARRANGEMENT FOR TAKING ROTARY INDICATOR DIAGRAMS

at top dead-center. The striker was adjusted to a known point on the ordinary receiving card, the adjustment being made at the electrical contact at the flywheel as shown in Fig. B.

The load was kept practically constant throughout each series of tests by adding and taking off small weights, according to whether the rope friction decreased or increased. Before starting a series of tests, the engine was run from 2 to 3 hours at the load required for that series, to insure a steady temperature condition throughout. Fig. C shows a rotary diagram taken immediately after the fuel was shut off, giving the compression and expansion of the air in the cylinder under working conditions. Equal increments of length on the atmospheric line of this diagram represent to scale equal increments of crank angles. The cards travel about 7.6 in. in one revolution, or about 25.6 in. per second, so that the paper was travelling under the indicator pencil at high speed relative to piston displacement at top and bottom dead-centers, this permitting the studying of changes of pressure in the engine cylinder at and around those points in great detail.

On one of the diagrams is shown the motion of the fuel valve to a modified scale relative to the indicator dia-

gram. It is not properly pulverized, thus causing increase of exhaust temperature and pressure above normal. Diagram B shows that combustion begins almost at the top dead center and the burning is completed considerably earlier in the stroke.

In diagrams C and D the blast pressures caused considerable irregularity about the point of ignition; sometimes combustion starts at the top dead-center, in which case a smooth expansion curve is obtained, or the pressure line followed down the dotted expansion line for some distance, when there is a sudden addition of heat, causing a peak in the expansion line. The late ignition may be due to the cooling action of the blast air. Diagram E shows the ignition later than D, with a more rapid explosion of the oil, causing a slight knock in the engine cylinder. The diagrams in Fig. N are likewise reproduced here to show how an increase in blast pressure up to the most economical pressure, increases considerably the rate of combustion of the oil. At high blast pressures, ignition is retarded and is attended by a sudden rising pressure, causing peaks on the diagrams. The ragged end of the expansion line of the diagram C is caused by the vibration of the indicator spring and mechanism, due to the sudden increase in pressure.

On the whole, it was found that at light loads, the excess air already in the cylinder and the inrush of blast air, with a small quantity of oil, causes late ignition and slow combustion of the fuel. Then as the load increased and the mixture of pulverized fuel and air becomes richer, there is a correspondingly earlier ignition and also an increase in the rate of propagation of the explosion. At all loads, too low a blast pressure pulverizes the oil imperfectly, causing late ignition and incomplete combustion with an increase of ex-

haust gases at the high temperature, which also indicates that the oil is being handled more economically. The heat given to the cooling water per unit of time at low temperature is about five times as great as the heat given at the high temperature. Tachograph records show that increase in jacket water temperature causes a slight increase of speed, principally due to the cylinder lubricating oil becoming less viscous at the high temperature.

Diagrams *A* and *B*, Fig. O, show that at moderate tem-

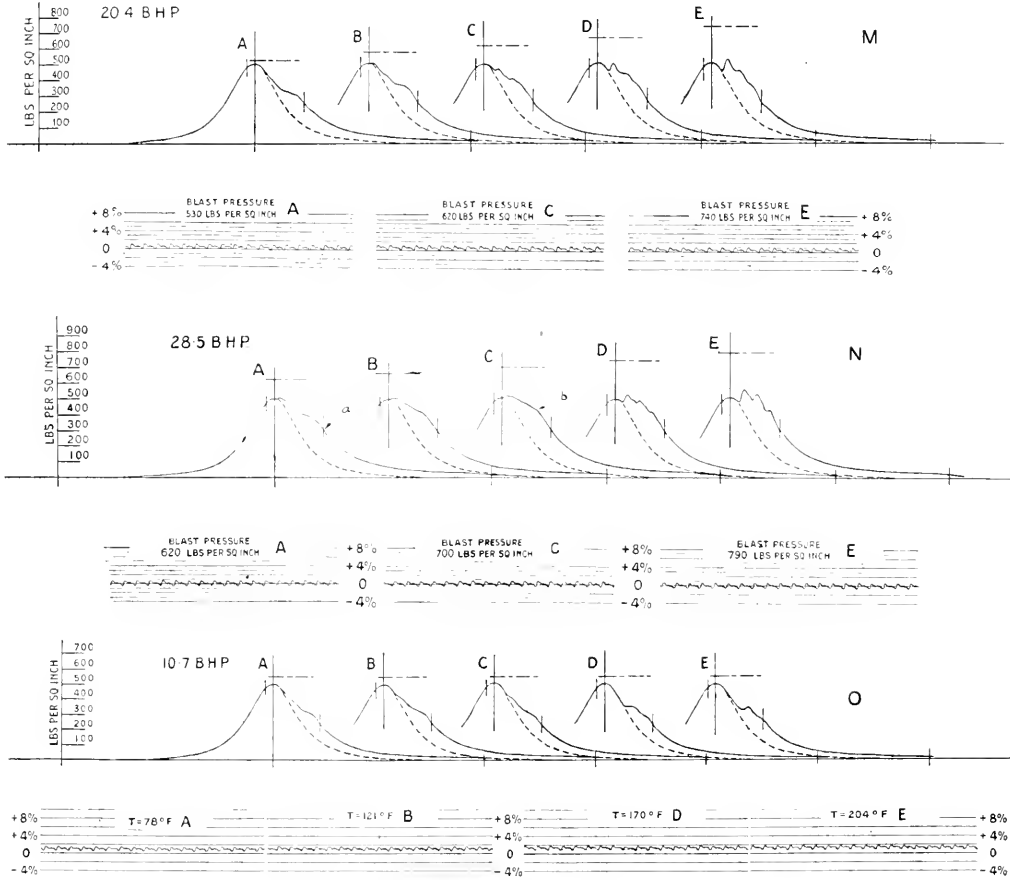

FIG. 7, C, D, E DIESEL ENGINE INDICATOR DIAGRAMS TAKEN WITH DIFFERENT BLAST AIR-PRESSURES

haust pressure and temperature above normal, while too high a pressure causes late but violent ignition again attended by incomplete combustion of the oil.

Variation of Water Jacket Temperature. Fig. O illustrates the effect of the variation of cylinder water jacket temperature at low load; a similar figure in the original article shows the same at high load. It was found that the higher the temperature of the jacket water, the more economical was the engine. There is a marked decrease in the carbon dioxide and the carbon monoxide present in the ex-

peratures combustion takes place late in the stroke and the rate of combustion is slow, while diagrams *D* and *E* show that as the temperature of the cylinder walls and piston increases, ignition still occurs late in the stroke, but that the rate of combustion is more rapid. As a general conclusion, the author states that at all loads, increase in water jacket temperature does not seem to affect the point of ignition of the oil, but probably causes more rapid and more complete combustion with increased efficiency.

In the discussion which followed, Professor A. L. Mel-

lanby called attention to the effect of varying the blast pressure and to the sensitiveness of the engine in responding to these changes of pressure. In Fig. N the diagrams show what takes place when the engine is working under fairly high loads. Examination of the card *A*, taken when the blast pressure was low, shows that ignition takes place earlier and that the oil burns quietly and comparatively slowly. Card *E*, taken when the blast pressure was high, shows that ignition was late, due probably to local cooling effect and that a comparatively violent explosion took place. James Richardson pointed out that Mr. Burns' work showed that at the lowest powers the conditions of fuel injection were generally a compromise between a quantity of compressed air required to pulverize satisfactorily the fuel and the cooling effect of the expansion of this compressed air as retarding ignition.

ON THE STRENGTH OF WELDS MADE BY THE OXY-ACETYLENE
PROCESS, Professor Campion and W. C. Gray

The paper presents a general discussion on acetylene welding as well as data on the strength of welds by that process. The author starts from the statement made by Dr. C. H. Desch, to the effect that it must be admitted that a joint made by autogenous welding has not the same qualities as the original steel. Tensile tests are not conclusive in showing which part is injured, as the injury to the steel does not always affect the tensile breaking strength, but is revealed when the welded steel is subjected to shock or fatigue.

For the purpose of the present tests, a large number of welds of mild steel were prepared and submitted to static tension and repeated impact tests in the ordinary condition and also after various treatments. The first series of tests were made of round bars of mild steel, 5/8 inch in diameter, containing approximately 0.25 per cent carbon. No results for contraction of area at fracture have been recorded because it was found that in most cases the fracture was much too ragged and uneven to allow of the final diameter being measured. In the results of tensile tests considerable differences were found, not only between the mean results for each treatment but between the individual bars of each set. This appears to indicate that there is an element of uncertainty about a weld, even when it has been made with the greatest care by an expert manipulator. Altogether, it would appear that an average weld might be expected to possess something like four-fifths of the strength of the unwelded steel and that the ductility would be about one-fifth. The maximum strength in tension appeared to vary to no great extent, but the ductility varied considerably from the average.

Hammering increased the ductility and reduced the strength slightly. Reheating after hammering produced a further increase in ductility and at the same time increased the maximum strength. Reheating to the same temperature without previous hammering produced a somewhat larger increase in ductility and a further small increase in strength. In specimens quenched in water and then reheated, the strength has risen to almost that of the unwelded material although elongation has been reduced. From all tests, it appears that under no circumstances does the ductility of the weld approach that of the unwelded portion.

A number of welded bars of the same material were tested under repeated impacts in a Stanton machine. The bars were notched in the center of the welded portion, the

diameter at the bottom of the notching being four-tenths of an inch. From these tests it appears that an average weld might be expected to withstand about half as much as similar material unwelded. Hammering has been apparently the most effective treatment so far as increasing the fatigue resisting properties of the material is concerned, but it must be borne in mind that the heating during the welding is extremely local and consequently the metal in the immediate vicinity of the weld is liable to be at a comparatively low temperature and there is danger, when hammering, of vibrating or jarring the portion of the metal that is at black heat, which is productive of brittleness. If hammering is resorted to, the metal should be reheated to a full red heat (800 deg. cent.) in order to remove strains or brittleness which might have been set up during the process.

Reheating or annealing alone appears to be of little value so far as the increasing of fatigue resistance in the welded portion is concerned. This fact, of a portion of the material in close proximity to the weld becoming brittle from being heated to a black heat, explains also the fact observed in the tests; viz., that fracture occurred not in the center of the weld where the notch was, but in close proximity to the weld. Several microphotographs in the original article show the fracture of the original plate and that of the overheated portion after annealing.

A series of repeated impact tests on plates of different thicknesses have shown very clearly that the thicker the plate, the less reliable is the weld and the greater the reduction in strength. Thick material also generally shows less improvement by annealing.

The authors, as the result of a large number of tests and experiments upon autogenous welds, conclude that although there is a wide field of usefulness for oxy-acetylene and similar processes, considerable precaution must be exercised and due regard paid to all the conditions before making use of them, especially where the parts are likely to be subjected to considerable mechanical strain. In any case where failure tends to endanger life and limb, welds, if not entirely prohibited should be accepted with extreme caution.

In the discussion which followed, James T. Milton stated that there had been a great deal of pressure brought to bear upon Lloyds' to accept all kinds of repairs by autogenous welding but, up to the present, no repairs made by this process were accepted in places where if they failed it would mean serious disaster. Lloyds' Register prohibited, and continues to do so, the use of autogenous welding on shell plates, both of ships and of boilers and also on large and important forgings. Neither are crank shafts, repaired by autogenous welding, accepted.

Dr. C. H. Desch pointed out the desirability of distinguishing between the processes of true welding in which the metal was quite continuous in composition and structure throughout, and autogenous welding in which a zone of material fused at a high temperature was produced bordered by two zones of overheated metal. The present experiments confirm the speaker's view that the presence of a zone of overheated metal was very injurious to the dynamic properties, and that subsequent treatment did not restore the original resisting power. It was quite possible for the fused portion to be stronger in every way than the original metal; the weaker part was the intermediate overheated zone (20 pp., 4 figs. *eg*).

THE INFLUENCE OF VARIOUS TEMPERATURES ON THE PROPERTIES OF ADMIRALTY GUN METAL, Professors A. Campion and John G. Longbottom

Investigation of the influence of various temperatures on the properties of admiralty gun metal, annealing of such metal at various temperatures, and of variations in the structure of the metal when heated.

The actual composition of the material used in the research is shown by an analysis, in percentages,—copper, 87.96; tin, 9.77; iron, 0.13; lead, 0.18 and zinc, 1.94.

The tests have shown that from atmospheric temperature to about 200 deg. cent., the material suffers no appreciable change of structure. From 200 to 250 deg. cent., the results are somewhat irregular with a general indication of decreasing strength. From 250 deg. cent. the strength falls continuously until at 750 deg. cent. it is approximately nil, the ultimate elongation appearing at first to increase slightly with rise of temperature, reaching a maximum at about 140 deg. cent. At temperatures higher than this, the elongation rapidly diminishes until at 350 deg. cent. it is less than 1.5. At temperatures below 200 deg. cent. the modulus of elasticity is practically unaffected by change of temperature. Very careful tests were made to determine the constants in Unwin's equation, showing the percentage of elongation.

The results of the authors' tests compared very closely with those of Bach, as well as with those of Unwin, the latter being of particular interest because Unwin's bars were cast at different times and his tests were quite few in number. On the other hand, a marked disagreement occurred between the results of the authors, Unwin and Bach on one side and those of Dewrance on the other.

As regards the influence of annealing at different temperatures, the authors found that annealing at 250 deg. cent. produces quite as satisfactory results as annealing at 700 deg. cent., which latter has sometimes been recommended. On the other hand, however, at 700 deg. cent. the material is devoid of both strength and ductility and extreme care is necessary in the handling of the castings of large size or intricate form. Moreover, the temperature of 700 deg. cent. is dangerously near the temperature at which burning of the material would take place and a small sudden rise of temperature might severely injure, if not completely destroy the casting. Further, at a temperature of 250 deg. cent., the effects of oxidation are comparatively small. It would appear therefore that annealing at 250 deg. cent., apart from cost, offers great practical advantages as compared with that done at the higher temperature.

A careful examination of the structures of the material at various temperatures was made. A study of the equilibrium diagram of the copper-tin series of alloys indicates that little or no change should be produced by heating the material to temperatures below 450 deg. cent., followed by a moderately rapid cooling, except a growth of crystals and possibly some diffusion and redistribution of β constituents. The specimens heated to temperatures below 200 deg. cent. showed that such was the case, but at 250 deg. cent. a somewhat remarkable and unexpected change in the structure was found to have taken place, the β compound having apparently been almost completely absorbed by the primary and secondary α resulting in a nearly homogeneous structure typical of a solid solution. It is of interest that no provision for such a change is made in the equilibrium diagram as at present constructed from the works of Shepherd, and of

Heycock and Neville, and the authors declare themselves unable to offer an explanation of this remarkable change.

It was found further that sudden changes in mechanical properties occur at temperatures at which, up to the present, no critical points have been recognized in the thermal curves of alloys containing over 80 per cent of copper. With the exception of the remarkable change at 225 deg. to 250 deg. cent., the microstructure of the material shows no changes sufficient to account for the alteration of mechanical properties at various temperatures and it must consequently be inferred that they have no relation to the phase changes in the alloy. In the original article a number of fractures are reproduced in actual colors, which shows clearly the remarkable manner in which the crystals grow with increase of temperatures. An examination of the series of micrographs showed that in all cases fracture appears to take place through the portion richer in tin, which filled the space between the primary α .

The authors believe generally that the crystals are bound together by some form of cementing material, which, upon heating, loses its adhesive properties and consequently when stress is applied, the crystals composing the mass are parted from each other.

The authors point out further that the temperature of 250 deg. cent. corresponds to the point on the curves where the strength and ductility falls rapidly off and also that it is just at the outside of the zone of irregularity previously referred to. Likewise, this happens to be the annealing temperature at which the maximum strength and ductility are obtained, while at 260 deg. cent. the thin continuous bands of $\alpha + \beta$ complexly reappear. The authors consider that the result of their investigations furnishes strong evidence in support of the existence of some form of cement between the crystalline boundaries upon which the strength and other properties are largely dependent. The authors believe that the "amorphous material" of Beilby is identical with the "cement" of Rosenheim and Ewen, although no direct experimental evidence to prove it is as yet available.

The authors have noticed, however, during the course of the present investigation, certain phenomena which appear to furnish strong evidence in support of this view. It is a known fact that in these metals at some temperatures marked slips occur after the yield point is passed, but after a short time the material stiffens and carries a farther load. In some cases as many as ten such slips have been observed between the yield point and the maximum stress of the material. These slips are invariably accompanied by an evolution of heat. In the opinion of the authors this is due to the amorphous cement crystallizing to such an extent that the adhesion between the crystals of the metals is reduced sufficiently to allow some of the crystals to part from their neighbors under the particular stress. Actual fracture is prevented, however, by the crystal faces rubbing one against the other with considerable pressure, thus reforming a quantity of the amorphous material, with the result that adhesion is again restored. This material is in turn recrystallized under the influence of heat and another slip takes place.

In the progress of tests in the present investigation it has been noticed on several occasions that the temperature suddenly rose several degrees, which in the earlier experiments was attributed to changes of voltage in the heating current. Very close observations during the later tests on the gun

metal resulted in the interesting discovery that, immediately after each of the slips mentioned above, an appreciable increase of temperature in the material took place. This observation appears to be new.

The author considers that the amorphous cement loses its ductility at a lower temperature than that at which it loses its strength, and consequently the ductility of the material deteriorates more rapidly than the strength with increasing temperature.

A brief bibliography is appended (36 pp., 38 figs. c).

WESTERN SOCIETY OF ENGINEERS

Journal, vol. 20, no. 4, April 1915, Chicago

Operating Results of the Electrification of Steam Railways, George Gibbs, Edwin B. Katte, W. S. Murray and C. A. Goodnow (abstracted)

Founding of the Western Society of Engineers, Walter Katte

Wind Stresses in the Frames of Office Buildings, Albert Smith, W. M. Wilson (abstracted)

OPERATING RESULTS OF THE ELECTRIFICATION OF STEAM RAILWAYS, George Gibbs, Edwin B. Katte, W. S. Murray and C. A. Goodnow

The data presented by the speaker showed that as compared with steam operation, the first cost of electrification is not in its favor. For example, a modern steam locomotive costs about \$25,000 and an electric locomotive of the same capacity, \$40,000. The cost of power station, transmission lines, sub-stations and working conductors must be added to that, which will bring the equivalent cost up to \$110,000; hence, there should be a large saving in operating cost to cover the increased fixed charges, or another good reason for incurring the additional expense. The New York Central electrified its lines into Grand Central Terminal because it has a bad four-track tunnel condition to deal with at the most congested point of traffic, but when electrification was decided upon, it resulted in very radical changes in the movement and operation of the trains. This latter fact makes direct comparison between the former steam and the present electric operation impossible and only a general comparison can be made. The average cost per locomotive mile from a large number of records has been found to be, on steam roads, about \$0.26 including fuel, supplies, maintenance, repairs and enginehouse expenses. A similar figure for electric locomotives in and about New York City can be found to be about \$0.21. If, however, fixed charges are added, the comparison becomes \$0.30 for steam locomotives and about \$0.60 per mile for electric locomotives, this, however, without taking into consideration the fact that conditions in the New York case permit an average of 85 miles per day for electric locomotives while the steam locomotives are averaging about 150 miles per day.

As a measure of the reliability of electric equipment comparison of the locomotive or car miles per detention is used. During the year 1914 the average locomotive miles per detention was 23,000 while the multiple unit cars averaged 51,000 miles per detention. The train minute delays due to electric power troubles totaled 840 minutes for the year, out of which 535 train minutes were due to aerial lines, 244 minutes delay to the third rail, 25 minutes to sub-stations and not a single minute's delay during the eight years of operation, to power stations. The electric locomotives used by the New York Central in express passenger service have a speed of 60 miles per hour when drawing a 1,200 ton train.

The locomotive is equipped with an oil-fired flash type boiler having a capacity of 2,000 lb. of water per hour for heating through trains. The complete weight of the locomotive is 132 tons, all of which is carried in the drivers, thus giving a draw-bar pull of 66,000 lb. assuming 25 per cent adhesion.

WIND STRESSES IN THE STEEL FRAMES OF OFFICE BUILDINGS, Professor Albert Smith

The paper presents methods of computation of two, three and four bay buildings, the calculation being carried for the case of two bay buildings to the ninth story, and for three bay to the fourteenth. The author uses the method of least work, and asserts that no reliance should be placed, for safe distribution of stresses, upon the passing of the elastic limit by some fibers of an office building. The paper is of great interest, but because of its mathematical nature entirely unsuitable for abstracting. The author believes that the results given in the paper are not usable in the first and second stories, but that for buildings whose bays are equal these results will give very reliable indications of the stresses above the second floor.

WIND STRESSES IN THE STEEL FRAMES OF OFFICE BUILDINGS, Professor Wilson

The paper, presented jointly with the above paper by Professor Smith, begins by establishing certain assumptions upon which the analysis is based. From these, and certain fundamental equations, the author determines the stresses in the frame. He shows that it is possible to write as many equations for each story as there are columns in the story, plus one. As the only unknown quantities in these equations are the changes in slopes at the extremities of these columns, and the deflection in a story common to all columns, there are as many equations per story as there are unknowns. By solving these equations the slopes and deflections can be determined, and this permits one to determine the moments, which in their turn make it possible to determine the shears. With the shears in the girders known, the direct stress in any column can be determined by taking the column as a free body and equating the sum of the vertical forces equal to zero.

The paper gives further a detailed comparison of the "approximate method" with the slope-deflection method of computation, the "approximate method" being described in full. As regards the slope-deflection method, the author states that it contains no approximations, except those contained in the original assumptions, and it can be shown that the inaccuracies in the assumptions do not affect materially the results; therefore, the stresses in a frame as given by the slope-deflection method will be very accurate. The greatest value of the method is said to be not for purposes of actual calculation of buildings, but as a standard by means of which the accuracy of the approximate methods may be determined.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *d* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

MEETINGS

BOSTON, APRIL 23

NEW HAVEN, APRIL 21

The regular spring meeting of the New Haven Section was held in New Haven on April 21. The general subject of the meeting was The Development of Machine Tools, and six papers were presented on different aspects of the subject as follows: The Early History of Machine Tools, by Prof. Joseph W. Roe, Sheffield Scientific School, Yale University; Modern Developments in Milling Machines, by Luther D. Burlingame, Brown and Sharpe Manufacturing Company, Providence, R. I.; Milling Cutters and Cutting Tools, by A. L. DeLeeuw, Singer Manufacturing Company, Elizabethport, N. J.; Modern Development in Vertical Boring and Turning Machines, by E. P. Bullard, Jr., The Bullard Machine Tool Company, Bridgeport, Conn.; Special Forms of Presses for Working Sheet Metal, by Darragh deLancey, Waterbury, Conn., and Grinding as a Manufacturing Process, by H. W. Dunbar, Norton Grinding Company, Worcester, Mass.

The meeting was divided into two sessions, one in the afternoon and one in the evening. A portion of each session was given up to discussion of the papers presented at that session. The registration was 125, of whom 69 were from places outside of New Haven.

CINCINNATI, APRIL 22

At a joint meeting of the Cincinnati Section and the Engineers' Club of Cincinnati, held on April 22, W. C. Devereaux spoke on Forecasting the Weather. The address was illustrated by lantern slides, and by such of the instruments of the Weather Bureau as may be easily transported, including the sunshine recorder, wet and dry bulb thermometer for indicating the humidity, and recorders for wind velocity and direction. The speaker outlined the methods used in obtaining the temperature, velocity and direction of the currents of air in various strata above the surface of the earth, and showed the development of a storm and its progress across the surface of the country by successive weather maps, and gave reasons for the storm's progress. The weather maps for the days of unprecedented rainfall in March and April, 1913, when the great floods occurred in the Miami Valley, were shown and discussed. The speaker concluded his remarks by a discussion of the methods used in predicting the weather in Cincinnati. About 75 members and guests were present.

MINNESOTA, APRIL 22

A meeting of the Minnesota Section of the Society was held on April 22, at which D. W. Flowers, of the St. Paul Gas Light Company, gave a paper on The Manufacture of Illuminating Gas. Mr. Flowers confined his remarks to the manufacture of coal gas, carburetted water-gas and oil gas. He outlined in an elementary manner the principal features of the generation of gas by these three processes, and referred to the characteristics of the materials used in gas manufacture, such as coke, tar and ammonia liquor. He discussed the advantages of the various systems, pointing out the economic considerations which, in the vicinity of St. Paul, lead to the manufacture of all-water gas. He concluded with illustrations descriptive of oil gas apparatus, coal gas apparatus and water gas apparatus.

A joint meeting, under the charge of the A.I.E.E., was held on April 23, at which Frank W. Hodgdon, chief engineer for the directors of the Port of Boston, presented a very interesting paper on the Electrical Equipment used in the Commonwealth Pier Development for the Port of Boston. Mr. Hodgdon did not confine his remarks to the electrical equipment, but gave many details of dock and building construction, presented a large number of lantern slides, and treated the entire subject in a very comprehensive way, which led to considerable discussion at the close of his talk.

BUFFALO, APRIL 27

A meeting of the Buffalo Engineering Society was held on April 27, at which Charles W. Parker presented a paper on Patents. Mr. Parker went into a thorough discussion of the patent laws of this country, with a full description of the various kinds of patents which can be obtained and a complete description of the methods which are followed by patent attorneys and by the patent office in Washington.

Another paper was presented by H. V. Alverson on Conservation, referring to the conservation of Niagara Falls Power. Mr. Alverson's paper dealt with the development of the power plant at Niagara Falls, with complete statistics of the power being generated and the power available, due to the flow of water in Niagara River. He also gave complete information regarding the distribution of the power in Buffalo and the surrounding cities, both in this country and in Canada. After the reading of the paper, a spirited discussion ensued, led by F. A. Ladbury of Niagara Falls, and a resolution was presented empowering the president to appoint a committee for the purpose of investigating the power situation and presenting a report to the society for their action in connection with a meeting of the Central Council of Business Men's Association, which is arranging a conference of manufacturers, Boards of Trade and Business Association of Western New York Municipalities to effect a permanent organization for a persistent movement to obtain low prices for Niagara Falls power at as early a date as possible.

At this meeting, the following officers for the ensuing season were elected: John Younger, president; W. A. James, 1st vice-president; J. G. Melendy, 2nd vice-president; W. J. Gamble, secretary; W. M. Dollar, treasurer, and David Howard and David Bell as directors for two years.

The final meeting of the season was held on May 6. This meeting was addressed by Prof. R. C. Carpenter, of Cornell University, on Concrete and Machinery for Making Cement. Professor Carpenter presented some very interesting details on the subject, and, during the discussion which followed, he gave additional interesting information. This meeting closed the season of the Buffalo Engineering Society, which now has a membership of about 325. During the season, fourteen meetings were held and the average attendance was about 150 to 175.

NEW YORK, MAY 11

A meeting of unusual interest was held on May 11 by the New York local section on the newly developed process of metal spraying. The paper of the evening, entitled Metal Spray Processes in Engineering and Art, was presented by John Calder, member of the society, who traced the de-

velopment of the school process from the early beginning in Europe down to the improved American processes, and discussed not only the interesting theoretical considerations involved, but also the features of practical interest in the use of the process. He showed the details of the spraying instrument by slides, and pointed out the limitations of the process in certain directions. Interesting data was also given relative to the cost of spraying the various metals, and as to the costs of the blaw-gas, oxygen and compressed air used. The lecture was followed by a practical demonstration of the process in the basement of the Engineering Societies Building, at which a commercial spraying instrument was shown in operation, coating various objects of metal, wood, stone, cloth and paper with brass, copper, zinc and aluminum. A more complete account of the meeting will appear in an early issue of *The Journal*.

NECROLOGY

JAMES McBRIDE

James McBride, a member of the Society since 1886, was born on April 27, 1836. When he was a very young man, he learned the trade of pattern maker. From 1858 to 1865, he was employed by the Dueschne Engine Works at Pittsburgh at pattern making and the erection of machinery on steam boats. During this period he assisted in the erection of the machinery on thirty-seven boats. It was at this time that he obtained a Government license for engineer of the 2nd Class on the western rivers.

In the four years that followed, he established a pattern shop of his own in Pittsburgh in which he made patterns, mechanical drawings and designed machinery. He gave this up, however, to take a position as draftsman for the Root Steam Engine Company of New York, but later returned to the Dueschne Engine Works as draftsman and designer. In 1876, he entered the employ of the New York Dye Wood Extract and Chemical Company of Brooklyn as chief engineer. Three years later, he became superintendent of the Stamford Manufacturing Company in Stamford, Conn. Mr. McBride died at his home in Stamford, Conn., on April 13.

WILBER H. TRAVER

Wilber H. Traver was born at Mattawan, Michigan, on May 3, 1863. He had a common school education, but as the mechanical profession and especially railroad work appealed to him very strongly, he served an apprenticeship with the Michigan Central Railroad as a machinist from 1880 to 1883. In 1889, he became master mechanic for the Atchison, Topeka and Santa Fe Railroad and, following this, he held the same position with the Kansas City, Pittsburg and Gulf Railroad. In 1895, he took a position with the Rand Drill Company in the sales department and later became manager of the Chicago office of this company.

In 1906, Mr. Traver took a position with the Pneumatic Tool Company as manager of the mining department, where he remained until his death, which occurred at Houghton, Michigan, on April 15.

JOHN M. SHERRERD

John M. Sherrerd was born at Scranton, Pa., on February 26, 1859. He graduated from Lafayette College in 1878 with high honors and, during the two following years, he took a course at the Columbia School of Mines.

After the completion of this course at Columbia, Mr. Sherrerd became chemist for Mr. Ario Pardee at Secaucus, N. J., for two years and then became connected with the Troy Steel and Iron Company where he remained thirteen years until the company went into the hands of a receiver. He was engaged in a number of capacities with this latter company, first as chief chemist, then metallurgist, and later ran the blast furnace.

In 1895, Mr. Sherrerd became connected with the Taylor Iron and Steel Company as General Sales Agent. At the time of his decease, he held the position of Assistant to the President of the Kennedy Stroh Corporation of Pittsburgh, Pa.

Mr. Sherrerd was a member of the following societies: The American Society of Civil Engineers, The American Institute of Mining Engineers, The American Society of Testing Materials, the Lake Superior Mining Institute, The National Geographical Society and the Engineers Club of New York. He died at his home in Easton, Pa., on April 16.

EDGAR H. MUMFORD

Edgar H. Mumford was born at Groton, Mass., on Sept. 20, 1862. He was graduated from Massachusetts Institute of Technology in 1886 in the Department of Mechanical Engineering.

In 1886, he entered the service of the Union Pacific Railroad at Omaha, Nebraska, in the motive power department and left there after promotion to the position of master mechanic of the Leavenworth Division, to become superintendent of Russell Wheel & Foundry Company, Detroit, in 1889. After three years in this position, he came east and became associated with Henry R. Worthington, Inc., Brooklyn, N. Y. Shortly afterward he was placed in charge of the new foundry built by this company at Elizabeth, N. J. Mr. Mumford left this position to become manager of the New York office of Bement, Miles & Company of Philadelphia, which he opened for them at that time. He remained in this position until the summer of 1895, when he started in business for himself. With Harris Tabor and Angus Sinclair, he purchased the business of the Tabor Manufacturing Company from Manning, Maxwell and Moore and remained with it as secretary and treasurer for ten years. In 1900, the Company's plant was moved to Philadelphia, and in 1905 he resigned from it to form the E. H. Mumford Company, builders of molding machines, of which he was president and treasurer. In 1909, he became vice-president and general manager of the Mumford Molding Machine Company, where he remained until shortly before his death, at which time he was arranging to enter the molding machine business under his own name.

Mr. Mumford was for twenty years an inventor and builder of molding machines known as "Mumford Machines," and was a recognized authority on them and an expert in their application to the foundry.

He was a member of the Engineers Club, the Machinery Club, Technology Club, and the Art Club of Philadelphia. He died at his home in Plainfield, N. J., on April 18.

GEORGE T. REISS

George T. Reiss was born in Cincinnati, Ohio, on December 6, 1849. He was educated in the common schools, supplemented by private instruction in drawing, designing and mechanical philosophy. In 1877, he became draftsman at

the old Cope and Maxwell shops in Cincinnati, but in 1878 he was placed in charge as a master machinist of the engineering department of the Niles Tool Works, which was moved from Cincinnati to Hamilton, Ohio, in 1871. He was chief mechanical engineer of the concern, later becoming superintendent of the drafting department and subsequently elected to the board of directors, of which he was also secretary. Later he became vice-president of the directorate, which position he held until the time of his death. Mr. Reiss died at his home in Hamilton on May 5.

FRED STARK PEARSON

Fred Stark Pearson, who lost his life on May 7 in the Lusitania disaster, was born July 3, 1861, in Lowell, Mass. He graduated from Tufts College in 1885 with the degree E.E. and received the degree of M.E. in 1886.

In the early part of his career, after leaving college, he held the positions of chemist for the Boston Butter Company, superintendent of the Blue Ridge Gold Mining Company in Virginia, mining expert surveying copper mines in Texas and gold deposits in Brazil, manager of the Somerville Electric Light Company, consulting engineer for the Woburn Electric Light Company, and for Chandler Electric Light Company in Halifax, consulting engineer for the American Aluminum Company and chief engineer in the steam and electric departments of the West End Street Railway Company in Boston.

His later enterprises, the result of his organization, may be classed as electric light and power companies, electric tramway companies, telephone companies, gas companies, steam railroads, irrigation and land companies, lumber manufacturing companies and mining and chemical companies. These companies were centered principally around the following cities: Mexico City, Mexico; Rio de Janeiro and Sao Paulo, Brazil; Barcelona, Spain; Toronto, Winnipeg and Niagara Falls, Canada; and El Paso and Juarez in Texas and Northwestern Mexico.

In steam railroads, the principal ones in which he was interested are the Mexico and Northwestern Railroad from Chihuahua to El Paso in the center of several million acres of timber and mining land which his companies own, and the Denver & Salt Lake Railroad, or Moffatt System, extending now from Denver to Steamboat Springs, but to be pushed through to Salt Lake City in the near future. The details of his numerous projects, however, were handled by his New York staff, a corporation called the Pearson Engineering Corporation, Ltd., in conjunction with the local staffs in each of the cities where his public utilities were located.

Dr. Pearson was a member of a large number of technical societies, among which were the following: American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Society of Naval Engineers, the Institute of Electrical Engineers (England); the American Institute of Mining Engineers, the American Electro Chemical Society, the New York Railroad Club and the American Forestry Association.

JOHN BIRKINBINE

John Birkinbine, whose death occurred in Cynwyd, Pa., on May 14, was born in Reading, Pa., on Nov. 16, 1844. His education was received at public schools and the Friends High School in Philadelphia, the Hill School at Pottstown, Pa., and the Polytechnic College of Pennsylvania. His

studies were interrupted by military service in 1863-4 on scout duty with the Union Army under two enlistments. Later, two years were devoted to practical work in a machine shop and subsequently he was associated with the late P. L. Weiner as the firm of Weiner and Birkinbine, which operated the Weiner Machine Works at Lebanon, Pa.

Much of his work has been in mining, metallurgy and blast furnace construction. As manager for the South Mountain Mining & Iron Company, he carried on experiments with various fuels for iron ore smelting while maintaining the furnace in constant operation. The carefully recorded results obtained were widely published and are referred to in text books by other metallurgists as being the most complete made.

From his Philadelphia office, he has been sent to nearly every state and to Canada and Mexico for examinations, reports, constructions of or improvements to iron ore mines, blast furnaces, iron works, water supplies, hydraulic developments, irrigation projects, etc., and his engineering knowledge has been requisitioned by several European corporations. A number of business trips were made to Mexico beginning with a visit to the Cerro de Mercado at Durango, Mexico, before railroads were established in that part of Mexico.

Mr. Birkinbine was probably the pioneer to suggest an iron industry at the head of the Great Lakes using coke made from Pennsylvania coal and his report was an important factor in establishing the iron industry at the head of Lake Superior; the blast furnace at West Duluth, Minn., was built under his supervision. He was engaged by the State of Texas to investigate the practicability of iron manufacture in the Lone Star State. As an engineer, he co-operated with Mr. E. S. Cook of Pottstown, Pa., who did much to advance the iron industry. He was for some years consulting engineer for the Philadelphia and Reading Coal and Iron Company, and held a similar position with Mr. Thomas A. Edison during the latter's early experiments on magnetic concentration of iron ore, and with Witherbee, Sherman and Company in beneficiation tests; also for the Colorado Fuel and Iron Company for the enlargement and improvement of their works and the construction of an augmented water supply system.

He has also acted as an expert for financial interests and for a number of the greatest corporations and several large railroads in this country. He was chief engineer, vice-president and chairman of the Committee of Awards of the National Export Exposition, served on Juries of Awards at the Centennial, World's Columbian, Pan American and Cotton States General Expositions, and was named for similar duties for others.

Since its inception in 1905, he has been chairman of the Water Supply Commission of Pennsylvania, and was active in forming the Pennsylvania Forestry Association. He was also active in the formation of and served as secretary to the United States Association of Charcoal Iron Workers and for nine years edited their journal. For many years, he was special agent for the United States Geological Survey, preparing the reports on iron ores for the 11th and 12th censuses and that on manganese ores for the 12th census. He was appointed by the Secretary of the Interior as expert metallurgical engineer for the Bureau of Mines.

During his career, Mr. Birkinbine has also maintained his

specialty in hydraulic engineering, acting as engineer on water supplies for various municipalities. He has not only witnessed, but has had active participation in the development of water power for electrical energy. While he was at college, electricity was a laboratory experiment only, and the use of water power was then confined to limited volumes at low heads for direct mechanical purposes; his activities have covered the development of hydro-electric science to its present advanced stage. In 1888, he prepared a comprehensive report on the development of the great water power of the St. Louis River in Minnesota, considering a fifteen mile transmission, though no water wheel manufacturers would guarantee turbines for heads above 35 feet.

For ten years, he served as president of the Franklin Institute in Philadelphia. He was also a member of the Engineers Club of New York, The American Society for Testing Materials, the Engineers Club of Philadelphia, of which he was president in 1893, the Manufacturers Club of Philadelphia, the Pennsylvania Foundrymen's Association, the George C. Meade Post I. G. A. R. of Philadelphia, an honorary member of the Canadian Mining Institute and a member of the Institute of Mining Engineers, of which he has been manager, vice-president and president.

PERSONALS

Carl Stenbol has accepted a position with the Anaconda Copper Mining Company, Anaconda, Mont., as mechanical engineer and designer.

Willis W. Jourdin, until recently chief engineer of the power division of the Chino Copper Company, Hurley, New Mexico, has been placed in charge of the power plant jointly owned by the Inspiration Consolidated Copper Company and The International Smelting Company at Miami, Arizona.

M. R. Hull who, for the past six years has been connected with the engineering department of the Anaconda Copper Mining Company, at Great Falls and Anaconda, Mont., has been appointed superintendent of construction at the Washoe Smelter at Anaconda.

J. Norman Bulkley, late consulting mechanical and electrical engineer to the General Mining and Finance Corporation, Ltd., London and Johannesburg, has opened a joint office with S. C. Thomson, in New York, for the practice of consulting engineering.

Horace R. Wentzell has severed his connection as superintendent of the Bourke Machine Company of Detroit, Mich., and has become affiliated in a similar capacity with the Houk Manufacturing Company of Buffalo, N. Y.

David Moffat Myers announces that he has consolidated his practice with that of John S. Griggs, Jr., an electrical engineer with offices at 110 West 40th St., New York. Mr. Myers was formerly mechanical engineer for the United States Leather Company but since 1906, he has had an office of his own at 17 Battery Place. He has specialized on the efficient operation and design of industrial plants with special reference to steam and fuel economy and to the use of exhaust steam in the production of high over-all efficiency.

Thomas A. Edison received the Civic Forum Medal of Honor for Distinguished Public Service on May 6, 1915. President Butler of Columbia University presided. The speakers of the evening were Com. G. Marconi, Charles P. Steinmetz, Richard C. Maclaurin, Charles A. Coffin and Percy Mackaye.

The following members of the Society were speakers at the annual banquet of the students of Sibley College of Engineering of Cornell University held on April 23: Calvin W. Rice, Secretary of the Society, Thomas E. Durban of the

Erie City Iron Works and Prof. D. S. Kimball of Cornell University.

On May 20, Mr. Harrington Emerson, one of the foremost efficiency engineers in the United States, addressed the Milwaukee Efficiency Society on The Natural Law of Organization.

STUDENT BRANCHES

Members of student branches are requested to notify the Secretary of any change in address as promptly as possible, in order to facilitate delivery of The Journal.

BROOKLYN POLYTECHNIC INSTITUTE

A regular meeting of the Brooklyn Polytechnic Institute Student Branch was held on April 17. Reports of the inspection trip, lasting ten days, which was held during the spring vacation, were given by W. A. Betts and H. A. Brandt. The trip included the cities of Cleveland, Detroit, Chicago, Cincinnati, Pittsburgh and Washington. The manufacturing plants visited were the Brown Hoisting Machinery Company and the new Pennsylvania ore docks in Cleveland, the Ford and Packard automobile plants in Detroit, the plants of the Illinois Steel Company, the By-Products Coke Company and the Pullman Palace Car Company in Chicago, the factory of the Proctor and Gamble Company in Cincinnati and the plants of the Westinghouse Machine Company, the Westinghouse Electric and Manufacturing Company and the American Bridge Company at Pittsburgh. The University of Cincinnati was also visited.

A meeting of this branch, which took the form of a convention, was held on May 1. The meeting of the afternoon was preceded by an inspection trip to Peter Doelger's Brewery in New York. At the afternoon session, Prof. W. D. Ennis spoke on The Progress of the Polytechnic Institute Student Section. He spoke of the practice which the members received in self-government by the participation in and conduction of the technical meetings. The scope and increased number of inspection trips and the large membership of the section were also mentioned. Herman Brandt, '16, gave an illustrated talk on The Una-Flow Engine, showing the history and development of this type of prime mover to date, and Prof. H. P. Hammond presented a paper on The Selection of Hydraulic Turbines, dwelling on the modern types of machines. He also gave a brief history of water wheels, and gave a short sketch of the men who were prominent in developing this type of prime mover.

In the evening, the annual dinner of the section was held in New York. The speakers were President F. W. Atkinson, Consulting Prof. George A. Orrok, Dr. M. C. Hilseng and Dr. J. B. Chittenden.

At this meeting, the following officers were elected: Herman Brandt, chairman; George L. Kay, vice-chairman; Charles E. Rohmann, secretary; Joseph L. Kopf, treasurer.

COLORADO AGRICULTURAL COLLEGE

At a meeting of the Colorado Agricultural College on March 10, D. R. Stephens gave an interesting talk on the tempering of high speed steels. The talk included details of the change in the structure and hardness, as well as temperature necessary. Methods of annealing tool steels were also touched upon.

S. L. Conrey gave a talk on the eight-cylinder Cadillac. After giving a short history of the development of eight-cylinder gas engines, he went into the details and advantages of the Cadillac automobile as equipped with the eight-cylinder power unit.

At a meeting of the branch on March 24, T. H. Sackett gave a talk on The Works of the Colorado Fuel and Iron Company in Pueblo. In the plant, the entire process of reducing the crude ore to iron and its subsequent transformation into rails, bolts, rods, nails, wire and other iron and steel products may be followed. Every effort is made there

to utilize all the gas from the blast furnaces, which is also used to produce steam for the power used on the grounds. Practically all the power used by the steel mills is generated in this way. This company has also a very complete machine shop and foundry, and makes a great portion of the machinery used by the mining industries of the state.

At the meeting held on April 30, Mr. Searles gave an interesting treatise on Mechanical Stokers. He followed the development of the mechanical stoker from the crude, early attempts of the inventor to the more or less successful types in use today. He concluded by mentioning the various means used to bank the fires when automatic stokers are used. E. Murray gave a very detailed description of the plant of the Denver Rock Drill Company, and emphasized the fact that this is one of the most progressive manufacturing plants in the west. It is equipped with very complete laboratories for testing the steel put into their sole product, the rock drill. As they produce but the one article they have been able to equip themselves in a very thorough manner. The shops are well managed and the workmen well protected. The machine shop is fitted with the most modern lathes, grinding machines, drill presses, etc. Besides making the ordinary post and jack-drills they are now putting out an electric drill.

CORNELL UNIVERSITY

A meeting of the Cornell University Student Branch was held on April 21. I. N. Knapp gave an illustrated talk on The Origin, Occurrence and Production of Petroleum and Natural Gas. He gave a general survey of the whole field of gas and oil production, touching on such phases of the subject as the different sorts of oil "sands," theories of the occurrence and origin of oil and gas methods of well-drilling and the control and extinguishing of oil and gas fires.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College on April 14, P. J. Freeman, a member of the engineering faculty and formerly mechanical engineer with the Gullett Gin Company of Aruite, Louisiana, addressed the student branch on The Mechanical Engineer in the Cotton Industry. The speaker discussed how this problem has been solved during the past century and outlined other problems which await the genius of the engineer. The speaker illustrated the problem which confronted the early growers by passing a sample of seed cotton among the members of the society and requesting them to separate the seed from the cotton fibre. The manufacture and operation of gin linter sand compresses were discussed and illustrated by means of sketches and lithographs.

C. A. Carter, a student member, gave a paper on Irrigation in Western Kansas. Mr. Carter gave a very interesting discussion on the problems of the irrigation in the western part of the state, particularly in the Arkansas Valley.

LEHIGH UNIVERSITY

At a meeting of the Lehigh University Branch on April 9, L. Mardaga spoke on Diesel Oil Engines and R. C. H. Heck on Speed-Reducing Gear Chains.

On May 13, the following officers were elected: C. H. Shuttler, president; W. C. Hartman, secretary; C. H. Thomas, treasurer, and G. B. Adams, librarian.

Professor Butterfield spoke on Municipal Engineering.

LELAND STANFORD UNIVERSITY

At the regular meeting of the Leland Stanford University held on April 27, the following officers were elected for the first semester, 1915-1916: W. H. Warren, chairman; H. F. Elliot, vice-chairman, and F. G. Hampton, secretary-treasurer. Dr. Durand was recommended to the President of The Am.Soc.M.E. for the office of honorary chairman.

Mr. Stebbins of the Engineering Faculty gave an interesting talk on his experience in Locomotive Testing.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

The annual banquet of the Massachusetts Institute of Technology Student Branch was held on April 29. The attendance at the dinner was the largest in the history of the Society, 102 being present as against 65 the year before.

At this meeting the following officers were elected for the ensuing year: K. C. Richmond, chairman; P. Y. Loo, vice-chairman; C. E. Shedd, secretary; J. W. Stafford, treasurer, and G. W. Tuttle, R. M. Snyder and E. W. Rounds to comprise the governing board.

The speakers of the evening were Howard Elliott, president of the New York, New Haven and Hartford Railroad; Albert B. Tenney of the C. H. Tenney Electric Company, Prof. H. W. Hayward and Prof. E. F. Miller.

PENNSYLVANIA STATE COLLEGE

A joint meeting of the engineering societies at the initiative of the A.S.M.E. Section of the Pennsylvania Student Branch was held on April 16. The purpose was to insure a closer relationship among the engineering students. President Garman of the mechanical engineering section presided at the meeting. Prof. E. D. Walker, dean of the engineering school, and Prof. J. A. Moyer of the A.S.M.E., spoke on Engineering and the Fellowship of Pennsylvania State College Engineers.

At a meeting of the Branch on April 30, C. F. Kennedy spoke On Mines and Mine Problems. He spoke of the general features of the mine and described in detail the collieries, breakers, hoisting engines, boiler plants and various electrical apparatus. The problems of efficiency and repairing were then discussed and intensified by the speaker's practical experience.

PURDUE UNIVERSITY

A meeting of Purdue University Student Branch was held on April 27. Jack Abbott, superintendent of the Lafayette City Street Railways of the Fort Wayne Northern Indiana Traction Company, spoke on The History and Comparisons of the Power Units in Use in the Lafayette Plant. After giving a brief history of reciprocating engines and steam turbines, the speaker gave the history of the plant. Not many years ago, in 1906, the middle west conceived the idea of interurban roads. To accomplish this, it was necessary to combine a number of city street car systems and to build connecting lines from city to city, touching as many small towns as possible and obtaining local passenger and freight traffic. Upon combining all the local systems, it fell to the lot of the engineer to use the engines, turbines, boilers, and other auxiliary apparatus found in the several power houses and to concentrate the best in one central station. The Lafayette station under the above conditions contains a representative of all makes and kinds of apparatus. In its day it would have been pointed out as a modern and up-to-date station.

In the plant, the coal is handled directly over storage bins on an elevated track and unloaded from dump bottom cars. It is then taken from the storage bins through an underground tunnel in which there is a narrow gauge track into a small coal car and transported by steam elevator to overhead bunkers, which are connected to hoppers in front of the boilers by down spouts that feed the coal to chain grate stokers.

The boiler room consists of two 500 h.p. boilers and four 350 h.p. boilers giving in all approximately 2500 h.p. nominal rating.

The principal driving units consist of the following: one cross-compound engine direct connected to 500 kw., 3 phase, 380 volt, 25 cycle generator; one tandem compound engine direct connected to 500 kw., 3 phase, 380 volt, 25 cycle generator; one 400 kw., 3 phase, 380 volt, 1500 r.p.m. Westinghouse Impact Reaction Turbine; one 500 kw., 2 phase, 2200 volt, 60 cycle, 3600 r.p.m. Westinghouse-Parsons turbine. Three of these units are equipped with barometric condensers and the other, the cross-compound, with a surface condenser. The condenser pumps are long stroke, slow speed.

To make a comparison of these particular units, that is, a small turbine in its infancy, with Corliss engines that have for a number of years been up to their greatest efficiency would not be fair. The engines have been giving the best efficiency. Operating at full load, 26 in. vacuum 150 lb. gauge pressure, no superheat, the 500 kw. turbine used 22.6 lb. of steam per kw.-hr. and the 400 kw. turbine, 26.5 lb. On

the other hand, the cross-compound, operating under similar conditions except that steam contained 2 per cent moisture, used 14.3 lb. of steam per i.h.p. and the tandem compound 13.5 lb.

UNIVERSITY OF CINCINNATI

At a meeting of the University of Cincinnati Student Branch on April 9, Mr. L. C. Morrow of the Lodge and Shipley Company gave a talk on Time Setting in a Car Shop. Mr. Morrow pointed out that the conditions which prevail in a car shop differ greatly from those of other manufacturing plants. The machines are more easily operated, the work is rougher, and the employees are for the most part unskilled. Also the weather and the seasons of the year affect the car shop men. The shops are practically open, and, in the winter, the lubricating oil freezes and other elements of like nature cause delay. The main fact, however, that the weather is cold causes the men to work steadily, and perhaps harder than in summer.

In setting the time for a particular job, the operations are broken down to their elementary movements. For example, if the operation was one of a small punch press, the movements would be something like this: Take from pile to machine, place in position, press the foot pedal, remove the work and place on finished pile. The individual movements would then be timed by means of a stop watch. With this data in hand, the final time limit would depend on such variables as number of pieces, importance of operation, materials used, interruptions by foremen or others and time for lunch. Then having taken the above into consideration, it is wise to allow a sufficient margin, which, in most cases, is 20 per cent. The speaker showed that in some kinds of work considerable time must be allowed for recuperation. Mr. Morrow concluded his talk by discussing the attitude of the employee towards the time setter. He also gave some suggestions as to the best method of getting results, and related some of his experiences.

UNIVERSITY OF COLORADO

A meeting of the University of Colorado Student Branch was held on April 22, at which Charles W. Comstock, former state engineer, spoke on The Engineer in the Business World. During the talk, he pointed out what an engineer is or should be and advocated more thorough courses in English, history, political economy and logic in addition to the technical subjects and in place of the so called practical work, a large part of which might much better be left to be obtained outside of school. The need of preparation for the strictly "business side" of an engineer was further emphasized by the statement that engineering plans are often vetoed by boards of directors not because of some error in design or estimate, but because of the poor business aspect as seen by men in the commercial world.

UNIVERSITY OF MINNESOTA

An open meeting of the University of Minnesota Student Branch was held on April 15. A set of five films showed very completely the important and interesting features of the manufacture of Maxwell Motor Cars. They began with the reduction of the iron from the ore and passed through the manufacture and testing methods to the shipment and selling of the cars. The series was concluded with a tour through some very beautiful mountain country, during which the car was made successfully to mount some very steep grades.

UNIVERSITY OF MISSOURI

A meeting of the University of Missouri Student Branch was held on April 22. Prof. A. L. Westcott read a paper on Boiler Practice in St. Louis. The paper was largely an account of many tests performed by the author in the service of St. Louis Water Works system, which consists of three high service stations and one low service station. The purpose of the various tests was the reduction of the coal consumption, which was about 60,000 tons per year.

The Hawley down draft hand-fired furnace is very popular there, as it is more nearly smokeless than any other hand fired furnace. The boilers at the Baden Station were

equipped with steam flow meters to determine the rate of evaporation. It was found that the rate of evaporation varied very greatly. This was due to the poor use, or rather non-control of the draft by the furnace. The non use of draft control by the furnace is due largely to the fact that dampers are unhandsly arranged with respect to the firing floor. Shaft gauges and CO₂ recorders were installed so that readings could be taken from various parts of the furnace. Besides being valuable for determining conditions of combustion, the recorders are very useful in detecting air losses in furnace settings. In some old furnaces, these air losses reach 120 per cent. The method of detecting these "air leaks" with a CO₂ recorder is simple. The per cent of CO₂ is read as gases leave the boiler and also as they leave the furnace. The change in per cent of CO₂ shows how much air has leaked in through the setting. The best remedy for these air leaks is a sheet metal covering over the entire setting.

Poor boiler efficiency is due to excess air more than any other one thing. Excess air is due to fires of uneven thickness and its coming through thin spots in fire; also to holes in the fuel bed which allow larger quantities of air to pass through. This may be due to lumpy coal—good boiler practice allows no large lumps to be fired; dirty fires, where there is an accumulation of clinkers and ash, as the clinkers shut off air and allow poor mixture of gases; and excessive draft. At all times the draft should be proportional to the thickness and density of fire.

UNIVERSITY OF WISCONSIN

At a meeting of the University of Wisconsin Student Branch on March 25, the following officers were elected: J. B. Wilkinson, president; F. T. Goes, vice-president; W. D. Harvey, treasurer, and G. C. Richardson, secretary.

At a meeting on April 8, S. I. Roth gave a paper on The Buckeyemobile.

On April 22, Fred T. Goes read a very interesting illustrated paper on the Gate City Precooling Company. This plant was installed in 1910 at San Bernardino, California, for the purpose of the precooling of freight cars before their journey to the east. The capacity of the plant is 150 cars per day. The precooled air is blown in at one end of the car from the pre-cooler by a sirocco fan, and the warmer air is drawn from the other end of the car by another sirocco fan, thence into the pre-cooler chamber, cooled and blown into the car, continuing this path until the car is cooled to a temperature of 40 deg. Fahr. The incoming temperature is 8 deg. Fahr., and the air which leaves the car is at a temperature of 29 deg. Fahr. As the suction pressure and inflowing pressure are equal, the middle of the car is kept at atmospheric pressure. The advantages are many, for the preloading of goods to and from storage is avoided, and the time schedule between producer and market is shortened.

WASHINGTON UNIVERSITY

At a meeting of Washington University on April 21, R. H. Tait of the Tait-Nordmeyer Engineering Company gave a general talk on Refrigeration. The speaker discussed the different designs of compressors, spherical and flat cylinder heads, single and double acting. He described the troubles with packing and varying clearance caused by change in temperature in the compressor. The different systems of ice making and refrigeration were explained. Air machines, vacuum machines, semi-flooded, flooded and expansion ammonia systems, block ice, plate ice and can ice methods were dealt with.

The cost of ice plants is about \$1000 per ton capacity for plants of 30-50 ton capacity. The cost increases for larger capacities and decreases somewhat for smaller. The St. Louis Refrigeration Company has the largest ammonia transmission system in the world. They make ice and sell refrigeration to various users throughout the city. In a test made recently in that company's plant by Washington University students, their output was found to be 18 lb. of ice per ton of coal used. The Anheuser-Busch Company of this city has the largest ice plant in the world for making block ice.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 18th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer.

In sending applications stamps should be enclosed for forwarding.

0104 Young engineer for efficiency department of Indiana concern. Preferably young technical graduate, alert, teachable, practical, with good clear thinking head.

0106 Superintendent for plant employing about 150, in the manufacture of motors, transformers and auxiliary apparatus. Location, Canada.

0108 Head superintendent for large European concern, engaged in the manufacture of rubber shoes, technical and surgical articles, covering for rollers, tubes of all kinds, balls, toys and articles to be made of hard or other rubber, etc. Applicant must be thoroughly posted in this kind of manufacture. Foreman also wanted for these branches. Apply by letter. Name confidential.

0113 Designing draftsman, experienced on marine boilers, engines and boats. Good opening for young technical graduate. State age, experience in detail and salary expected.

0114 Shop engineer, with at least five or six years' experience in heavy and light forge work, structural, steam and electrical engineering and efficiency methods of handling material throughout the shop; also manufacture of wood and steel freight and passenger cars, electric cars and general work of similar character. Must combine practical shop knowledge with technical education; capable of handling costs and piece work, estimating, etc., with other duties. Location, Canada.

0119 Engineer with experience in testing of steam and electrical apparatus and in the operation of steam power plants. Location, Delaware.

0123 Man with four or five years' experience in designing and construction of electrical cranes, to act as draftsman and designer. Location, Canada.

0124 Works manager for plant devoted entirely to the manufacture of shrapnel shells, having approximately one hundred machine tools and, in addition, a large furnace capacity. Prefer man with experience in this line, with ability to organize quickly a new force of several hundred men. Must be well versed in machining, heat treating and furnace methods. Name strictly confidential. Apply by letter.

0129 Chief draftsman for manufacturing plant in Philadelphia. State experience, references, salary, etc.

0130 Large concern in middle west making lubricators, valves, heating specialties, carburetors, etc., desires a technical graduate with three to five years' experience, competent to follow the entire products of the company through their evolution, design and manufacture. Applicant would be required to supervise and coordinate the work of the various departments. Complete experience in this line of manufacture is not necessary, but knowledge of mill construction and maintenance would be useful. Salary depends upon qualifications.

0134 Professor of mechanical engineering. Applications will be received to July first. Prefer man of Canadian birth. Salary, \$2500; session seven months. Location, Canada.

0135 Young mechanical engineer wanted who has had an excellent technical training and a year or so of good practical experience; of good character and ability; or recent graduate willing to start at low salary. Apply through Society. Location, Massachusetts.

0136 Good opportunity for first class designer; a man with chiefly drawing office experience is needed, particularly on heavy machine tools and similar machinery. Location, Pennsylvania.

0139 Machine shop foreman for engineers, foundries, machinists, manufacturing sheet and structural steel, elevating and conveying machinery and ice tools. The position pays fifty cents an hour for an eight or ten hour day. New York State.

0140 Engineer or designer and draftsman in the hydraulic press line. Man experienced in hydraulics capable of making designs and drawings for special presses such as veneer, binder board, hot plate presses, etc. Location, Pennsylvania.

0143 Chemist with two or three years experience in research and industrial chemistry; for position dealing particularly along line of paints, enamels, metal coatings and work of similar character. Location, New York.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated except upon special request. Names and records are kept on the office list three months, and if desired must be renewed at the end of such period.

F-123 Industrial engineer with broad experience as consulting engineer and efficiency expert in machine shops, foundries, paper mills, etc., desires position as general manager or works manager. Would be interested in position where results would lead to business opening in firm.

F-124 Member, age 35, graduate M.E., Lehigh University, 14 years engineering experience in work requiring executive ability and tact in handling men, well qualified by training and experience to manage concern requiring broad engineering knowledge, mechanical, electrical and mining, and also ability to organize. At present engaged as general manager of coal mining company abroad. Is planning trip to Panama Fair in June or July, and can arrange interview en route from New York to San Francisco.

F-125 Junior member, mechanical graduate 1907, experienced in advertising and publication work, is open for position as publicity agent or advertising manager. Moderate salary at beginning if position is desirable otherwise.

F-126 Member, A.S.M.E. and Institution of Mechanical Engineers, with wide experience in all technical and commercial work, and in the American, European and Japanese markets, 16 years with exporters and importers of machinery, in charge of technical department in London and Tokyo, desires responsible situation in similar capacity. Familiar with English, German, French correspondence, and some Spanish.

F-127 Member, specializing in the installation of scientific management, expects to be at liberty from June first to December first, and desires engagements in this line during that time. Speaks Spanish fluently, and would accept engagements in Latin America for the investigation of the efficiency and possibilities of improvement of enterprises, or would undertake betterment work. If it should be desired that any temporary appointment become permanent, that could be arranged.

F-128 Associate-Member, graduate M.E., three years teaching and two of practical experience as assistant superintendent of small factory, has executive ability and capable of handling men, understands efficiency and cost keeping methods, will consider teaching or practical opportunity; willing to start on low salary in position of opportunity.

F-129 Junior member, graduate M.E., University of Wisconsin, five years experience in gasoline and kerosene, marine and farm engine design, including jigs, tools and special equipment. Engaged for six months at 750 kw. power plant, designing piping systems and general equipment. During last year and a half has been in charge of mechanical end of new cereal business. Will consider any good opening which may lead to executive position. Location immaterial.

F-130 Associate-Member, graduate M.E., Lehigh University, age 30, married, seven years experience designing, inspecting, erecting, selling and superintending in steam turbines, steel, pumps and waterworks specialties, desires responsible position where good character, personality, ability and application are assets.

F-131 Author of paper at Buffalo meeting desires responsible position; interview can be arranged there.

F-132 Associate-Member, age 32, with successful sales record, desires to become associated as sales engineer with manufacturer, preferably in the Middle West, or will open office as sales representative on commission if reasonable guarantees are made. Wide acquaintance with Chicago architects and engineers. At present employed.

F-133 Member, Stevens graduate, many years practical and teaching experience, desires position as professor of mechanical engineering. At present head of department in state college.

F-134 Junior, graduate M.E., Lehigh University, several years experience as draftsman, chief engineer's assistant, foreman and manager, at present located in prominent technical institution in New York, desires summer position which would afford experience in the mechanical field. Salary and location immaterial.

F-135 Mechanical and electrical engineer, 14 years varied experience with leading concerns in the design, manufacture, operation and maintenance of gas engines, oil engines and gas producers, testing and experimental work. Familiar with the construction and operation of large gas and steam electric power plants, pumping station, etc. Good organizer with executive ability and successful in handling men, desires responsible position with manufacturing concern or as chief engineer or general superintendent of large power system for the production and distribution of power.

F-136 Student member, age 23, graduate M.E., 1915, University of Minnesota, three months experience as draftsman in heating, ventilating and power design, desires position which offers opportunity for advancement.

F-137 Manufacturing superintendent familiar with the most efficient methods in machine shop, press work and assembling; good organizer and thorough systematizer, who can turn out production on schedule time, desires position. At present in automobile line.

F-138 Railway mechanical engineer, technical graduate with 16 years railroad experience as machinist, motive power draftsman and mechanical engineer, desires similar position, or one as mechanical inspector, assistant superintendent motive power or motive power assistant to general manager. Location immaterial.

F-139 Member, technical graduate, age 37, ten years wide experience in designing, engineering, production and accounting lines in manufacturing steam, gasoline and automobile engines and light and heavy machinery; also two years consulting and betterment work in factories handling similar products. Would negotiate with engineers and accountants. Location Middle West, preferably Detroit.

F-140 Mechanical engineer with broad experience in design and construction of water tube boilers and general plate work, also designing, estimating, purchasing and assistant manager, energetic and good organizer, desires responsible position with growing concern in Middle West.

F-141 Graduate M.E., four years manufacturing and designing experience, will leave present position to obtain sales training. Salary secondary.

F-142 Associate-Member, 13 years experience in operating and superintending power plants. At present holding responsible position as chief engineer of several plants, desires similar position with greater opportunity for advancement.

F-143 Mechanical engineer with 11 years experience in shop, office and field, desires to improve his conditions.

F-144 Member, age 42, graduate of Stevens Institute of Technology, 1893, with 15 years general experience, from draftsman up through executive management, followed by seven years specializing in organization and efficiency work in both manufacturing and commercial ends in a wide variety of lines, including machine shop, manufacture of chocolate, underwear, wholesale news distribution, brass goods, foundry, paper boxes, printing and publishing, desires a permanent connection with a progressive concern, location preferred, New York or vicinity. Will invest if conditions are favorable.

F-145 Junior member, age 27, Stevens graduate, class of 1911, possesses initiative and unusual mathematical ability, with four years experience in experimental, plant and executive work, desires change. Employed in Middle West, but coming to New York about July 10th.

F-146 Mechanical engineer, age 26, unmarried, graduate of middle western university, several years experience in field and office, is open for position, preferably in construction work. Location immaterial.

F-147 Mechanical engineer, age 30, married, technically educated, 12 years practical experience with large concerns as chief draftsman, and mechanic for valves, engineering specialties, tools, automobile and special machinery, mechanical write-ups, power plant design, installations and experimenting.

F-148 Associate-Member, age 31, technical education, journeyman machinist, first class draftsman, ten years experience in shop, drawing room, testing and designing tools for manufacturing of small interchangeable parts, wants to get into similar line. Ability to handle men. Location immaterial; salary secondary to opportunity.

F-149 Sales engineer, age 30, married, wide acquaintance in the southeastern states, experienced in handling steam, gas, hydraulic and electrical equipment for largest builder in America, wishes to locate permanently in his native South in capacity of district manager, or sales agent for similar or allied lines. At present employed, but desires change for personal reasons.

F-150 Member, Cornell graduate, age 38, married, nine and one half years experience in railroad shop, testing laboratory, drafting, supervision of power plant and foreman; two years construction work, design and installation of equipment in steel mills, desires position in mechanical department of railroad, manufacturing concern or firm of engineers.

F-151 Member, age 34, technical education, married, with broad experience with leading engineers in the East on design of steam power plants, heating and fire protection systems and inspection of mill and power plant construction and equipment, desires position with large manufacturing concern; at present employed as superintendent of construction on large mill and power plant.

F-152 Technical graduate, three years experience in construction work and repair, desires to get in touch with a master mechanic or chief engineer of large industrial plant or power company. Ability to handle men. At present employed.

F-153 Associate-Member, M.E. Case School of Applied Science, age 32, married, four years experience in engineering sales work, two years designing and installation of heating and ventilating equipment for industrial plants; has travelled in Cuba and South America, desires position with manufacturing or engineering concern. Will consider very reasonable salary till ability is proven. Location middle west, preferred, but will go elsewhere for real opportunity.

F-154 Student member, 1914, M.E., graduate of Lehigh University, some machine shop and foundry experience; at

present employed as instructor of mechanical drawing, desires position.

F-155 Member, technical graduate, age 32, having two capable associates and office centrally located in Philadelphia, solicits representation for reputable manufacturer who now has some trade in Philadelphia, but has at present no direct representation. The character of the product must be such that a considerable business will be possible as a result of thorough and systematic engineering salesmanship.

F-156 Member, age 33, married, Cornell graduate, 12 years experience in manufacturing, engineering and selling, desires executive position in small city involving little or no traveling. At present machinery sales manager in Chicago for large corporation. Present salary \$300.

F-157 Member, graduate Massachusetts Institute of Technology, age 36, 12 years successful experience as works manager or superintendent; thoroughly practical as well as technical. Managerial experience includes foundries, pattern shops, machine shops, erecting, sheet-metal stamping, electro-plating, lacquering, lithographing, miscellaneous machinery, power plant management, plant construction and equipment. Familiar with modern factory, and has handled from 1000 to 1500 men, desires position as works manager or superintendent.

F-158 Junior member, 1914 graduate, desires a position with a company specializing in the design of manufacturing plants.

F-159 Member, 20 years valuable and complete experience in design and construction of printers and allied trades machinery, desires engineering or executive position where this experience will be of advantage. At present employed.

F-160 Junior, age 38, sales engineer, broad experience in handling high grade mechanical specialties, large acquaintance with mill supply and machinery trade, desires to represent manufacturer in East or Middle West in capacity of district sales manager.

F-161 Technical graduate, two years shop and testing and seven years experience in teaching mechanical engineering subjects, desires position in university or technical school.

F-162 Member, graduate M.E., married, experienced in the management of the power and mechanical departments of industrial plants, and the mechanical departments of railroads; also wide and varied experience in sales and purchasing. Capable of managing coal mining property or plant manufacturing machinery. Prefer representing manufacturers of railway supplies or heavy machinery.

F-163 Member, age 39, married, with broad and thorough manufacturing experience from apprentice to agency manager in a large engineering corporation manufacturing steam and producer gas engines, producers and transmission machinery; with firm for nine years in the capacity of draftsman, designer, estimator, mechanical engineer, salesman and agency manager, also experienced in efficiency engineering, correspondent and advertising, desires position.

F-164 Graduate of Stevens, age 32, chief engineer of firm of industrial engineers, now completing construction and equipment of large manufacturing plant in South, entirely capable of general supervision of such contracts, investigating and developing prospects, as well as of preparing plans and specifications and superintending construction of any type of building, with power generation and distribution, etc., seeks new engagement. Location and salary no difficulty.

F-165 Junior member, M.I.T. graduate, age 27, married, four and one half years experience, including drafting, power plant, textile machinery, office and executive work, desires permanent position with reliable concern offering chance for advancement.

F-166 Student member, technical graduate E.E. of co-operative course, University of Cincinnati, five years practical experience in large western ice-machine and electric company. Experience embraces jig and fixture design, analysis of production costs, estimating, d.e. electric design and practical machine shop work, desires employment with engineering or manufacturing company, preferably as assistant to works manager or superintendent. At present employed. Salary secondary consideration.

F-167 Technical graduate in mechanical engineering, age 26, two years experience as mechanical draftsman in the designing and planning department of the Panama Canal, thoroughly familiar with railway equipment, dredging and excavating machinery, desires outdoor position with irrigation or power development company. Location preferred Pacific Coast or Rocky Mountain states. Present salary \$1500.

F-168 Member wishes to arrange for the manufacture and marketing of an improved type of shop appliance for which there is a constantly increasing demand at a good profit.

F-169 Junior member, technical graduate, married, traffic engineer of large company manufacturing motor trucks, desires similar position with one of the best makers of trucks, located either in Buffalo, Cleveland or Detroit. By co-ordinating the efforts of sales manager, assistant manager and traffic engineer, the effective results of dealer, branch house or traveling salesman can be materially increased and a plan for effecting the installation of motor trucks where horses are now used, or for increasing sales, can be realized.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

ANNUAL MEETING IN DECEMBER 1915

THE Annual Meeting of the Society will be held in New York, December 7-10. Although complete plans for the meeting have not been formulated as yet, several committees have announced their intention of holding sessions, among which are a session by the sub-committee on Railroads devoted to a discussion of Trucks for Passenger Coaches, one by the Textile Committee and another by the committee on Machine Shop Practice. The committee on Industrial Buildings will present a paper on the subject of Foundations, and the committee on Air Machinery is endeavoring to arrange for a session. *It is urged that all papers for the Annual Meeting be sent to the Secretary not later than September 1, and that those who contemplate contributing papers notify the Secretary in advance of this date if possible.*

THE SPRING MEETING

THE Spring Meeting of the Society at Buffalo, N. Y., the first meeting of the Society to be held in Buffalo, was a decided success. The meeting opened on Tuesday, June 22, and closed on Friday, June 25, with headquarters at Hotel Statler. There were 223 members registered and 201 guests, a total attendance of 424, and the figures would probably have gone even higher had it not been for the unexpectedly cold weather on Wednesday. On Thursday a party of fifty came from Cleveland by boat.

The local committees had made most complete, and even elaborate, preparations for the reception of the guests. During the time of the meeting many of the committee members were in constant attendance, and nothing was left undone that could in any way contribute to the pleasure of those who were present. The chairmen of the several local committees were the following: General Committee, David Bell; Finance Committee, D. W. Sowers; Reception Committee, H. P. Parrock; Entertainment Committee, David C. Howard; Women's Committee, Mrs. William Henry Barr; Hotel Committee, W. H. Carrier; Printing and Publicity Committee, John Younger.

A great deal of interest was shown in the technical excursions to industrial plants in Buffalo, many of which opened their doors freely to the visitors. Niagara also contributed its share of interesting features, and the Reception, Entertainment and Women's Committees were at all times ready to provide some form of entertainment. In spite of these many social attractions, however, the meeting was very obviously one of serious purpose where attendance at professional sessions and consideration of committee activities were made matters of the first importance.

There were four professional sessions arranged by the Committee on Meetings, John H. Barr, Chairman. These were held in the ball room and a private dining room of the hotel, except on Wednesday morning, when all went to Niagara Falls for the day, and met for the business meeting and a professional session in the auditorium of the Shredded Wheat Company's factory.

Four important committee meetings were held during the convention, as follows: the Research Commit-

tee, the Local Sections Committee, the Boiler Code Committee, and the Increase of Membership Committee. The Local Sections Committee was well represented by delegates from the local sections in all parts of the country, and three sessions were held. Similarly, the Boiler Code Committee and the Increase of Membership Committee held important meetings of two sessions each. Accounts of these meetings appear elsewhere in this issue.

The headquarters were opened in the hotel for registration at 2 o'clock on Tuesday. Many took early advantage of this, and the registration on the first day amounted to over 150. At 4 o'clock a meeting of the Research Committee was held, and at 6 o'clock a conference and dinner of officers and representatives of local sections, with the Local Sections Committee. This dinner proved to be of considerable importance in connection with the development of their work.

TUESDAY EVENING'S RECEPTION

On Tuesday evening, the party gathered in the ball room of the Hotel Statler for the informal reception by the members of the Engineering Society of Buffalo and local members of The American Society of Mechanical Engineers. Chairman David Bell, of the local committee, opened the exercises by introducing Mr. Frank B. Baird of Buffalo, who warmly welcomed the engineering guests. He said in part:

Before formally welcoming our visitors, let us ask Who are these people and why welcome them? Our visitors are a clan of dreamers whose dreams come true. They study to control those wonderful forces of nature which have attracted man for ages. First viewed with awe and superstition, these forces were afterwards studied in that process of evolution which is thousands of years old and still in its infancy.

Primitive man, sensing that he could drag a larger load than he could carry, built a sled in a cold climate, rollers in a warmer climate. Then came the first mechanical engineer, the man who first used the wheel and axle. We do not know his color, his skull long is dust, but his idea lives in the principle of locomotion. Were he here today he would be greeted as a hero.

The speaker referred to Jules Verne, the Frenchman who wished to be an engineer but was forced instead to be a

lawyer, yet who dreamed of conquering the forces of nature. Some things in his stories, designed to make them attractive, should be excused; but now, fifty years after they were written, his dreams are coming true. He referred also to John Fritz, the great mechanical engineer, who, when steel shafts of greater strength were demanded conceived and built the hollow axle.

He told of Dr. Brashear's remarkable astronomical instruments. The naked eye counts eight to twelve stars within the ten-degree angle of the lens used in stellar photography but the photograph itself, less than one foot square, will divulge more than 200,000 stars. We are only on the threshold of research, the benefits of which will come to us and our children. It is hard to conceive of the vastness of the dreams of the mechanical engineer. Hundreds of broad gauge men are at work on the problems of nature and science. These are the type of people we are to welcome and Buffalo is proud to receive them.

REMARKS BY PRESIDENT BRASHEAR

Dr. John A. Brashear responded for the Society, beginning his remarks with an observation on the general ignorance of the wonders accomplished in the engineering world, and told, to illustrate this, to the meriment of the audience, some stories of the astonishment among the negroes of the South at the time of the Atlanta expedition to observe the eclipse of 1900.

To illustrate the remarkable advances in science and engineering, Dr. Brashear said:

I have talked with the woman who sat for the first photograph ever made in America. She was 84 years old when I knew her. The photograph was taken the year before I was born, 1839. The photograph was a daguerrotype. She had to sit still in a chair for an hour with her face covered with white powder and her eyes closed. Three great mirrors on the roof of a building were throwing light on her all the time. The picture was perfect. Today the same result is achieved in a tenth of a second.

He further continued: I have an apparatus in Pittsburgh which photographs and records the actual flight of a cannon ball or a shell from the mouth of a cannon. It will record that flight for a foot or for a mile. By that means, we determine accurately the speed of the projectile and the vibrations of the gun itself, as high as 455 vibrations a second.

I had the happy privilege of working with Professor Langley. I knew all the little flying machines with which he experimented. I saw the great model with which he had planned the first successful flight. The world said it was a failure and Langley, my good friend, died of a broken heart. Don't think that these engineers, these dreamers of great dreams that come true to benefit all mankind, have happy lives! The tragedy of Langley came to me a few years ago when I was sailing 2,000 feet above the sea in California in a flying machine.

There are on my list 180 names of men who have done something to make the world go round more smoothly on its axis, he said, and their unvarying characteristic is simplicity. The great man is the simple man who can get down and find out the reason of things.

But where will the credit for these achievements go finally? I say to the mothers, the sisters and the wives of the

scientists. They bear the hard struggles; they know the pains of the achievement; they inspire. For five years Mrs. Brashear and I labored together in our little shop on the hillside in Pittsburgh making the first astronomical lens in America. I was working in the daytime, ten hours a day in the rolling mill. Nights my wife and I worked together. The critical moment of success had come. We went to our shop together that night so happy. Five years of work was to be finished. There was an accident. The lens was broken, the telescope ruined.

How I worked the next day I do not know. I was heart-broken, dulled, stupefied with grief. But up in the cottage on the hill a brave woman had gone smilingly to work. When I got home that night there was a fine supper; in the shop a new disc had been set up, the machines all made ready. And, inspired and cheered, we worked and in two months more the work of five years was regained.

Following the addresses a social hour was spent, when an elaborate buffet luncheon was served by the hosts of the evening, after which there was dancing.

WEDNESDAY AT NIAGARA FALLS

Special cars were ready at the Hotel Statler on Wednesday morning for the day's outing at Niagara Falls. One hundred and fifty joined in the trip, arriving at the Shredded Wheat Company's factory at Niagara Falls where the business session and the professional session which followed were held. Simultaneous with these was a conference of the representatives of local sections and the Local Sections Committee.

At the business session, the report was announced of the tellers on the amendment to C-45 of the Constitution. There were 1182 votes cast: 1135 for the amendment, 5 against, and 42 defective. The effect of this amendment is to add to the list of standing committees a new Committee on Standardization.

Announcement was made of proposed amendments to C-48 and C-54 of the Constitution. The first relates to a special nominating committee and specifies:

C-48. Any group forming one per cent of the persons entitled to vote may constitute itself a Special Nominating Committee, with the same powers as the Annual Nominating Committee appointed by the President.

The second proposed amendment relates to the copy-righting of reports and papers and reads as follows:

C-54. The Society shall claim the exclusive copyright to any reports of its duly appointed committees. The Council shall waive such copyright for specific reports. The Society shall copyright all papers read before the Society, printing thereon in each instance that the paper may be reprinted by anyone after the same has been read before the Society, provided that due credit be acknowledged to the Society and the author. The policy of the Society shall be to give the professional and scientific papers read before it the widest circulation possible, with the view of making the work of the Society known, encouraging engineering progress and extending the professional reputation of its members.

The Secretary presented that portion of the report of the Committee on Special Threads for Fixtures and Fittings covering rolled thread screw shells, together

with a letter from T. C. Martin, Secretary of the National Electric Light Association, which contained the approval of the Chairman of their Lamp Committee and Committee on Wiring of Existing Buildings, of the N. E. L. A. It was voted that the report be received and printed in the usual way.

The balance of the morning after the transactions of the Society's business was devoted to the discussion of professional papers.

A number of the visitors took advantage of the opportunity to inspect the Shredded Wheat Company's plant, and at one o'clock those who had been attending the meeting, and the ladies who had accompanied the party and who had spent the morning in the enjoyment of the attractions of Niagara Falls, gathered for luncheon at the International Hotel. After luncheon, the group was photographed and then the party was divided into sections for the gorge trip, and for inspecting the power plants of Niagara.

LECTURE BY DR. F. H. NEWELL

An entertaining lecture was given on Wednesday evening by Dr. F. H. Newell, of the University of Illinois and formerly Chief of the U. S. Reclamation Service. The subject was The Engineer as a Citizen, and beautifully colored lantern slides were used of striking views of the reclamation work. An abstract of the lecture is given elsewhere.

PROFESSIONAL SESSIONS

On Thursday morning there were two simultaneous sessions and a concluding session on Friday morning. Fourteen papers were presented in all, several of which were highly technical in character, and drew out a thoughtful and strong discussion. The sessions were well attended, particularly the one on Friday morning. On Thursday, although there were counter-attractions in the way of excursions and opportunities for automobile trips, a large audience was maintained at both of the sessions. A list of the papers follows, and abstracts will be published in later issues of The Journal:

- A STUDY OF AN AXLE SHAFT FOR A MOTOR TRUCK, John Younger
- A COMPARISON OF THE PROPERTIES OF NICKEL, CARBON AND MANGANESE STEEL BEFORE AND AFTER HEAT TREATMENT, Robert R. Abbott
- THE USE OF CORRUGATED FURNACES FOR VERTICAL FIRE-TUBE BOILERS, F. W. Dean
- ON MEASURING GAS WEIGHTS, Thos. E. Butterfield
- A BASIS FOR RATIONAL DESIGN OF HEAT TRANSFER APPARATUS, E. E. Wilson
- INFLUENCE OF DISK FRICTION ON TURBINE PUMP DESIGN, F. zur Nedden
- THE SURFACE CONDENSER, C. E. Braum
- SOME MECHANICAL FEATURES OF THE HYDRATION OF PORTLAND CEMENT AND THE MAKING OF CONCRETE AS REVEALED BY MICROSCOPIC STUDY, Nathan C. Johnson
- DESIGN OF RECTANGULAR CONCRETE BEAMS, Howard Harding
- MODEL EXPERIMENTS AND THE FORMS OF EMPIRICAL EQUATIONS, Edgar Buckingham

- THE EFFECT OF RELATIVE HUMIDITY ON AN OAK TANNED LEATHER BELT, W. W. Bird and F. W. Roys
- ON THE LAWS OF LUBRICATION OF JOURNAL BEARINGS, M. D. Hersey
- THE RELATION BETWEEN PRODUCTION AND COSTS, H. L. Gantt
- LAWS AND LAPPING, W. A. Knight and A. A. Case

THURSDAY EVENING'S RECEPTION

The reception and dance on Thursday evening was one of the most delightful events which it has been the pleasure of the members to attend at any of the gatherings of the Society. Through the efforts of the local committee the arrangements had been carried to a high degree of perfection. The music was by Moll's orchestra of Rochester, N. Y., which is deservedly one of the popular orchestras of the state, and which contributed much to the pleasure of everyone who joined in the dancing. Late in the evening the party proceeded to the dining room of the Hotel Statler where a collation was served and a social hour was spent.

ENTERTAINMENT FOR GUESTS

The receptions on Tuesday and Thursday evenings have already been referred to in this account as events of much interest. Another pleasurable occasion was the opening of the Twentieth Century Club of Buffalo by its members for the entertainment of ladies and members in attendance at the convention. Tea was served there on Thursday afternoon and a large number accepted the hospitality of the club. Many of the prominent women of Buffalo were in attendance to receive the guests.

During Wednesday and Thursday, automobiles were placed at the disposal of the visitors for trips about the city or for the purpose of reaching manufacturing plants or points of interest. A special trip for the ladies was arranged on Thursday morning to view the interesting points of the city.

Still further, the local committee had thoughtfully made provision for any of the members who so desired to use the facilities of any of the clubs of Buffalo, special stamps being issued for this purpose.

EXCURSIONS

Accounts of the many Buffalo manufacturing plants, which extended invitations to the Society to visit their works during the convention, have already been published in the last two numbers of The Journal. That the members and their friends were appreciative of these invitations is evidenced by the numerous visits which were made. Large parties went to the works of the Lackawanna Steel Company, the Snow Steam Pump Works, the Pierce-Arrow Motor Car Company, Larkin Company, and smaller groups to various other plants. A good many stayed over on Friday afternoon for the purpose of visiting plants which time had not permitted them to inspect on the previous days.

THE ENGINEER AS A CITIZEN

ABSTRACT OF AN ADDRESS BY F. H. NEWELL.

WEDNESDAY EVENING, JUNE 23

In his devotion to technical details does the engineer overlook some of his larger duties as a citizen? This is a question that we may well ask while in the midst of our professional discussions. It has already been ably brought out in the talks of last night by President Brashear and Mr. Baird, that the engineers are "dreamers whose dreams come true." They are men who study to control the forces of nature and who have brought about, especially during the last generation, most wonderful developments along mechanical lines, increasing the strength and efficiency of each worker by a hundred or a thousand fold.

While great results have thus been achieved in the handling of inert material, in the use of iron and steel, in the control of heat and electricity, yet it may well be asked whether there has been corresponding progress on the part of the engineer in the beneficial control of human forces and sentiments? It has been asserted, and quite generally accepted as true, that the typical engineer is a man who sits in his inner office, absorbed in abstruse calculations and wholly unaware of the great changes which are taking place along other lines of growth. It has been further urged that he is not doing his whole share as a man and a citizen, while performing a giant's task in his special line. While each of us must have our specialty, yet the engineers as a whole cannot afford to be so centered upon details as to lose out in broad human interests. If, as has been asserted, the engineer is not receiving such recognition from the public as will enable him to perform the largest public service, is this not due in part to his own neglect of some of these larger matters? This is a question which I wish to raise, not for discussion at this time, but rather for further personal consideration. I will ask each of you to reflect at leisure as to whether you as an individual are doing your full share to let the public know of the achievements of other engineers and of the engineering profession as a whole to aid the public.

It has well been said that the works of the engineer should speak for themselves, but many of the greatest works cannot speak for themselves; they are out of sight, hidden from view, existing as deep and difficult foundations for lofty superstructures, or as tunnels, waterworks and sewers, the essential mechanism for which is buried far from human sight. If the public who pays the bills is to appreciate fully these great achievements, the public must be told of them in language it can understand. The ordinary man cannot and does not read the technical descriptions of these great works. He is interested in them if the larger facts are presented to him in their true perspective and in a way that he can comprehend. He is satiated with startling, sensational stories, and turns with relief to simple, but definite descriptions of engineering works and of the difficulties which have been overcome. It requires, however, something of genius to state clearly and concisely the principal facts of engineering achievements without involving these in a mass of confusing details and technical language. A writer has said, "Any fool can write a book, but it takes a genius to write a paragraph." This applies with equal force to much of our technical literature. Any man of ordinary ability can write

a technical paper which perhaps he and two or three other experts can understand, but it requires a man of somewhat unusual ability to state the same facts in a shorter but interesting manner. There is hardly a technical paper which has been delivered before the Society that does not have the elements of popular interest if the important points are brought out in their true relations to ordinary human affairs.

Assuming that there is some duty along this line which has not been fully performed by the engineers individually or collectively, is it possible for us to rectify these omissions either by definite action by this and other national engineering organizations, or by co-operation among the local engineering societies? My personal belief is that the engineering profession as a whole is capable of being more immediately advanced in public esteem through strong, active, local societies than through any other one agency. These local societies to be effective, however, should be inclusive in the sense that they bring into their membership all engineers of good repute in the vicinity, and associate with them all men who are interested in engineering as a whole, and who are willing to show this interest by attending the meetings or by keeping up the annual dues. The strength of such a local society lies in its ability to diffuse information not only regarding local engineering problems, but also in bringing to the attention of its members and to the citizens of the vicinity the engineering achievements elsewhere, especially those which have a bearing upon the solution of local problems. From my experience in aiding in organizing and in conducting local societies, I cannot too strongly urge the importance of the profession as a whole of the proper stimulation of such organizations. Their best relation to the national societies is yet to be worked out, but it is a problem which undoubtedly will be solved in the near future.

Taking up a little more in detail the duties which may be and should be performed by the engineers acting in co-operation or through local and national societies, attention should be directed first to the necessity of a larger and better education of the public as to the fact, which all engineers recognize, of the superior opportunity and ability of the engineer to answer many of the vexatious questions of civic interest. There has been too general ignorance of the fact, for example, that most of the problems relating to public utilities should be solved on the basis of sound engineering. It should no longer be possible for the Governor of a large state to be unaware of the qualifications of engineers for public utility commissions and with well meaning ignorance pass over the consideration of the appointment of engineers on these commissions. The fact that a Mayor of one of the largest cities of the United States refused to appoint an engineer on a public health board because in his opinion the duties appertained to those of business men and physicians, reflects unfavorably upon the engineering profession of that city in not seeing to it that the Mayor was properly informed on the fact that most of the problems of sanitation are those purely of engineering. In other words, the ignorance of public officials and of the public in general on many of these matters, may be not so much the fault of the individuals and communities as it is of neglect on the part of the engineers as a whole to let it be known that many of these problems lie within the province of the engineer for solution.

Without going further into these details, I will, as before

states, simply raise these points as questions for individual consideration, and take up a brief description of some of the larger pieces of engineering work of importance to all citizens which have been brought nearly to completion by the Reclamation Service of the United States. You as citizens and part owners of the great area of public lands are interested in this work; you are directly or indirectly furnishing the money and should enjoy some of the beneficial results. The work as a whole illustrates some of the "dreams which have come true," and may serve to give a little broader view of the practical applications of mechanical knowledge employed in developing the latest resources of the West. In any event, I should like to introduce you to some of the breezy western optimism and breadth of views which result from life upon the almost boundless arid lands of the west. The views which I am presenting can show only a few of the works for which over \$80,000,000 of public funds have been spent, and which have rendered available for cultivation nearly 2,000,000 acres of fertile land. For this expenditure many large storage dams have been built, holding flood waters and furnishing a supply to many thousand miles of canals and distributing ditches. Connected with this work has been the construction and operation of electrical power plants, mills, steam and electric railroads, commissaries, hospitals, mines, and almost innumerable mechanical devices for the control and distribution of water to furnish opportunities for homes for many thousand families of the type which will form the backbone for a permanent and progressive citizenship, independent and self-supporting—the best and most effective of our people.

MEETING OF THE BOILER CODE COMMITTEE

An important meeting of the Boiler Code Committee was held on Wednesday and Thursday, June 23 and 24, at the headquarters of the Spring Meeting in Buffalo, at which several important actions were taken. Perhaps the most important was that relative to the use of the A.S.M.E. symbol as a boiler stamp. At a previous meeting, the question of authorization of its use in this manner had been referred to the Council, with the result that the Council referred the matter back to the Boiler Code Committee for recommendation and report as to the preferred usage. The result of careful discussion of the subject at this meeting was a resolution offered to the Council, as follows:

It is the opinion of the Committee that the official symbol or stamp is to be used to indicate that The American Society of Mechanical Engineers' rules have been complied with in the construction of the boiler. The stamp shall be affixed by the manufacturer. Certification may be governed by law or contract.

The resolution was accepted by the Council, and it will be of interest to the boiler making industry to know that the A.S.M.E. stamp as prescribed in the Code will be open to general use for this purpose.

Another important problem that had arisen in connection with the Boiler Code was that of interpretation of the rules therein. In a number of cases ques-

tions have arisen since the Code was issued relative to application of particular rules in special cases of boiler construction, and as to the exact meaning of certain of the rules in which the application proves to be obscure. As the result of many requests for interpretation in such cases, a second resolution was offered to the Council by the Boiler Code Committee, as follows:

Your Committee requests that it be empowered to make rulings where inquiries are made respecting constructions not covered by the Code, and to interpret any parts of the Code.

This resolution was also accepted by the Council, and the Committee devoted its entire second session to the consideration of these inquiries and proper replies to them. In all, ten cases were considered and interpretations formulated. It was arranged that each case ruled upon shall be given an index number, and the ruling thus made shall stand as a permanent interpretation of the particular portion of the Code involved.

Further arrangements for the interpretation work were made at this meeting in order that no obstacle be placed in the way of the application of the Code to the industry, by a provision for quarterly meetings of the Committee, or as much oftener as may be necessary, for consideration of such inquiries for rulings. The importance of this phase of the Committee's work was fully recognized, and it is hoped that by this plan the application of the Code to conditions in any community may be facilitated and its usefulness extended.

Recognition was given to the International Engineering Works, Framingham, Mass., for the copy of official tests on boiler joints which had been made at the Watertown arsenal for this Company on May 15, 1915. The receipt of this report of test data was acknowledged, and a resolution was offered that it be placed on file in the United Engineering Library in New York City.

Consideration was given to the matter of the index that has been prepared for the Boiler Code, and it has been ordered printed with slight revisions and a change of arrangement. The index will be arranged in two parts, one a complete alphabetical index of the entire work, and the other a divisional index divided into three parts, one corresponding to each of the three principal parts of the Code. It is intended that this index shall be incorporated in the next edition of the Code, which will, in all probability, be printed early in the Fall.

The matter of further work of the Boiler Code Committee was considered at this meeting, and the result was a third resolution offered to the Council as follows:

Your Committee requests that it be empowered to take up the subject of (1) economizers; (2) pressure vessels; (3) rules for operation and care of steam boilers and pressure vessels; and (4) recommendations.

This request was also granted by the Council, and the Committee thereby authorized to proceed with this work as originally intended.

CONFERENCE OF LOCAL SECTION REPRESENTATIVES

The conference of local sections at the Spring Meeting reflected the wisdom of the Council in appointing the Committee on Local Sections last January. The personnel of this committee is: Elliott H. Whitlock, chairman, W. F. M. Goss, Louis C. Marburg, Walter Rautenstrauch, and D. Robert Yarnall; two of the committee are members of the Council, one the president of the Cleveland Engineering Society, and another past-president of the Philadelphia Engineers' Club, and they are, therefore, well-qualified to develop this important phase of the Society's activities.

There were present delegates from all parts of the country representing the following centers where sections are established.

Atlanta, FRANK H. NEELY

Buffalo, DAVID BELL, C. H. BIERBAUM, W. H. CARRIER, and JOHN YOUNGER

Chicago, P. A. POPPENHUSEN

Milwaukee, LOUIS E. STROTHMAN

Minnesota, MAX TOLTZ

New Haven, GEORGE S. BARNUM

New York, H. R. COBLEIGH

Philadelphia, D. R. YARNALL

St. Louis, E. R. FISH

San Francisco, C. F. BRAUN

Worcester, E. HOWARD REED and JAMES A. WHITE

The first session of the meeting, which continued through three sessions, took the form of a dinner on Tuesday evening with after-dinner speaking confined to the subject of Local Sections. The great interest which was manifested in the conference is evidenced by the fact that at the various sessions there were present, in addition to the regular delegates, Dr. John A. Brashear, President of the Society, James Hartness, Past-President, John R. Freeman, Past-President, H. G. Reist, Vice-President, Henry Hess, Vice-President, A. M. Greene, Jr., Manager, Calvin W. Rice, Secretary, and H. Wade Hibbard. In attendance also were William P. Caine, representing Birmingham, Ala., William T. Magruder, representing Columbus, Ohio, and H. H. Esselstyn representing Detroit, Mich., which centers now have the establishment of local sections under advisement, and Luther D. Burlingame representing Providence, R. I. The only sections which were not represented at the meeting were Boston, Cincinnati and Los Angeles.

The Committee on Local Sections had collected data from which the chairman had plotted curves showing the number of meetings held during the past year by the various sections, the cost per meeting, the attendance per meeting and the cost per member per meeting. These figures brought out many discrepancies and showed that the average cost of each meeting varied from \$30.00 at San Francisco to \$114 at New York. Other curves showed that the cost of meetings per

member per year varied from 50 cents per member to over \$2.50 per member.

Each representative present was given opportunity to put on record the ideas of his section and this information should prove of great assistance to the Committee on Local Sections in formulating plans which will, as nearly as possible, unify the procedure of all sections and also establish a basis for appropriating funds for carrying on their activities, which it will be endeavored to have commensurate to the requirements of the different sections and on as liberal a basis as the various activities in which the Society is engaged will permit.

Wide differences of opinion were expressed as to the relations which should exist between the Society and the sections and as to the scope of their activities. The delegates returned to their various sections with many new ideas which should prove a boon to the work, and the investigations of the committee will be continued through correspondence so that a satisfactory solution of the question will be found as promptly as possible.

INCREASE OF MEMBERSHIP

At the Spring Meeting the Chairmen of Sub-Committees on Increase of Membership met for the purpose of exchanging ideas, and planning ways and means of securing for the Society the support of the many leading engineers in various parts of the country who have not yet become affiliated with the Society.

The Chairman of the Committee, I. E. Moulthrop, found it impossible to be present, but sent a letter addressed to those in attendance of which the following is an extract:

"I have one thought to suggest to our Committee. In almost every instance where a member of the Society has not enthusiastically responded to our request for help, he has emphasized his thoughts that people are prone to weigh the tangible returns they would receive from membership in our Society against the annual expense of that membership. This is a very practical viewpoint, but frankly, is a very short sighted and selfish one. If I were so situated that I received absolutely no tangible return for my membership in the Society, I should still feel that it was my duty to continue as a member; I should feel that I ought to do something for the mechanical engineer, something for the general good of the profession that furnishes a living to the mechanical engineers of this country. In the address given by L. B. Stillwell at the third Mid-Winter Convention of the Institute of Electrical Engineers, New York, February 17, 1915, he says in one place:

'The opinion is widely prevalent throughout the ranks of the profession that the true status of the engineer is not recognized by those about him; that the work which he has done and is doing in the world entitles him to a larger place in the public view than he now occupies and to a larger share in the administrative work of the nation, state, local community, and of our great railway and industrial corporations than he now enjoys.'

"Mr. Stillwell's statements, in my opinion, are absolutely true and the responsibility for the situation is with the mechanical engineers of this country. They do not take themselves seriously enough, and they are not a unit in trying to impress the world that the mechanical engineering profession is in importance second to none. English people are very frank in stating that the present European war is a war of engineers, and if this is so, mechanical engineering must play the principal role.

"I am not only willing but glad to make my small contribution towards the general benefit of the engineering profession, and I think every other engineer ought to feel he has a similar duty. I think we should make more of an effort to impress this viewpoint on the large number of engineers who are not but should be members of our Society."

The following were present at the two sessions of the Committee: F. H. Neely of Atlanta, W. H. Carrier of Buffalo, P. A. Poppenhusen of Chicago, H. H. Esselstyn, N. G. Reinicker and A. L. Burgan of the Michigan Committee, Max Toltz of St. Paul, J. A. Kinkad of New York, E. R. Fish of St. Louis, and C. F. Bamm of San Francisco.

The members of the Committee were urged to impress those members of the Society with whom they come in contact that in no instance is an invitation to join ever extended by the Society or any of its officers as such. The work of the Committee on Increase of Membership is confined to urging the membership at large to see to it that every engineer of attainment is affiliated with the Society and giving through it his moral support to promoting the best interests of his profession.

Those associated in the work of the Committee on Increase of Membership and its Sub-Committees should always act as individuals when extending to their friends and associates an invitation to apply for membership.

Emphasis should also be made of the fact that the membership has greater opportunity now than ever before to make objection to candidates who should not be admitted. The method formerly used provided every voting member with a pamphlet containing a summary of the professional qualifications of those who had applied for membership during the previous six months.

The last issue of this pamphlet contained 208 pages of data covering 619 applicants. Inquiry proved that the great expense in publishing and distributing this information was not warranted because of the small percentage of the membership who took the time and trouble to peruse it.

In its stead was adopted a more simple but just as adequate system and at but a fraction of the cost. This consists of publishing the name, occupation, and address of the applicant listed under a heading for which his age and professional qualifications appear to fit him.

This method makes it possible for every member to examine the list every month. If any member, voting or otherwise, questions the eligibility of anyone posted, he may receive upon request a complete copy of the professional record of that applicant. Any applications for which information is requested, are held up until careful investigation is made and the member raising the question has had opportunity to give complete details, and these are either disproved or the application is indefinitely deferred. This gives the member an opportunity to secure information concerning those whom he questions without the trouble of looking through a lot of details regarding applicants he does not know.

The Membership Committee, made up of an entirely separate group of members than those working on the Increase of Membership Committees, uses the utmost care and gives most careful scrutiny to the records of the applicants, the remarks made by sponsors and any information which may be sent in by other members of the Society.

That the efforts of the Committee on Increase of Membership have borne fruit is evidenced by the following table:

RECORD OF APPLICATIONS RECEIVED MONTHLY FOR THE PAST EIGHT YEARS

(Committee on Increase of Membership Appointed in January 1912)

	1908	1909	1910	1911	1912	1913	1914	1915
January.....	28	29	35	44	44	140	92	49
February.....	21	39	40	54	81	240	110	123

Owing to the general condition of business the activities of the Committee on Increase of Membership were reduced to the minimum last summer, and the result is apparent in the figures from August 1914 to January 1915. It will be noted that in the first six months of 1914 a total of 729 applications were received, whereas in the corresponding period this year 629 applications have been filed.

Many of the most prominent engineers now in the Society have joined since 1911, and in almost every instance their affiliation was the result of activity on the part of some member connected with the Committee on Increase of Membership. The high standard of the membership acquired during the past four years is shown by a perusal of the Year Book and a comparison of the members shown to have entered the Society since 1911 with those who entered prior to that time.

COUNCIL NOTES

A meeting of the Council was held in Buffalo, Thursday, June 24, 1915, at Society Headquarters, Hotel Statler.

The President announced the appointment of a committee consisting of Charles Whiting Baker and A. M. Greene, Jr., to represent this Society in conferences to be called by the American Society of Testing Materials.

Mr. Whitlock, chairman of the Committee on Sections reported that there was a great deal of interest shown in the conference of the representatives of the sections, which was then in progress. These representatives had come from all portions of the United States, including even San Francisco and Atlanta.

The Secretary reported the deaths of B. F. Isherwood, Honorary Member, John Birkinbine, G. T. Reiss, A. L. Bowman, John P. Zipf, and James T. Halsey.

Honorary Vice-Presidents which included H. R. Towne, W. M. McFarland, J. B. F. Herreshoff, Stevenson Taylor, had been appointed to represent the Society at the services to Mr. Isherwood; at the memorial services in honor of F. S. Pearson, J. W. Lieb, F. A. Halsey, H. G. Stott, F. A. Goetze were appointed as Honorary Vice-Presidents.

Election of applicants for membership was announced, on the ballots which closed May 29, and June 19th.

The resignation of C. W. Huntington was accepted.

Nominations for officers for the ensuing year were reported by the Nominating Committee, and appear elsewhere in the Journal.

The Council confirmed the appropriations of \$100 approved by the Executive Committee for the work of the Committees on Student and Junior Prizes.

Approval was given to the appointment of E. A. Stillman on the Committee on Hydraulic Flanges.

Prof. Arthur M. Greene, Jr., one of the representatives of the Society on the joint Engineers' Committee with reference to the constitutional convention, reported the progress that had been made in recommending changes in the constitution, with respect to engineering matters.

The Committee on Sections in San Francisco, consisting of F. W. Gay, Chairman, F. H. Varney, Vice-Chairman, C. F. Braun, Secretary, H. L. Terwilliger, J. T. Whittlesey, likewise the Chicago Section Committee was approved, of H. M. Montgomery, Chairman, Joseph Harrington, Vice-Chairman, Robert E. Thayer, Secretary, Charles E. Wilson and H. T. Bentley.

New Orleans was chosen as the place of the Spring Meeting, 1916. The Society has never met in New Orleans, and has been in receipt of very cordial invitations for several years past, from the members there and from the Louisiana Engineering Society.

REPORT OF THE NOMINATING COMMITTEE

The Secretary announces the receipt of a report from the Nominating Committee in which the following names are offered as candidates for the offices indicated:

For President:

D. S. JACOBUS, New York

For Vice-Presidents:

WM. B. JACKSON, Chicago, Ill.

J. SELLERS BANCROFT, Philadelphia, Pa.

JULIAN KENNEDY, Pittsburgh, Pa.

For Managers:

JOHN H. BARR, New York

JOHN A. STEVENS, Lowell, Mass.

H. de B. PARSONS, New York

For Treasurer:

WM. H. WILEY

COMMITTEE ON PROTECTION OF
INDUSTRIAL WORKERS

The Committee on Meetings has recently established a Sub-committee on Protection of Industrial Workers. The members of this new committee are: JOHN H. BARR, *Chairman*; MELVILLE W. MIX; JOHN PRICE JACKSON; WILLIAM A. VIALI; JOHN W. CUP.

This committee desires to avoid all unnecessary duplication of work or conflict with the activities of other organizations, but is anxious to perform its part in bringing about the standardization of effective and practical protective devices and methods.

In order to define properly its scope and determine its limits of activity it solicits information as to what has been done and is being done through other agencies. These agencies include state bureaus, insurance interests, organized societies or their committees, departments of industrial concerns and individuals. Suggestions as to sources of such information, especially reports of committees and codes for safeguarding industrial risks, are solicited. The new committee of the A.S.M.E. asks the assistance of those already engaged in the safety movement, and desires to reciprocate by cooperating with others interested in establishing a more systematic practice in the reduction of industrial accidents.

It is the intention of the committee not to hastily recommend standards; any action in that direction will only follow mature consideration of all the pertinent evidence available. An effort will be made to review the work of other agencies and to secure the advice and opinions of those who can speak with authority before attempting any specific recommendations.

The field which may be covered is a large one and the committee will probably find it desirable to restrict itself to the consideration of certain classes of risks at the beginning of its work, extending to other lines later, as conditions and development may warrant.

The first work will be a survey and digest of what has been done, having particular regard to legal codes which have been adopted in various States, regulations and requirements of insurance organizations, and codes which have been adopted by other associations.

It is obvious that such safeguards as should be applied to machinery can best be supplied with the machines by the maker. This procedure will result in guards better in design and lower in cost than if made by hand in the works of the purchaser. No doubt the purchaser would give preference, other things being at all equal, to machines provided by the maker with well designed protective features. The manufacturer will appreciate the value of such features as selling points, especially after these get some vogue.

The great obstacle to the adoption of this practice of "built in" safeguards is the diversity of requirements and conflicting regulations in force in different

Mengel; George W. Dickie, Vice-President, Am. Soc. M. E.; Lient, G. W. Danforth, Chief of the Dept. of Machinery; W. H. Onken, Jr.; Prof. C. M. Jansky; Geo. M. Brill, Mem. and Past Vice-President, Am. Soc. M. E.; Emil Fischer and Calvin W. Rice, Secretary of the Am. Soc. M. E. Those standing are, from left to right: Captain B. C. Bryan, U. S. N.; Fred R. Low, Mem. Am. Soc. M. E.; John Hunter, Manager Am. Soc. M. E.; Captain C. A. McAllister; F. J. Frank; D. S. Watkins; W. H. Crosby; Cecil P. Poole, Mem. Am. Soc. M. E.; Carl Hering; H. W. Bringhurst; Thomas Norriss; Prof. Wm. H. Kavanaugh, Mem. Am. Soc. M. E.; Jesse M. Smith, Mem. and Past-President, Am. Soc. M. E., and N. A. Bowers.

The exhibits in the machinery buildings and those in the exposition generally which had to do with mechanical and electrical devices were divided nearly equally among four group juries. These juries were

MEMBERS OF THE FOUR GROUP JURIES OF PANAMA-PACIFIC INTERNATIONAL EXPOSITION

sections of the territory over which any given product is distributed.

If The American Society of Mechanical Engineers, cooperating with other agencies, can effect an approach to uniform requirements in this matter, it will materially contribute to the reduction of accidents, and will vastly reduce the annoyances incidental to complying with legal and insurance requirements.

To expedite an approach to this desirable estate is the first aim of the Committee on Protection of Industrial Workers.

INTERNATIONAL JURY OF AWARDS

PANAMA-PACIFIC INTERNATIONAL EXPOSITION

On this page is published a photograph of the four group Juries of Awards of the Panama-Pacific International Exposition having to do with machinery exhibits. The names of the gentlemen seated, reading from left to right, are: Prof. H. Wade Hibbard, Mem. Am. Soc. M. E.; Prof. Charles E. Lucke, Mem. Am. Soc. M. E.; Prof. John T. Faig, Mem. Am. Soc. M. E.; J. C.

smaller than in previous expositions for the reason that it has been found that a small group is more efficient than a large one.

The chairmen of the respective groups were: Mr. Dickie, Tools for Shaping Wood and Metals; Mr. Brill, General Machinery and Accessories; Mr. Low, Steam, Gas, Hydraulic and Other Motors; and Mr. Onken, Electrical Machinery. These gentlemen, together with the Chief of Exhibits, Mr. Danforth, became members of the Grand Jury which is still in session.

There were over 600 separate exhibits, about 150 to each group jury, and, in turn, each of the exhibits contained one or more items for which the exhibitor wished separate consideration.

The work of the juries consisted in passing upon each individual item, assigning a mark on a scale of 100, to a definite schedule representing the features which one should take into account in judging the exhibit, such as its usefulness, attractiveness, instructiveness, length of time the firm making it had been in business, whether or not the firm had received previous

awards for the same lines of manufacture, etc. The sum of the individual marks which each member of the group jury secured was reported to the secretary of his group and the average taken. This indicated whether there should be given no award, honorable mention, bronze medal, silver medal, gold medal or medal of honor, and the vote was taken by the entire group confirming the award.

The care and unanimity of judgment of the individual members of the jury was indicated by the fact that the scheme of marking was so well thought out, and methods of arriving at judgments so definite, that the percentage variation from the average was usually very slight. Any person's individual judgment after the awards had been made by the group jury was in turn recommended to the superior jury for its review.

ENDORSEMENT OF THE BOILER CODE

Full endorsement of the Boiler Code as a set of rules for stationary boiler construction was the result of a resolution adopted by the Master Boiler Makers' Association at its ninth annual convention held recently at Chicago. The Executive Committee of the Association, after investigation, made the recommendation that the Association should adopt the A. S. M. E. Boiler Code, and this recommendation was favorably voted upon by the Association. The opinion was expressed that the Boiler Code is the best set of boiler rules that has ever been published and it was hoped that it would become a standard throughout the entire country.

Also advices have just been received that the A.S.M.E. Boiler Code has been adopted by the Industrial Board of the State of Pennsylvania and by the Board of Boiler Rules of the City of Detroit as their standards of boiler construction in their respective districts. It has also been reported that the use of the A.S.M.E. Boiler Code is being strongly agitated in the State of California, as well as in a number of other States, and it is said to be more than likely that it will be the standard of boiler construction in a large proportion of the States of the Union before the end of the year.

WORCESTER POLYTECHNIC INSTITUTE

The fiftieth anniversary of the founding of the Worcester Polytechnic Institute was celebrated on June 9. Delegates from nearly ninety colleges, universities and technical schools and from eight engi-

neering societies were present. The Society was represented by Dr. John A. Brashear, President, and Calvin W. Rice, Secretary. Among the speakers were David I. Walsh, Governor of Massachusetts; A. Lawrence Lowell, LL.D., president of Harvard

WORCESTER POLYTECHNIC INSTITUTE

University, and George I. Alden, of the board of trustees of the Institute and member Am. Soc. M. E.

Ira N. Hollis, president of the Institute, in his introductory address, expressed his regret that important duties elsewhere prevented President Wilson and Major-General Goethals from attending the function. He traced the connection between the hard experience of the men who had, on both sides, gone through the four years of the Civil War, and the subsequent rapid growth of the American industries led, to a large extent, by the men who, in the words of the speaker, have "brought away from four years of hard fighting, clean hearts." The problem of the day in this country is the necessity of greater care of our natural resources and less waste of available material. Recent laws have not accomplished as much by direct enforcement as they have by indirection, by public discussion, or by the formation of public opinion. In this aspect of American life the universities and colleges have a more important function than the legislatures.

President Lowell compared the life led by the Romans with that of the present generation. The conditions of life were profoundly different from what they are today, and in many cases the gulf in moral conceptions was nearly as deep: in Athens, Plato and Socrates said that slavery was an absolute necessity, not only for human prosperity but still more for human progress. It was not so much the change in morals, as the progress in engineering, control of the forces of nature, that brought about the establishment of the new, and better order of things, but, President Lowell added with emphasis, in controlling the forces of nature, one should know something of the com-

munity in which one lives, and the effects which a certain application of these forces will produce on the life of the community.

The same strain, the imperious need of a connection between the work of the engineer as such as a member of the community of which he is a part, was still more forcibly impressed in the address of Governor Walsh of Massachusetts. An institution like the Worcester Polytechnic Institute, he said, is specially valuable to the commonwealth in that it equips men to grapple with the problems of government, and to "preserve the blessings and the liberties the people enjoy unsullied and unstained," a significant statement when addressed to a purely technical institution.

The address of George I. Alden was given before a meeting of the local section of The American Society of Mechanical Engineers, held in the afternoon and simultaneous with the celebration exercises. His address appears elsewhere in this issue.

CONVENTION OF THE NATIONAL ASSOCIATION OF CORPORATION SCHOOLS

Of general interest in connection with the meeting on June 8 of the Worcester local section of the Society, and of the celebration of the fiftieth anniversary of the foundation of Worcester Polytechnic Institute, referred to elsewhere in this issue, is the third annual convention of the National Association of Corporation Schools that was held at Worcester at that time. The meetings which extended over four days, June 8-11, were presided over by Charles P. Steinmetz, president of the Association, Mem. Am. Soc. M.E., and they were devoted to discussions of the many important problems entering into industrial education, such as trade apprenticeship, special apprenticeship schools, vocational guidance, office work schools, etc. More than 150 representatives of many of the largest industrial corporations in the country were present.

The address of welcome was made by George I. Alden, president of the Norton Companies, who gave the reasons why such large corporations may conduct schools in their own works and at their own expense. He pointed out the great opportunity offered by the Association for corporations to come into closer relations of personal contact, knowledge, and interest with their employees, to offer them vocational guidance, to increase the wages of employees by increasing their specific knowledge, and consequently their value to the corporation, and thus secure a unity, permanence, and efficiency throughout the whole organization, which will be of mutual benefit to all.

In connection with the meetings of the Association which were held in Higgins Hall of the Worcester Boys' Trade School, the memory of Milton P. Higgins, who was a member of the Society, was honored as founder of the school. Mr. Higgins, who was referred to as the father of trade schools, believed that the productive shop was an essential factor in successful trade

training, and his early work in connection with the Polytechnic Institute and later—in founding the Trade School, which was the culmination of his twenty-eight years of business life at the Polytechnic Institute, proved that his belief was well founded. His memory was honored by the presentation of two fine bronze tablets which have been placed by his family at either side of the entrance of the Trade School for Boys building.

JOHNS HOPKINS UNIVERSITY

On May 20, Dr. Frank J. Goodnow was installed as the third president of Johns Hopkins University at Baltimore, Md. The inauguration was preceded by a procession of the delegates consisting of presidents of more than fifty American and Canadian colleges and universities, faculties, trustees, alumni and graduate and medical students. The Society was represented by Prof. Carl C. Thomas, professor of mechanical engineering at the University. Dr. Goodnow in accepting the responsibilities of the office, made an address on Modern Educational Ideals. He said in part:

The complaint is often made that modern education is too practical in its aims, and as a consequence, the coming generation will lose much of the beauty and richness of life which those of the present owe to their pursuit in past years of what are usually called cultural as opposed to vocational studies. An examination of the history of universities would seem to show that almost everywhere and at almost every period the primary purpose of those seeking an education has been in very large measure a distinctly practical one. This purpose has been to acquire proficiency in the profession which they intended to follow. Even in the earliest time, tendencies were toward the practical side, and gradually subjects crept into the universities which were once considered in the nature of trades, but which were later looked upon as learned professions. The first of the new professions to be recognized by the university was medicine. Just as the development of an approximately scientific medicine resulted in transforming medicine from a trade into a learned profession, so the development of the engineering sciences has made the engineer out of the artisan, the architect out of the builder, and the scientific chemist out of the alchemist. At the present time, furthermore, new sciences and professions are in the making, such as the scientific agriculturist, the scientific forester, the naval architect, and the efficiency engineer.

It may be truthfully said, however, that educational ideals while perhaps more practical than formerly, are really to be distinguished from former ideals by reason of the fact that they are broader and more comprehensive. We no longer consider education as purely vocational or purely cultural. We no longer confine our study to theology and philosophy or to literature and mathematics. The functions of modern education are manifold.

They include the disciplinary training of the young along general lines, the transmission of that particular knowledge of the past which will do most to develop persons of culture, the applications of scientific methods to the conduct of the

PANORAMIC VIEW OF THE

ordinary affairs of life, the increase of our knowledge through research and investigation and the rendering of public service. None of those ideals is to be despised as unworthy of pursuit by men of learning. None perhaps may be selected as more worthy of pursuit than the rest.

On the following day, Dr. Henry C. Adams, professor of history of the University of Michigan and the first graduate of Johns Hopkins University, gave an address at the dedication of Gilman Hall. It sounded very forcibly the call to the study of those things contributing to the larger life of mankind without reference to the utilitarian objects of study, and was a plea for the things of the spirit.

Following Dr. Adams, and as the final feature of the program, General Goethals made a splendid address at the dedication of the Engineering buildings. After having pointed out the wonderful development of the creative arts in the last century, the speaker defined the relation between material progress and the moral progress of mankind. He said further:

In man much of the brute still remains, but, although no marked progress can be observed in the subjugation or eradication of human passions, the engineer has shown advancement in his cult, the direction of the great sources of power in nature to the use and convenience of man. The present war may be expected to be followed by an era of great industrial advance. Notwithstanding its horrors, war assists progress, as new industries are developed, and inventive genius is aroused and stimulated.

The work of the engineer is gradually tending to bring him into closer contact with other spheres of activity: with the physician in the preservation of public health; the lawyer in the drafting of contracts, enforcing and perhaps contesting them; perhaps even with the clergy in the handling of motley crowds in construction camps.

In the United States, it was the army that supplied the first engineers. West Point was the first, and for some time the only technical school in the country, and its graduates ranked high among the engineers of the United States. Later, when technical education was undertaken by the colleges and universities, graduates of the Military Academy were found among instructors and professors. Furthermore, it was the army which started the great work which subse-

quently developed into what is now known as the U. S. Geological Survey and the Coast and Geodetic Survey.

The speaker proceeded then to give a brief but highly interesting account of the creation of the department of engineering at the Johns Hopkins University, and made an eloquent defense of the principles laid at the foundation of its program. After all, in the words of Maj. Gen. Goethals, it is not the amount of technical information that is of importance. What is needed is so to train the mind that it can grapple with reasonable hope of successful issue the various problems that will arise in after life; and this is accomplished best by a thorough grounding in and mastery of the theory of the fundamentals.

THE GETTING-TOGETHER OF THE ENGINEERING PROFESSION AT SAN FRANCISCO

Traveling by the Engineers' Special to the International Engineering Congress at San Francisco will afford a unique opportunity for engineers and their friends to meet, on one train, the officers and members of the five national engineering societies under whose auspices the Congress is being held.

For a number of years, there has been developing a spirit of cooperation among the national engineering societies, and it is believed that the Congress will serve to unite further not only the engineering societies of America but also those of the entire world in one common effort.

The details of the excursion to San Francisco are briefly as follows:

Round trip ticket, via the Engineers' Special and returning by any route, can be purchased for \$28.50 Pullman service and meals are of course extra.

The train leaves New York City at 7:45 p. m. on Thursday, September 9, and arrives in San Francisco at 9 o'clock on the evening of Wednesday, September 15.

The outgoing trip will allow stop-overs at Niagara Falls, Colorado Springs and the Grand Canyon.

Each of the national engineering societies will hold separate professional meetings on Thursday, Septem-

PANAMA-PACIFIC INTERNATIONAL EXPOSITION

ber 16 and Friday, September 17. On Saturday and Sunday, September 18 and 19, excursions to points of engineering interest will be organized. These excursions include visits to the Portrero Gas Works, the largest gas station on the Pacific Coast, the San Francisco High Pressure Fire System, the Great Western Power Company's Hydroelectric Development, the Spaulding-Drum Development of the Pacific Gas and Electric Company and the Coalina Oil Fields. During the following week, beginning September 20, the sessions of the Congress will be held jointly.

Col. G. W. Goethals will act as Honorary President of the Congress and is expected to preside in person over its general sessions. Prof. W. F. Durand is chairman and W. A. Cattell, secretary.

The papers presented will cover the general field of engineering and are intended to treat the various topics in a broad and comprehensive manner, with special reference to the important lines of progress during the past decade, the present most approved practices and the lines of present and future development. Furthermore, each will be accompanied by a bibliography of his subject.

The Congress has been handled with special wisdom on the part of a very loyal committee of which Prof. W. F. Durand is chairman, and by A. M. Hunt, chairman of the meetings committee. These men have given several years of unselfish devotion to the work, without remuneration of any kind. Notwithstanding this, the cost of literature, maintenance of headquarters, printing and publication of papers will be considerable and the Engineering Societies have undertaken to underwrite these expenses, but it is earnestly hoped that the members at large will support the Congress by their cooperation. The fee for membership in the Congress is only five dollars, but if a sufficient number of members enroll, the entire expense will be paid without calling upon the parent societies.

The Congress is a celebration by the United States of the greatest engineering achievement ever under-

taken in the history of the world. It is fitting, therefore, that every engineer should be officially represented in its membership.

The following is a partial list of those who have signified their intention of attending the Congress and of journeying by the Engineers' Special. In this partial list only members of this Society are included. A total of 145 are now scheduled for the official train, from New York and 21 for the train from New Orleans.

Nicholas S. Hill
Edwin B. Katto
Bradley Stoughton
Leonard McVitt
Wm. H. Wiley and Mrs. Wiley
John H. Bernhard and Mrs. M. B. Bernhard-Nagle
G. R. Tuska and Mrs. Tuska
W. L. Saunders
L. K. Comstock and party
James Hartness and Mrs. Hartness
R. J. Hill and Mrs. Hill
G. W. Fuller and Mrs. Fuller
Calvin W. Rice
Alex. C. Humphreys, Mrs. Humphreys and party
Ira H. Woodson and Mrs. Woodson
Charles A. Mead
A. Stucki, Mrs. Stucki and party
Frederick L. Schmidt and Mrs. Schmidt
A. H. Goldingham and Mrs. Goldingham
R. M. Clayton and party
Paul C. Philipp
Laurence C. Bowes
Red Jones
Paul H. Grimm
W. J. A. Louchan
H. A. Freyn and Mrs. Freyn
R. V. Norris
Robert B. Wolf and party
James M. Dodge, Mrs. Dodge and party
W. R. Warner, Mrs. Warner and party
Carl F. Dietz and Mrs. Dietz
P. M. Lincoln, Mrs. Lincoln and party
Henry G. Rest and Mrs. Rest
Robert W. Hunt
Frank R. Gilbreth and Mrs. Gilbreth

The headquarters of the Society will be at the Hotel Chitt. The local arrangements will be in charge of a Committee on Local Affairs. A general program of the Congress and of the excursions will be mailed to members of the Society on request.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON AUGUST 10, 1915

MEMBERS are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their age would qualify them and not with regard to professional qualifications, i.e., the age of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of grading are also posted.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

- ADAMS, JAMES F., Supt. and Vice-Pres., The Canister Co., Phillipsburg, N. J.
- ALQUIST, KARL, Engr., General Elec. Co., Schenectady, N. Y.
- APPLER, A. BENJAMIN, Mech. Engr., The Delaware & Hudson Co., Watervliet, N. Y.
- AUTEN, JAMES E., Asst. Supt. Bldgs. and Equipment, Cadillac Motor Car Co., Detroit, Mich.
- BAREUTHER, ADOLPH A., Insp'lr., The Panama Canal, Washington, D. C.
- BERTHOLD, FRANK C., Mech. Foreman, Illinois Steel Co., Gary, Ind.
- BOSCH, FREDERICK W., Designing and Cons. Engr., Murray Iron Works, Burlington, Ia.
- BOYNTON, JOHN E., Ch. Engr., American Brick Co., Lincoln, Ill.
- BROOKS, PERCY C., Vice-Pres., Canadian Fairbanks Morse Co., Ltd., Toronto, Ont., Can.

ICE-MAKING AS A BY-PRODUCT OF CENTRAL STATIONS

BY HEYWOOD COCHRAN,¹ CHICAGO, ILL.

Non-Member

ALTHOUGH ice plants have been operated in connection with electric light plants for a considerable time, it is only within the past five years that the possibilities for profit in such a combination are beginning to be appreciated. These ice plants may be conducted in either of two ways: *First*, as the property of the central station, in which case they are usually located adjacent to the power plant; *Second*, privately owned, purchasing current or steam from the central station. The latter are usually motor driven compression plants, located at the point best adapted for the distribution of ice.

FIG. 1. DIAGRAMMATIC VIEW OF A SECTION OF A MODERN ICE TANK OF THE FLOODED TYPE

One point of difference between electric light and ice plants is the limit of size for economical distribution. For the former this is indefinite, but the latter soon reach a size where the cost of distribution more than offsets the saving from a central plant. There are in operation plants of 300 to 500 tons capacity, but individual plants of from 80 to 150 tons capacity are preferable. Except for the cost of distribution, however, a plant owned by a central station if properly designed can make ice cheaper than any ice plant in the second class or any other privately owned plant.

In order to explain why certain kinds of ice machines are better adapted for the first class and others for the second, a brief description of the methods of ice manufacture will be given. While there are a number of different refrigerants, only ammonia will be considered, as it can be used in both compression and absorption ice machines. Ammonia, as is well known, is a gas at atmospheric pressure and all ordinary temperatures, but it may be liquefied by compression, the

pressure required depending upon the amount of condensing surface, type of condenser and temperature and amount of condensing water available. The liquid, usually known as "liquid anhydrous" (although it is not always anhydrous), must then absorb heat before it can again become a gas.

Fig. 1 shows a section of a modern ice tank of the "flooded" type. The liquid anhydrous passes from the ammonia condensers into the receiver on the left and then enters the coils in the tank at the bottom, through a valve known as the "expansion valve." The ice cans are filled with water and the surrounding space with brine. The liquid anhydrous

in the coils absorbs heat from the brine, which in turn absorbs heat from the water in the cans, taking up 142 B. t. u. from every pound of water at 32 deg. in order to form ice at the same temperature. The resultant gas is removed from the coils to be recondensed and it is in this process alone that the absorption and compression systems differ.

While in the compression system the ammonia gas is mechanically sucked out of the coils by a compressor, in the absorption system, it is sucked out by its strong attraction for water, making aqua ammonia. An absorption machine involves the use of heat exchanging apparatus comprising absorber, generator, etc., as indicated in Fig. 2, which shows a typical absorption machine of the double pipe and tubular type. Here the expanded gas is to be removed from brine cooler coils. The absorber, which is the heart of the system, is built like a horizontal tubular boiler, with 2 in. tubes through which cooling water passes. Weak aqua, which has had a part of its gas driven off, enters the top. On the suction stroke of the machine the gas bubbles up through this weak aqua, changing it into strong aqua, which is pumped into the ammonia boiler or generator, where steam passing through coils drives off the gas and produces sufficient pres-

¹ Western Manager, Carbondale Machine Co.

sure to condense it. The rectifier is a drier and the exchanger is the feed water heater of the system. The aqua pump, which is the only moving part, requires about $\frac{1}{30}$ h.p. per ton of ice and can be driven either by steam or motor. The action of the generator in this case takes the place of the compression stroke. Instead of having only one cycle as in the compression system, there are two, the strong and weak aqua cycle being the second.

Thus the compression machine requires power only while the absorption machine requires practically heat only, and a highly economical ice plant can be made by a combination of the two systems, especially if raw water ice is made as in the case of the electrically driven compression plant. With cold condensing water, say under 70 deg., it is possible

larger cities, such as Chicago, the privately owned, electrically-driven ice plant is the proper combination, while in the smaller cities, he will find it much more profitable to own the ice plant direct. Whether it is more profitable in the larger cities from the ice plant manager's standpoint to purchase current at a power cost of 50 cents per ton or over is very questionable and will depend largely upon circumstances. Some figures from an independent exhaust-steam ice plant will be of interest.

Table 1 gives the coal cost per ton on ice made in such a plant with coal at \$1.80 per ton. The coal used was of various kinds, although that at \$1.80 per ton was Indiana No. 4. All ice was made from distilled water. The coal cost per ton is only 20 cents. Adding the fireman's wages and interest and

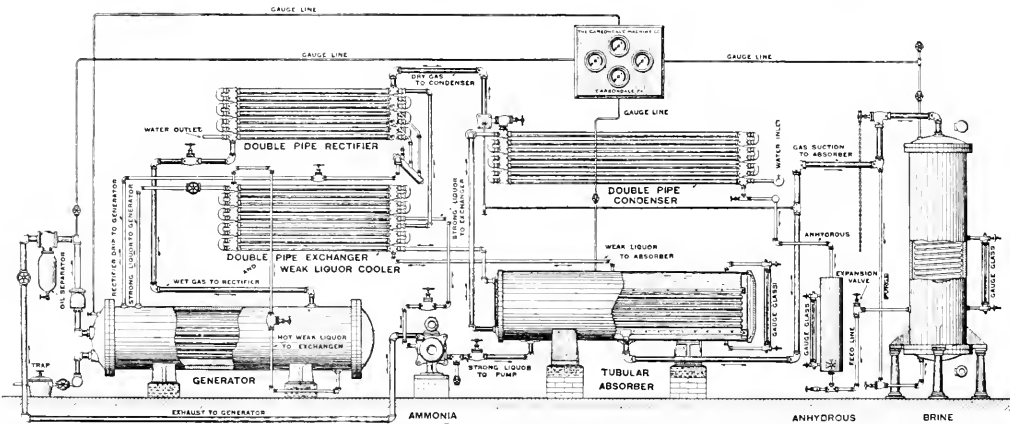

FIG. 2 DIAGRAM SHOWING GENERAL ARRANGEMENT OF A TYPICAL ABSORPTION REFRIGERATING MACHINE OF THE TUBULAR TYPE

to use exhaust steam at 3 lb. pressure in the generator. This steam is condensed, furnishing a portion of the distilled water required for making ice. About 55 to 60 lb. of steam per hour per ton of ice are required for this purpose. With condensing water of 90 to 95 deg. it is not possible to run on less than from 20 to 25 lb. exhaust steam pressure, because of the high condensing pressures necessary. Such pressures would seem prohibitive and yet a plant will be described later which is proving very economical under those conditions.

The absorption machine is the ideal one for warm water conditions when properly designed. Just as it takes very little more coal to carry 125 lb. pressure than 100 lb. (less than 1 per cent), it takes comparatively little more steam in the generator to produce 200 lb. pressure than it does 150 lb. The increase in power required for a compression machine, however, is very marked. An electrically driven compression plant will require from 43 to 70 kw-hr. per ton of ice per day, depending upon its size and other conditions. The former figure can hardly be called normal. At 1 cent per kw-hr. the power costs per ton will usually average between 50 and 60 cents. Table 2 gives figures showing the operating cost of compression machines using various sources of power including electricity. This gives 58 $\frac{1}{2}$ kw-hr. as the amount of current required for all purposes.

From the central station manager's standpoint in the

TABLE 1 COAL AND ICE RECORDS, MUNCIE ICE & COAL CO. MUNCIE, IND.

depreciation on the boiler plant, the total power cost should not exceed 35 cents.

It is entirely possible, however, in a properly designed compression and absorption plant, say of 80 tons capacity, with a 20 ton machine of the former type and a 60 ton of the latter, to make ice at a fuel cost even lower. In this case, there should be two 40 ton tanks, the compression machine being used on one-half the coils of one tank and the absorption machine on the others. The exhaust from the compression engine and auxiliaries furnishes the 3600 lb. of steam per hour required for the generator and the absorption machine, making raw water ice with coal at \$2.00 per ton, at an evaporative efficiency of only 6 to 1; 6½ tons are required and the fuel cost is 16 cents per ton. Such an 80 ton plant could be run on a 125 h.p. boiler and with a second boiler in reserve, the cost, including interest and depreciation, etc., and labor will hardly be more than 30 cents per ton, if that. There will be plenty of distilled water for filling cores, and distilled water ice can be made at a slightly increased cost.

Of course, if a suitable neighbor could be found requiring a certain amount of power and heat and having no use for the exhaust steam, a straight 80 ton absorption machine

could be installed. By using the expansive force of the 4800 lb. of steam per hour, required by the generator, in an economical unallow engine, current could be sold, not bought, which would further reduce the operating cost.

To show the possibilities for profit in a properly designed combination plant, owned by a central station, reference will be made to a plant in a southern city of about 50,000 inhabitants, where the conditions are so trying that if a combination plant can prove profitable there, it would anywhere. This plant was installed in 1912, under the direction of Sargent & Lundy, consulting engineers of Chicago, and has proved satisfactory to all concerned.

The old company had been in the ice business for a number of years, having a 50 ton compression machine with two 25 ton tanks, each containing 412-300 lb. cans. At one end of the old building they also had a 2,000 ton storage house which had never been insulated or used. In addition they owned a second compression ice plant with independent steam plant, of 25 tons capacity, located a mile or more away and operated as a separate unit from May to September. A spray pond was used for cooling condensing water for both the condensing engine and the ice machine. The fact

that the temperature of this water reached 95 deg. and sometimes over, had greatly reduced the output of the 50 ton plant as well as increased the cost of manufacture. In fact, hardly more than 38 to 40 tons of ice had been made daily on the two tanks previously mentioned, and the operating cost was considerably over \$2.00 per ton. It is only fair to say, however, that as the new owners contemplated a change, the plant was not in as good condition as it should have been.

It was decided to increase the output to 100 tons and the original plans contemplated the addition of 50 tons more tank capacity and either electrically driven compression machines at the old plant, or compound condensing machines of 100 tons capacity at the new. The engineers, however, wisely decided to insulate the ice storage house which would give 40 tons extra capacity daily for fifty days, during the

summer peak, and they put in an exhaust steam Carbondale machine of the atmospheric type, guaranteed to make 60 tons of ice on the two tanks and cool the storage house. The old 25 ton plant was abandoned and sold. The condensers, absorbers, weak liquor coolers and rectifiers are located on the boiler house roof of the new plant. In this connection, it may be of interest to know that this exhaust steam machine was added without increasing the size of the power plant building, while same would have had to be extended at a cost of \$12,000.00 if a compound condensing compression machine had been selected. Preliminary estimates showed that ice could be made in this plant at an operating cost not exceeding 45 cents per ton.

Fig. 4 is an interior view of the turbine room in the new power house, showing one of the two 2500 kw. turbines which, of course, is run condensing. In the foreground is a 75 h.p. Terry turbine direct connected to a centrifugal water

* Enlargement of ice storage necessitated purchase of abnormal amount of ice in order that the house would be filled before the summer season.

** Plant No. 1 broken down and tank room being overhauled. Plant No. 2 was inoperative necessitating purchasing practically entire supply.

circulating pump, which was designed to run to its capacity with 200 lb. steam pressure and 25 lb. back pressure; under these conditions, it was guaranteed to use 70 lb. of steam per h.p.-hour, just 20 lb. more than if it had exhausted at atmospheric pressure into the feed water heater. This is somewhat more steam than the generator requires, and the excess is used in the heater.

Fig. 5 is a near view of the ammonia generator, showing the aqua pumps beneath and the aqua receiver at one side. One of these small pumps is capable of making 75 tons of ice, is automatically controlled and requires little attention. In fact, outside that of pulling and storing the ice, the labor cost in the plant is practically eliminated. The exchangers of the vertical shell type are on the other side of the wall, back of the boilers. All the rest of the machine is on the boiler house roof.

Fig. 6 shows this atmospheric apparatus. There are 28 combined condenser and absorber stands of which the upper

FIG. 5 NEAR VIEW OF THE AMMONIA GENERATOR SHOWING AQUA PUMPS UNDERNEATH

driven compression plant. Table 5 shows the detail of the 41 cents per ton operating cost.

As a rule, it is better to figure on obtaining steam for the generator from one or more of the auxiliaries as in this case. If at times the supply is insufficient, live steam can be admitted through a pressure reducing valve, but it doesn't pay to put back pressure on a large engine for a small ice plant.

With well water, it is entirely possible to operate the generator on from $1\frac{1}{2}$ to 3 lb. pressure. While it is perhaps advisable to use the exhaust from the auxiliaries in condensing plants in all cases, it is entirely possible to bleed sufficient steam from an intermediate stage of a condensing turbine. A 2500 kw. turbine, running at full load with 27 $\frac{1}{2}$ in. vacuum, used 14.85 lb. of steam per kw.-hr. When the turbine was operated under the same conditions, except that 5000 lb. of steam was extracted per hour, at from 2 to 5 lb. pressure, 16.32 lb. was used. This is an increase of 3675 lb. per hour and, as this 5000 lb. of steam so extracted will make 85 tons of ice, the extra steam would amount to

FIG. 6 VIEW OF THE ATMOSPHERIC ARRANGEMENT OF CONDENSER AND ABSORBER STANDS

ten pipes are condensers and the lower twelve absorbers. The rectifiers and weak liquor coolers can be seen in the rear. The weak liquor enters the mixer through a jet helping to pull in the gas. During the winter one-half of these stands will make capacity and only 55 lb. pressure is required on the generator, materially reducing the steam consumption.

Table 3 shows the ice produced and sold for the past seven years by this company, the new machinery having been started August 10, 1912. In this connection, it should be remembered that up to 1912 the figures include the output of the 25 ton independent plant.

In January 1914 the roof of the storage house was raised so that ice can be piled 60 ft. high, increasing the capacity to 5,000 tons. In spite of this extra refrigerating load, the plant averaged 70 tons of ice during the hot summer months and 60 tons for 365 days. The credit of this is due, not only to the machine, but to the fact of unusually capable management.

Table 4 shows the output and operating cost for 1914. Even with 95 deg. water and a tank 500 ft. away from the machine the entire average operating cost for the year is less than the power cost alone in the privately owned electrically-

43 lb. per ton of ice per hour. This is over twice the extra steam required from the plant just described. If the above engine is operated at half load, and 5000 lb. of steam per hour is extracted, 16.8 lb. will be used. This will be 2437 lb.

TABLE 4 PRODUCTION DATA FOR CALENDAR YEAR 1914

of steam extra or 28½ lb. per ton of ice per hour. It is, therefore, more economical to bleed such a condensing turbine at half rather than full load, but in neither case as economical as where exhaust is taken from non-condensing auxiliaries.

If the turbine had been running at full capacity condensing and the current used for driving an electrically-driven compression machine, about the same amount of extra steam would be taken from the boilers to make 85 tons of ice as would be required for an absorption machine of this capacity bleeding steam from the turbine. However, in the first case, the output of the turbine would be decreased by the amount of current used, while in the latter its entire capacity would be available for commercial purposes.

In conclusion, it may be said that central station managers, owning their own ice plants, where properly designed, are finding such plants far more profitable than the lighting plant itself. In fact, in some of the smaller cities, where the light plant was operated alone at a loss, the combination has turned the same into a source of profit. In many small towns the water and light plants are combined, in which cases the water is first used for the ice machine and afterwards turned into the city mains. There can be no question about the future of the properly designed combination plant.

DISCUSSION

E. W. LLOYD¹ in discussing this paper said that three or four years ago when it became necessary for the central stations in Chicago to secure additional power loads in order to meet a new rate schedule, the refrigerating business presented itself as the most promising. Experience has justified this promise and in the past three years the number of plants thus operated has been increased from one to eighteen, and at present a third of a million tons of ice, or ten per cent of the city's total requirements, is being made with central station power. The chief interest is in raw water ice plants which are the best where the public water supply is pure. The annual load factor is about 45 per cent, though in exceptional cases it may rise to 65 per cent. The kilowatt hours per ton is quite variable, depending somewhat on the size of the cans. Experiments are now being made to determine the best ratio. We sell power for ice making at one cent per kw.-hr., which is feasible on account of the low increment cost of taking on the business of this class.

SOME ENGINEERING PROBLEMS ARISING IN THE TRANSPORTATION OF NATURAL GAS

BY JAS. P. FISHER, BARTLESVILLE, OKLA.

Member of the Society

NATURAL gas occurs in certain portions of certain strata of the earth's surface in areas of comparatively limited extent. It is used as fuel, for the most part, in centers of population and industrial activity. The fields where the gas is found usually happen to be at considerable distances from the points of consumption, making it necessary to lay pipe lines for transporting the gas. The designing, building and operation of these transportation systems give rise to many problems of an engineering nature.

In the earlier stages of the industry, the greatest difficulty was experienced in constructing a pipe line sufficiently good and cheap to make the commercial transportation of gas feasible for any great distances. As better pipe line, pipe couplings, compressing equipment and measuring equipment have been developed, it has been made possible to transport gas successfully over greater and greater distances. The limits in improvement in equipment and in knowledge of conditions have not yet been reached by any means, so that the present distances of transportation are in no way final.

In the beginnings of the industry no supply of suitable pipe was available, and the joints between sections were so imperfect and prone to leak that it was found commercially impracticable to transport gas through a pipe for more than a very few miles. Various types of pipe lines were tried. Some lines were laid with cast iron pipe, with bell and spigot joints caulked with lead. These lines were fairly good for moderate pressure, but were very expensive to lay. Their high cost and the proportionately low pressures permissible made them unsuitable for any great length.

Lines of steel or wrought iron pipe with screw joints were the first used to any large extent. In some of the earlier lines, the joints were made with a straight thread; but it was very soon found that the taper thread was greatly superior, both in strength and tightness. Some very extensive transportation systems were laid with pipe joined in this way, but a number of serious difficulties arose, the greatest of which was that of making a line reasonably free from leakage. This leakage became greater with increase in length of line, and also with increase in pressures carried, and put a commercial limit on the distance that it was profitable to transport gas.

When it was necessary to increase the carrying capacity of a line, pipe of larger diameter was laid without attempting to materially increase the pressure carried. This led, in some instances, to lines of enormous diameter. One line was laid into Pittsburgh 36 in. in diameter, of steel riveted pipe joined by flanges throughout its length. Such construction was exceedingly costly; and, when it is remembered that the field to which a line was laid might not last more than a few years, it is seen that a better arrangement

Presented at the sixth annual meeting of the University of Kansas Student Branch of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on February 18, 1915.

of pipe line was very badly needed. It was not found practicable to make threaded joints in pipe larger than 12 or 14 in. in diameter, and even in pipe of this size it was found to be difficult to make tight joints.

Several different types of wrought iron pipe joints made by calking with lead were tried. Lines laid with such joints were tight at first, but any motion of the pipe from settling of the soil or temperature changes was found to make them leak badly.

Temperature changes were also found to be a destructive element in a line of pipe connected by threaded joints. Lines laid in the summer often pulled apart in the winter. Where such joints are now used, the lines are laid in cold weather if possible.

To meet these difficulties a new type of coupling was developed, consisting of a center piece, which slipped over the ends of the two lengths of pipe to be joined, two glands or end rings, two rubber packers, and connecting bolts between the two end rings, the whole forming a double stuffing box arrangement. This coupling proved to possess many advantages over any form of joint previously used, and with it lines that were very nearly free from leaks, if sufficient care was taken in their construction, were found possible. Lines could also be made of lighter pipe and still carry the same or higher pressures than was possible with the threaded joint. This improvement has greatly increased the distance it is possible to transport gas profitably; and, although the joint has many grave weaknesses, it is the best available at the present time.

Recently there have been some short lines laid in which the pipe was welded together end to end. This practice is too new to prove its success, but it seems to promise the solution of difficulties due to leakage and deterioration of the rubber-packed joints now commonly used. Like pipe joined by screw joints, the line will be subjected to heavy strains due to temperature changes, and it is likely that special provisions in expansion joints will have to be made for this condition.

In the early days, the natural pressure of the gas as it occurred in the fields was the source of power used for its transportation. As the fields neared exhaustion, or when the distances from the fields to the points of consumption were too large, the pressure fell too low, and it became necessary to increase it artificially by means of compressors of one type or another. In many of the earlier plants attempts were made to locate these compressors in the towns and draw the gas through the lines by suction. As could have been easily predicted theoretically, these attempts failed, and it became the practice to locate the stations in or near the fields. At the present time practically every gas transportation company has to keep up a system of compressing stations in order to properly maintain and control the amount of gas passing through its lines.

Most of the larger natural gas systems of the country have been the result of a process of evolution in which lines were extended farther and farther to reach one field after another, and in which one compressing station after another has been built, usually for the purpose of putting gas from a declining local field into the main trunk line. Another factor in this evolution has been the necessity of small companies combining in order to be able to go to greater distances for a common additional supply when the old sources of supply were exhausted. As conditions have changed,

some of the equipment becomes useless in its present location, and sometimes it is possible to so alter lines as to utilize old equipment for a new purpose.

The Cushing field is one of the main sources of supply in the mid-continental region. When first developed this promised to be a long-lived source of supply. At that time, however, the gas was found mostly in the Wheeler Sand, at a depth of about 1500 ft., and some oil was found with it. The presence of oil in a field is always somewhat of a menace to the life of the field as a gas supply. This is largely because it is cheaper and easier to produce the oil and allow the gas to waste to atmosphere. When oil wells are so situated as not to be convenient to a gas line, the gas is not marketable, and is considered as a by-product of small value by the oil man. In a great many instances oil can be produced without pumping by simply allowing the gas pressure to blow it out.

In the Cushing field, oil and gas were discovered in a deeper sand several months after the taking of gas from the field had been begun. This caused an exceedingly active development of the deeper sand for oil, and enormous quantities of gas were allowed to waste to the air. Not only this, but in a great many instances the wells were so carelessly cased and packed that the higher pressure gas in the deep sand followed up around the casing to the lower pressure strata above, where it was dissipated and was no longer available for commercial purposes. By proper means, it is possible to drill the oil wells and produce the oil with scarcely any waste of gas, but it costs more.

It is estimated that the gas escaping from the Cushing field is about 400,000,000 cu. ft. per day, or about 11,000 tons per day. This would be equivalent in fuel value to a train load of coal of 300 to 400 cars of average capacity. Of the gas in this field, only about 10 per cent ever gets into a pipe line or is used as fuel. The problem here is mostly one of proper government and control, so far as the community at large is concerned, and financial, so far as the transportation company is concerned.

As the gas in the Cushing field comes from the well, it is very far from pure or a perfect gas. It is composed largely of methane, with considerable quantities of the heavier hydrocarbons, ranging from ethane through the C_4H_{10+} series, including those which at ordinary atmosphere conditions are vapors and are considered as part of the gas proper, down to heavy oils, and often salt water. The liquids are held in suspension as a fog or mist, or run along the bottom of the pipe and collect in low places. Between these extremes are all those compounds usually known as gasoline or kerosene or diesel oil. Dirt, sand, etc., are also often present.

The first problem in the transportation of this gas was to separate dust and dirt, and such liquids as water, oil, or gasoline. For this purpose drips or separators were provided in the lines from the wells to the main trunk line. These drips vary widely in design, but are all intended to catch and store the water and oil until the patrol man can blow the line out to the atmosphere. The simplest drip is a Tee with the opening down, and one or two joints of pipe connected on as storage for the liquid that accumulates. This serves fairly well for any liquid not held in suspension in the gas, but, of course, does nothing towards removing the suspended liquid. A great many attempts have been made to remove this suspended liquid, usually by a separator working on the centrifugal principle; but it is a very

difficult matter, indeed, to remove the last traces of liquid in this way, and, so far, efforts in this direction have only been partially successful. A new type of drip has recently been developed in California, but it has not as yet been fully tried out.

Any liquid not taken out by the field drips tends to collect in low sections of the line, and drips should be provided at all these low points. If pockets of liquid occur in the line, they cause the flow of gas to be pulsating instead of steady. This pulsating is difficult to overcome entirely, and is one of the chief sources of trouble in the operation of measuring stations.

Gasoline and oil are the main cause of rapid deterioration in the joints in the pipe lines, which are usually packed by rubber or composition rings. The oil and gasoline attack the rubber rings quite actively, and sooner or later cause leaks and blow-outs, especially as the pressure carried in the line is from 200 to 400 lb. per sq. in. Several substitutes for rubber are being used and seem to be more resistant; but the only way to eliminate trouble from this cause is to keep gasoline and oil out of the line.

FIG. 1 CURVE INDICATING RELATION OF DISTANCE BETWEEN COMPRESSING STATIONS TO POWER REQUIRED

Gas entering the main trunk lines is often measured by orifice meters, and many points come up in connection with the practical use of these. In order to compute the amount of gas passing an orifice meter at any instant, it is necessary to know: *first*, the temperature of the gas; *second*, its gravity; *third*, the size and coefficient of orifice; *fourth*, the absolute pressure of the gas passing the orifice, and, *fifth*, the differential or drop of pressure in the gas in passing through the orifice.

The temperature is quite constant at any given time of year, and a mean temperature for the year is usually the contract basis on which gas passing a measuring station is computed and purchased.

The gravity of the gas is quite variable, even for gas coming from a given field; and when it is considered that gas passing a measuring station may come, in varying proportions, from several fields, the importance of making frequent determinations of the gravity of the gas passing a station to ensure accurate metering is evident. The gravity of gas varies in practice from 0.59 to 0.72, taking air as unity. It is determined by comparing the time for a given quantity of gas to flow through a small orifice with the time required

for the same volume of air to pass the same orifice with the same head causing flow, and computing from the

$$\text{formula } G = \left(\frac{t_{\text{gas}}}{t_{\text{air}}} \right)^2$$

So far as the writer is aware, nearly all gas companies, as well as companies manufacturing orifice meters, have been inclined to assume this gravity factor constant at 0.60 or 0.64. In all orifice meter measurements, as well as computations of line flow, or of Pitot tube measurements, corrections should be introduced for the gravity of the gas. In most of these computations the quantity will vary inversely as the square root of the gravity.

An idea of some of the problems incident to a compressing station may be obtained by a consideration of a typical compressing station of approximately 3000 h.p., which is capable of compressing about 40,000,000 cu. ft. of gas per 24 hours through 3 compressions and delivering it at 350 lb. gauge pressure. Up to this station the gas is transported by the natural field pressure. The prime function of the station is to re-compress the gas, which has dropped to a pressure too low for economical transportation, to a pressure high enough to deliver the requisite quantity through the remainder of the line to the points of consumption.

One of the chief problems is that of the condensation of gasoline in the line beyond the station. As the gas leaves the field, its pressure has been diminishing and its capacity for carrying gasoline as a vapor increasing. There is, therefore, little danger of deposit of gasoline in the line between the field and the compressing station. In this 40 miles of line practically all liquid has been removed by the drips along the line.

At the compressing station the pressure of the gas is raised to 300 lb. per sq. in. or higher, and its temperature raised to from 210 to 240 deg. Fahr. After compression, the gas is passed through a cooler consisting of a large number of pipes in an open pond of water. Only occasionally is the temperature in the cooler low enough to condense out any great proportion of the vapors condensable at this pressure and line temperature. A separator is provided at the outlet of the cooler, but it can only take out vapors already condensed. It is, therefore, apparent that there is a possibility of further condensation of gasoline in the pipe line beyond the compressor station. This is exactly what occurs, and it causes a heavy depreciation in this part of the line. In one case, gasoline taken from a drip beyond this station was used in an automobile, and it was found that the exhaust smelled very strongly of burnt rubber. This would not ordinarily matter were it not for the fact that this same rubber has been dissolved out of the pipe joints, where it is very greatly needed.

From a theoretical standpoint it is entirely possible, by well-known processes, to condense and separate this gasoline before it enters the line. When it is considered, however, that there are 800 or 900 tons of gas passing this station per day, and that the gasoline content is very small, it is seen that the equipment necessary would involve a considerable investment, and the problem becomes a commercial one of whether or not the necessary equipment can be installed with an investment small enough to be profitable. This last problem will be special for each particular case, and is one which in most instances has not yet been solved.

Continuous accurate measuring of all gas into and out of the whole system is one of the perpetual problems of operation of any transportation company. In order to safeguard against loss due to the failure of any of the measuring apparatus, it is necessary to check up in all possible ways the quantities of gas passing meters. In some cases this can be done by line flow formulae, and in some by the displacement of compressing stations. It is found necessary and advisable to use both these methods whenever possible. The pipe line formula used is of the form $Q = K\sqrt{P_1^2 - P_2^2}$ where Q is the quantity of gas, and K is a constant depending on the length and diameter of the pipe line and the gravity and temperature of the gas. The formula for flow of gas through an orifice meter is of the form $Q = K^1\sqrt{hP}$ where K^1 is the constant of the orifice meter. In checking a meter by line flow formulae, the quantity involved is the same; therefore, by equating the two expressions and reducing, the expres-

sion $\left(\frac{K^1}{K}\right)^2 = \frac{P_1^2 - P_2^2}{hP}$ is derived. The ratio of the squares

of the constants for any line and meter can be evaluated and is a constant. To check the meter against the line flow formula, it is then simply necessary to evaluate the expression

$\frac{P_1^2 - P_2^2}{hP}$ and compare it with the constant derived

as above. This check is so simple that meter station operators can easily make it and report the meter out of order, if the value figured is found greatly different from the constant.

It is well to point out here that if observed pressures are correct, the pipe line formula can never show an amount of gas passed less than the actual, but is apt to show a greater amount, due to excessive pressure drop from leakage or an obstruction in the line. The displacement of a compressor station gives a basis for comparison with the quantity of gas as shown by a measuring station which may show up defects in the operation of either. If the amount of gas measured would involve a volumetric efficiency of the compressors greater than 90 per cent, it is a very safe guess that the measuring station instruments are over-measuring the gas.

One very important function of a natural gas line is the equalization of the rate of production. The demand for gas in a city varies greatly from hour to hour of the day, being several times as great in the daytime as at night, and also varies greatly with atmospheric temperature. It would be a difficult matter to vary the output of a compressing station or a field at a distance from a town to meet the widely varying demand, if it were not for the equalizing effect of the transmission line. When the supply is greater than the demand, the gas is being stored in the line, and is available when the demand suddenly becomes much greater than the rate of supply. Often this equalizing effect will enable gas to be taken into the line at a uniform rate from the field for days at a time, while the demand at the other end of the line is fluctuating widely. The adjustment of supply to demand over the whole of a large system is an art in itself. It demands that all production shall be regulated from a central

point by a dispatcher, who is in constant communication with all points of demand throughout the system.

Finally, regarding the problem of transporting gas by means of pipe lines and compressing stations, our gas fields are not only stores of latent energy in the form of fuel, but also stores of latent energy directly available as power in the highly compressed state of the gas. At present the pressure energy is used quite wastefully in the transportation of the gas itself. If, instead of allowing the pressure of the gas to drop to a third or a fourth of its initial value before re-compressing it, the pressure could be maintained at a high point, a great reduction in the total power required to transport the gas could be made. This would point to smaller compressing stations located at shorter intervals along the line. These stations would require less total power than stations at greater intervals performing the same service, and they could be simplified greatly by the omission of the after-cooler, as the smaller range of compression would not

FIG. 2 CURVES SHOWING POWER REQUIRED FOR TRANSPORTING GAS AT DIFFERENT PRESSURES AND VELOCITIES

raise the temperature of the gas to an objectionable point. The curve, Fig. 1, shows the economy in power possible by more frequent stations operating through a smaller pressure range.

The curve in Fig. 2 has been prepared to show the relation between the amount of power required to transport different quantities of gas, the pressure at which the gas is transported and its linear velocity. In this case, the power is assumed to be applied at such frequent intervals along the line that the drop in pressure between the points of application of the power is only 5 per cent of the initial pressure. In other words, the pressure is maintained nearly constant, and the power applied represents the friction loss in the line at the pressure shown. It is seen that both the power required and the amount of gas vary directly with the linear velocity of the gas in the line. Also, that the power required to transport a given quantity of gas decreases very rapidly as the pressure at which it is transported increases, showing that there would be great economies possible if we could make our lines more perfect, so that higher pressures could be carried safely and without excessive leakage.

METAL SPRAY PROCESSES IN ENGINEERING AND ART

BY JOHN CALDER, BOSTON, MASS.

Member of the Society

ONE of the great metallurgical problems of the day has been to produce a non-corrosive surface on iron and steel, the indispensable but vulnerable materials of engineering construction, without affecting the physical properties of these metals or the shape or usefulness of the object treated. This has been attempted by chemical, electro-chemical, and mechanical methods. Tinning, galvanizing and sherardizing are the ordinary wet and dry chemical methods of applying a protective metal coating directly to a considerable volume of engineered and manufactured product but these processes are narrowly limited in the variety of their applications. In the other chemical processes the iron and steel surfaces have been deliberately attacked by chemicals to form from them stable, adherent compounds as a protective overlay which preserves the remainder of the object from corrosion. This is the general method of what are known as the "rust-proofing" processes.

Plating, the electro-chemical method, furnishes a continuous thin metallic web around iron or steel objects submitted

the deposits are not easy to control in the matter of location, quality and thickness. The permanence of the resulting adhesion is not assured and many of the coatings rapidly deteriorate.

There are demands in the arts for a method which will take the process to the work to be coated or to any part of it, and will secure the quick deposition on any coherent object, whether metallic or not, of any desired metal or alloy in any quantity, however minute. Inventors have labored over the problem for many years but commercial results have not been developed until recently because of the lack of economy in the earlier forms of apparatus, and even yet, the whole range of metals is not available. Effective pulverization of the very hardest metals still presents economic difficulties but lead, tin, zinc, aluminum, copper, nickel and their alloys can now be sprayed easily and these metals cover very well the practical range of protective coatings.

The overlaying of iron and steel for temporary effect with non-metallic substances such as paints, enamel, japan, and varnish has been the mechanical method necessarily followed hitherto for the great bulk of metal objects and structures and the renewal and maintenance of such protections involve enormous outlays. It is the object of this paper to describe the latest mechanical process, the Schoop process, for depositing electro-positive metals on iron and steel. Incidentally, the method permits the depositing of many other metals and alloys on coherent bodies whether metallic or not.

The process takes its name from M. U. Schoop, an engineer, of Zurich, who, in collaboration with other inventors, made the metal spray an effective coating agent. In the Schoop process, for which the United States patents have just been issued, the coating metal adheres to the object chiefly by mechanical union. The metal is discharged in hot impalpable particles moving with high velocity and these when directed upon a prepared object penetrate the pores of the latter while the spray is still plastic. The coating metal thus dovetails itself into the superficial pores of the object and does so in the presence of reducing gas which prevents oxidation at the junction of the metals.

The progress of invention on metal spraying has been chiefly directed toward making the metallic particles as small and as hot as possible, thereby avoiding oxidation, and reducing the pressure of air used and the cost of the gases employed. In 1902, Thurston was granted a patent (United States No. 706-701) for impacting, with unignited gas, metal in the form of dust upon a metallic base. His apparatus was not practical and no commercial results were obtained.

Within the past year, four United States patents have been issued which embrace all the important steps since Thurston's invention. Schoop invented (U. S. No. 1,128,058) a process for producing a fine spray from either molten or solid metal and also for producing separable metallic coat-

FIG. 1 DETAILS OF APPARATUS USED FOR THE EARLY LIQUID METAL SPRAYING PROCESS

to it, provided the shape and size of the article are suitable. It is necessarily limited to small objects. The adhesion of the plated coating is slight and its continuity is essential for service. The tinned or galvanized coating adheres, due to chemical affinity for clean iron, but its irregularity gives much trouble. The dry zinc galvanizing, known as sherardizing, gives a better result but is limited to the application of one metal under heat conditions, which confine it largely to black work and to objects the distortion of which is of no consequence.

None of the processes which have been briefly mentioned meet the general needs of the arts in a satisfactory way as they involve the exposure of engineered and manufactured products to injurious action from moisture, chemicals or heat. They admit of depositing only on metallic or metalized surfaces and they can apply but one or two metals out of the whole range of such elements and their alloys. They must ordinarily be applied to every part of the object and

Presented at the New York local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on May 11, 1915.

ings or copies of the objects sprayed upon; this was known as the liquid metal spraying process. He later invented (U. S. No. 1,128,059) a process for projecting finely divided unmolten metal particles on to a surface, using an ignited gas and metal in the form of dust like Thurston; this was known as the metal dust spraying process.

Very soon afterwards Morf invented (U. S. No. 1,128,175) a process for melting, atomizing and projecting, practically simultaneously, solid metal and particularly metal in the form of wire; this was known as the metal wire spraying process. At the same time he also invented (U. S. No. 1,100,602) a successful apparatus (known as a "pistol") for effecting this process. These inventions above outlined form the basis

FIG. 2 PORTABLE APPARATUS FOR THE METAL DUST SPRAYING PROCESS

of the Schoop metal spray process as it is now operated in the United States.

The evolution of the apparatus has been interesting. The liquid metal process involved a large non-portable reservoir of hot metal weighing with the auxiliary parts over a ton; the metal dust apparatus weighed over a hundred pounds, while the "pistol" of today weighs less than four pounds. Figs. 1, 2 and 3 show the three forms through which the apparatus has passed.

In the apparatus represented by Fig. 1, a molten metal is allowed to run continuously from the reservoir *R* through a broad nozzle *X*, where it is broken up and swept away by a violent current of heated gas *G*, issuing under regulated pressure from containers *C* and reheated in its passage at *H*. The expansion of the gas chills the molten particles and forms a rapidly moving spray or fog of metal which impacts upon any object placed in its path and plates it.

Any metal fusible under the conditions of the apparatus can be used and owing to the low temperature of the fog, it

is possible to plate very delicate and easily combustible objects, as well as metal articles. Aluminum plating, which could not be obtained by fusion or electrolysis on account of its ready oxidation, was easily obtained by this Schoop process.

The obvious objections to such an apparatus were lack of portability and the expense of melting and keeping fluid most of the metals in the unavoidable intervals of spraying. The result was that only the more fusible metals, lead and tin, were used where spraying on a continuous scale was possible and the liquid metal apparatus was never reduced to economical practice. It was observed with this apparatus, however, that the particles were not actually molten at the moment of impact and this suggested the next step.

Fig. 2 represents the second form of apparatus in which portability was secured and the metal particles to be sprayed were prepared in advance. Powdered metals in a very fine state of division have many of the characteristics of a liquid. Their fine particles mix with one another like drops,

FIG. 3 EARLY FORM OF THE METAL SPRAYING "PISTOL"

they spread with facility and unite under the influence of very little force. The metal powder in the container *C* is entrained in an air blast *A*, heated in the flame of a blast pipe *B*, and projected with high velocity. The gas is burned at *D* and the supply of air is regulated at *S* to obtain complete combustion.

It was found that the anticipations from the use of the first apparatus were correct and that metal particles projected in a pasty condition produced plating as before. Most metal powders, however, tend to oxidize rapidly and the use of this apparatus was practically restricted to tin and zinc on this account. Even with tin, the expense of metallic powder was prohibitive, but the plating with tin and zinc was very good. In the case of zinc, the apparatus known as the cyclone is still the most economical instrument for plating large surfaces with that particular protective metal. Zinc dust is a by-product in the stacks of zinc smelteries. With the Cyclone apparatus, it can be impacted on steel structures either in the field or at the factory.

Inventors then set themselves to overcome both the chemical and economic difficulties, viz.: to dispense with mass melting and dust preparation and to secure instant and simultaneous operation of melting and pulverization, and control with a handy, economical and easily transportable

appliance. The result was the ingenious instrument known as the "pistol" which is shown in Fig. 3.

The principle involved consists, as shown in Fig. 4, in feeding a fine wire *W* of any metal into a reducing flame zone *Z* at such a constant speed that the position of the end of the wire *E* remains stationary, the melting rate being exactly equal to the rate of feed. Under such conditions the wire end melts a drop at a time and each drop at the instant of formation is struck a violent blow by an air blast *A*. In other words, the pistol is a machine gun which automatically manufactures its ammunition from a reel of wire and bombards the object to be plated with plastic projectiles of extremely small size.

The resulting fog or spray of fine metallic particles into which the drops are divided takes the form of a diverging cone *C* with a core of reducing gas *G* in which the particles are entrained, and a surrounding sheath of air *A* which is rapidly expanding and cooling. Any suitably prepared ob-

FIG. 4 DIAGRAM ILLUSTRATING APPLICATION OF REDUCING FLAME TO METAL WIRE IN THE PISTOL.

ject placed in the path of this metallic spray is plated through impact without undue elevation of temperature.

Fig. 6 shows a section of the commercial spraying pistol now in use. The principal parts of the pistol consist of an outer casing *A*, cast of aluminum, with a central projecting tube forming a handle, a wire feed mechanism mounted entirely upon the cover *B* of the turbine chamber, the turbine *C* actuating the wire feed mechanism, gas, air and wire nozzles mounted upon the outer casing held in position by a hand nut *D*, and a removable cover *E* which completes the enclosure of the outer casing.

Gas and air ducts are drilled in the outer casing. The flow is controlled by the tapered valve *F* provided with a handle *G*. The wire feed mechanism is actuated by a turbine *C* mounted on a vertical shaft running in ball bearings; a worm is cut in the upper end of the vertical shaft and drives by worm wheels the horizontal shafts *N* and *O*, Fig. 6, which are provided with worms in turn driving the worm wheels *P* and *Q*.

The wheels *P* and *Q*, Fig. 6, are provided with slots to engage the projecting lugs of the lower feed wheel *R*. The upper feed wheel *S* mounted in the pivoted frame *T* is provided with shrouds controlling the position of the lower feed wheel *R*. The lower feed wheel can be engaged in either worm *P* or *Q* by raising a clip *I*, shifting laterally in either direction and locked in by the opposite clip. The shift can be readily made by allowing the mechanism to run slowly by a slight opening of the starting valve.

Pressure is applied to the feed wheels through the pivoted frame *T* by a coiled spring, and controlled by the operator by means of the release lever *K*. The final adjustment of the wire feed is controlled by the needle valve *M*, Fig. 6.

The turbine and shaft complete is assembled in the outer case and properly adjusted independently of the other mechanism.

The wire feed is entirely assembled on the turbine cover *D* and, when properly adjusted, is secured in position. The wire nozzle base *V* provides an adjustment for position of wire and gas nozzles, and is secured in position by a headless set screw. The upper end of the stem of the turbine cover is provided with an annular groove, which is engaged by the spring loop *U* and secures the removable cover *E* of the case. Loop *U* provides also a means for hanging the pistol on a conveniently located hook.

The operation of the pistol is as follows: The gas and blast nozzle faces *B* and *C* are securely clamped to form gas tight joints by tightening the hand nut *D*. The end of the central or wire nozzle is then 0.015 in. inside the gas nozzle and the stationary melting point of the wire is 0.03 in. inside the air blast nozzle. The wire diameter used is from 0.0319 to 0.0375 in., except for lead and tin which are used in larger sizes owing to their rapidity of melting.

FIG. 5 VIEW OF A COMMERCIAL SPRAYING PISTOL IN HAND READY FOR USE

The feed gears having been set in mesh at the approximate speed required for the wire selected, the air alone is turned on and the speed tested with a short length of wire. Adjustment, if necessary, is made by the needle valve which modifies the speed 2 ft. per minute plus or minus.

The end of the wire reel is then threaded through the stock receiving tube, between the gripping feed rolls and into the central wire nozzle and the fuel gas pressures from the containers are adjusted by the reducing valves and gauges thereon to the tabular requirements for the metal to be sprayed. The pressures of the fuel gases seldom rise above one atmosphere and hydrogen or Blau gas are the reducing gases usually employed. This gas is now admitted by slightly opening the starting valve and when ignited with a match burns quietly as a pilot light.

The starting valve is then opened up full and oxygen is admitted gradually until the flame zone is established. All back-firing is avoided by keeping the reducing gas always in excess of the oxygen, the ratio being three or four to one. The above movements are made in rapid succession on a

light instrument which can be held in one hand and the spray is started up the moment the constant melting position of the wire is reached.

The spray so established is essentially a metal plating air-brush, the diameter of which 5 in. from the pistol end is about 2 in. Objects to be plated are operated upon by pointing the pistol normally to the surface to be coated at any moment at about 5 in. distance and traversing the pistol across the surface with a regular motion. A single coating is about 0.001 in. thick. The operator's vision easily guides him in

applied to coat a wooden pattern for protection with lead, and in Fig. 8 a cement statuette is being covered with bronze.

Gas bombs with fittings and air at 40 lb. pressure are the only requisites besides the pistol and its hose connections for plating non-metallic objects such as wood, stone, paper, cement, cloth, etc. All metallic surfaces should have the scale cleaned off and their pores opened by preliminary sand-blasting.

It will be seen from Table 2 that 0.001 in. thickness, one square foot in area, can be sprayed with the common metals for a small sum. The total cost for German silver is 3½ cents, for copper, 3 cents, for tin, 5 cents, for brass, 2¾

FIG. 6 DETAILS OF THE COMMERCIAL METAL SPRAYING PISTOL NOW IN USE, SHOWING TURBINE, WIRE FEED MECHANISM, ETC.

distinguishing between the coated and uncoated portions and also between a first and second coat.

Two thousandths of an inch well impacted upon a surface are just as effective as a much greater thickness and of course unnecessary sprayed metal increases the cost, as the latter is directly proportional to the thickness. Not only on the score of economy but also to preserve toughness the coating should be of minimum thickness for the anvil action of the metallic spray on a solid metal object is lost above a few thousandths of an inch thickness and a process of cold working follows which produces a brittle scale readily detachable. In practice this matter is easily regulated.

Fig. 5 shows the pistol held in the hand ready for action with the wire thread in position. Fig. 7 shows the pistol

cents, for zinc, 2 cents, for aluminum, 1¾ cents and for lead 1½ cents per square foot.

Various theories have been offered to account for the plating properties of the metal spray, but it is believed by those putting it to practical use that, except in the few cases where the impacted metals have a chemical affinity, the action of the spray is purely mechanical.

Any metal wire can be sprayed with varying degrees of fineness by the pistol, but a hard metal, such as copper, cannot be impacted with the same degree of adherence upon a solid copper object as it would be upon a more porous cast iron object or upon one of the soft metals such as lead or zinc. The coatings may be ground, polished and buffed like any ordinary metals, but polished sprayings do not offer

themselves as economical substitutes for cheaper and less adherent platings which are deposited in smooth condition.

As metal spraying is essentially a kinetic energy process the degree of adherence obtained in any instance depends upon the relative hardness and porosity of the sprayed metal and its base. For some decorative purposes this is of no consequence, but where stress, wear and chemical action are involved it is quite important to choose the appropriate coating.

In spraying where the softer metal forms the object, the body of it, as well as its superficial pores, will be penetrated by the harder metal with its projectile action. When the condition is reversed the softer spraying metal will fill the open pores of the harder object and key itself into the former in cooling off, but it will not penetrate the solid parts of the body. In either case, however, with proper preparation of clean open surfaces a durable adherent coating is obtainable.

Protective coatings on steel or iron may be either original coatings of the whole of an object or any part of it or local applications with the pistol to repair damage or wear of a coating made by another process. The repair of the troublesome defects on galvanized sheets is an example. The localization of copper deposits on iron and steel for the purpose of the cementation process and for controlling hardening is easily and quickly accomplished by the pistol. The results are reported to be much better than those obtained from the necessarily irregular and soft electrolytic deposits, the area of which cannot be absolutely controlled.

Many engineering structures used in the arts, such as steel and iron tanks, girders and machinery of all descriptions, are subject to the action of liquids and chemicals and corrode rapidly, particularly at joints. It is not possible to plate such structures by any other coating method. In such cases a metal is selected which will resist the corroding agent and

FIG. 7. VIEW OF THE PISTOL AS USED FOR COATING WOODEN PATTERN WITH LEAD

FIG. 8. APPLICATION OF THE PISTOL IN COATING A CEMENT STATUETTE WITH BRONZE

The applications of the process already made are numerous and new ones are being suggested continuously. In this connection it should be noted that, though coatings of all the commercial metals and of their alloys can be made on any other metal, and on almost any coherent object, except articles containing grease, the choice of a metal coating should be conditioned by the service which it has to render.

Spraying a metal so that it plates an object gives the coating metal no chemical properties it did not possess before. Hence sprayed coatings used for protective purposes, rather than for finish or decoration, are restricted for resisting acids to lead, for resisting air, moisture, sea water, and ordinary atmospheric action to lead, tin, zinc and aluminum, and where superficial oxidation of the coating is of no importance copper and its various alloys can be freely used also.

In general the applications of the process may be divided in five groups, viz: protective coatings; bonding or junction coatings; electrical coatings; decorative coatings; detachable coatings. It is with the first three of these that the engineer is chiefly concerned.

is sprayed in the form of wire on all the seams and joints, these having previously been cleaned by sand-blasting.

In many cases the treatment of the joints is sufficient, the solid metal resisting oils and liquids for a long time when the seams are rendered free from attack. Railroad and bridge girders can be handled by portable outfits to protect them from the atmosphere and moisture. This is a large industrial field of application in which lead, tin, and zinc sprayings are used, and proper initial treatment of this kind or in the field during erection dispenses with all need for repeated painting.

Laundry machinery, dairy appliances, water heaters, and similar structures exposed to moisture and chemicals can be protected against corrosion due to electrolysis in many cases by sprayed deposits of zinc suitably located, or may be wholly tinned or galvanized by the Schoop process.

Bonding or junction coatings can be freely applied to brick, metal or porcelain connections with the metal spray. The porosity of stone, both natural and artificial, lends itself readily to this use. The refractory hearths of furnaces using

the surface combustion principle are readily bonded by the Schoop pistol to their porcelain or metal gas-conducting tubes by spraying the assembled parts with a metal of sufficiently high fusing point. Ordinary solders are of no service in furnaces depending upon radiant energy and the refractory cements and mortars will not stand the necessary stresses and wear.

This is a single instance of the possibilities in bonding non-metallic surfaces. Though the pistol coatings are amorphous and vitreous throughout and are not calculated to carry the stresses of ordinary metal parts there are many static uses of metal in which the Schoop coating is useful. The electric appliance field is one of these. Carbon in all its resistance forms can be freely sprayed with copper and that metal can be applied in minimum quantity to any piece or portion of a piece of apparatus.

The most recent electrical application is the construction of condensers, especially for wireless service. The Schoop pistol will spray an adherent coat of copper on ordinary sand-blasted window glass. Two-thousandths of an inch is sufficient to produce a highly efficient and cheap plate much superior to rolled tin foil coverings or galvanic deposits of copper on glass. Lead sprayed on glass also furnishes a very cheap and effective condenser plate.

The decorative coatings are of less interest to engineers, but the field is large and, apart from the coating of baser metals with the bronzes and other alloys, almost any metal can be sprayed freely on naturally porous substances such as wood, paper, cloth, stone, cement, etc., and sprayed coatings can either be polished, treated with chemicals to form various patina effects, or allowed to form a natural patina, thus

securing protection of the material from atmospheric action.

The detachable coatings form an interesting study and have yet to be developed for many of the arts. In all the applications already described the object has been to obtain an *adherent* coating of any selected metal upon a clean sand-blasted metallic surface or upon a clean surface of a naturally porous non-metallic object.

It has been found that if the Schoop spray be turned upon a smooth greased surface of reasonable hardness, the bombarding fog of metal particles will remain upon the surface without impacting and will copy the surface to its finest line or detail. On cooling and tapping this reverse it detaches readily and by using it as a mold and repeating the treatment with a film of grease, a detachable copy of the original object, a coin, medal or any relief subject can be obtained in any desired metal.

The application of these detachable coatings to the printing plate, dental plate and other processes in the arts requiring rapid and accurate reproduction is now under development. It is obvious that copper and bronze of a crystalline hard character would give much greater service than the short-lived plates now used of soft electrolytic copper.

The various possibilities of the spray so far developed are indicated by the samples of its work exhibited and by the demonstrations of the pistol in actual operation. Tables 1 to 3 show the data of gas consumption and total cost of spraying a square foot .0001 in. thick of some of the commoner metals by means of the Schoop pistol; also, the cost of spraying per pound and by the hour and the rate of deposition.

THE ELECTRIC LOCOMOTIVE

BY A. H. ARMSTRONG,¹ SCHENECTADY, N. Y.

Non-Member

THE meeting of the local section of the Society in Chicago held on May 14, 1915, was devoted to the subject of The Electric Locomotive as applied to steam railroad conditions. Addresses were presented by A. F. Batchelder and A. H. Armstrong of the General Electric Company, Schenectady, N. Y., the first speaker discussing the development of heavy electric traction from the historical Baltimore & Ohio tunnel locomotives installed in 1895 to the most recent applications in the Butte, Anaconda & Pacific and the Chicago, Milwaukee & St. Paul electrifications; Mr. Batchelder's remarks were in the nature of an informal talk illustrated by numerous lantern slides. Mr. Armstrong supplemented the first speaker's descriptive talk with interesting comparisons with the steam locomotive as to the selection and rating and his remarks are presented herewith.

The first 47 New York Central locomotives of the S type represent a distinctive type admirably adapted to high speed passenger service. This type is designed to deliver a moderate tractive effort at a high speed, giving a tractive effort of 7,100 lb. continuously at a speed of 56 miles per hour and a one hour rating of 20,600 lb. The driving motors, four in number, are thus able to give an output of 2,200 h.p. for a period of one hour without overheating. The later T type of locomotive, weighing approximately 130 tons, has a capacity of 14,000 lb. tractive effort at a speed of 53½ miles per hour or a continuous capacity of approximately 2,000 h.p. output of the motors. For the one hour period, the output is 2,600 h.p.

The reference to continuous and one hour capacities and also to starting tractive effort may demand the explanation to the steam railroad man that the time element plays a very important part in the determination of the rating of an electric motor. In a steam locomotive, the tractive effort or pulling power is determined by the diameter of the piston and the steam pressure behind it, and the locomotive can deliver this tractive effort continuously provided it has sufficient boiler capacity to supply the quantity of steam demanded and the fireman is sufficiently industrious to keep covered the grate which is supposed to have sufficient surface. With the electric locomotive on the contrary, allowance must be made for the fact that the insulation used deteriorates if heated continuously above a certain amount. It takes a considerable time for the motor to heat up to this dangerous point, thus giving rise to a momentary rating or starting effort, a one hour rating and a continuous rating, the latter being the output which the motors can give continuously without injurious heating. In other words, the steam locomotive engineer is concerned in keeping his boiler hot, while the effort of the designer of electric locomotives is to keep his machine cool.

In the early electric locomotive design there was no such thing as continuous rating. The service which it was called

upon to perform was of an intermittent character, the runs between stops were short and the designing engineers were concerned mostly with the question of starting or accelerating, tractive effort and commutation. Therefore, the continuous rating of the early motors had no place in considering its design. With the extension of electrified lines and more especially with the introduction of the electric locomotive on main steam trunk lines, it was found that the motive power was called upon to deliver a continuous output for long periods at a time, and it became necessary to introduce air-blown or ventilated motors as well as fire proof insulation in order to secure the large output required without exceeding the limitations of space and weight imposed by standard gauge and reasonable diameter of wheels, wheel base and weight per driving wheel. We are therefore designing electric locomotives to-day suitable for the heaviest class of freight and passenger service. Such locomotives are entering into competition with the steam locomotive with a full appreciation of the phenomenal growth and possibilities of the latter as developed during the past few years, as well as a knowledge of the growth in the demands placed upon the motive power to take care of modern high speed passenger and freight train service.

In designing such electric locomotives, the electrical engineer is fully alive to the fact that a steam locomotive has been built weighing 750,000 lb. on drivers and having a total weight of 850,000 lb., and that nearly 90 per cent of the total weight of locomotive and tender is now rendered available for tractive purposes by the development of the Mallet principle to include cylinders placed upon the tender itself. It is also known that the tractive effort of these locomotives has increased from the 40,000 lb., of the early consolidation engines weighing 200,000 lb. on the drivers, to values as high as 160,000 lb. for the latest type of Mallet. It is also known that the introduction of the steel passenger car, together with the need of high sustained speeds of between 60 and 70 miles per hour, call for the hauling of passenger trains weighing over 1,000 tons and provision is made in the latest New York Central electric locomotive to take care of 1,200 tons at 60 miles an hour. Due appreciation is also paid to the results secured with the combination of superheating and simple engine which has so largely replaced the compound. Also the increased capacity afforded with the use of mechanical pushers and fire door openings with hand firing has increased the efficiency of the fireman so that it is now possible for him to throw between 5,000 and 6,000 lb. of coal per hour where previously 4,000 lb. might be considered good performance. Finally it is fully understood that the modern steam locomotive has been so improved as to fuel economy by the introduction of superheating, fire arch and other developments that it is possible to get an indicated horse-power with the expenditure of 15 lb. of steam and less than 2 lb. of coal under the best conditions of operation, and that with the use of mechanical stokers or with oil fired boilers, locomotives are in operation giving 3,000 i.h.p. or more.

Fully appreciating the above facts and the magnitude of

¹ Assistant Engineer, Railway and Traction Department, General Electric Company.

Account of meeting of the Chicago local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on May 14, 1915.

the problem confronting him, the electric railway engineer nevertheless offers in the modern electric locomotive a type of motive power which can accomplish results in transportation which are not possible to obtain with the steam locomotive both as regards tonnage handled, speed on mountain grades and general flexibility and economy in operation. The first large electric locomotive built was placed in operation on the Baltimore & Ohio Railroad in 1895, and it is worthy of note that this was a gearless locomotive and a forerunner of the highly efficient gearless locomotives now in operation upon the New York Central Railroad to-day. The New York Central locomotive, as developed in the later T type, is capable of hauling the heaviest overland passenger trains over any length of track that may be electrically equipped, and with-all at a cost for upkeep, including all labor and material spent in maintenance, of not exceeding $3\frac{1}{2}$ cents

shown of \$240,000 over the cost of steam operation during the previous year with practically the same tonnage handled. The entire first cost of this installation, including all material and labor and contingent expenses as well as interest on money during construction, was approximately \$1,200,000, so that the saving above indicated results in a 20 per cent gross return upon the capital required for electrification. This makes no allowance for the scrap value of more than 20 steam locomotives discarded.

On this road, the heaviest class of freight trains are operated electrically, regular operation calling for the movement of from 3,500 to 4,000 tons behind the locomotives from the Butte Yards to Anaconda, and record has been made of train weights as high as 4,500 tons trailing against a gradient of 0.3 per cent. Each locomotive (Fig. 1) weighs 80 tons, all on drivers, and two such units are coupled to-

FIG. 1 THE 80-TON LOCOMOTIVE UNIT OF THE BUTTE, ANACONDA & PACIFIC RAILWAY

per mile run, as is shown by the records of the New York Central during the operation of the past seven years.

The first railroad in this country to adopt electric freight locomotives having large sustained output capacity was the Butte, Anaconda & Pacific Railway. Some three years ago the construction of 92 miles of the total of 114 miles of track was commenced, being completed for freight operation in May, 1913, and for complete freight and passenger operation in October, 1913. There are still four or five steam engines in operation on Butte Hill, but these will be replaced in the near future, so that in a short time the entire road, or 114 miles of track, will be in operation electrically. The one motive inspiring this installation was economy in operation, and preliminary reports indicated that the savings in electric over steam operation should be sufficient to pay for the investment. In fact, the saving was found to be 17½ per cent upon the capital required to electrify. During the first six months operation of this road, careful detail figures were kept on the cost of electric operation, every item of expense being accounted for, with the result that, prorated over the entire fiscal year, there was a saving

together, operated by one engineer and comprise a complete locomotive handling the above tonnage. At the Butte end, there is a gradient of 2½ per cent against the returning empty cars, and at Anaconda 1.1 per cent grade against which one of the above locomotives hauls 25 cars or approximately 2,000 tons.

This leads up to the subject of the rating of an electric locomotive. The Butte locomotive (Fig. 1), weighing 80 tons, all on drivers, will give a continuous tractive effort of 26,000 lb. at a speed of approximately 16½ miles per hour at full substation line voltage; this corresponds to 16¼ per cent of the weight upon the drivers. Investigation of the locomotive loading regulations on many steam roads operating over ruling grades indicates that it is almost universal practice to assign to a locomotive a trailing load so that the tractive effort at the rim of the drivers, as required on ruling grade, will be equivalent to approximately 18 to 19 per cent of the weight upon the drivers. In other words, from 18 to 19 per cent coefficient of adhesion between driver and rail is now considered good steam practice, and the electric locomotive

rating is closely following this same steam practice. The electric motor, of course, gives a perfectly uniform rotation to the driving wheels, and should thus give something like 10 per cent more tractive effort than the steam locomotive with its reciprocating parts. Continued operation will develop whether this additional 10 per cent tractive effort can be utilized or not. In the meantime, steam practice is being followed in the loading of electric locomotives.

In adopting a coefficient of adhesion of 18 or 19 per cent as the basis of determining the tractive effort required on ruling grades, it is evident that there is left for starting purposes the difference between the above coefficient of adhesion and the slipping point of the wheels, whatever that may be, as determined by the condition of the track. Tests on electric locomotives have shown a coefficient of adhesion as high as 35 per cent, or even more under specially favorable conditions, but it is fair to assume a maximum of 30 per cent

making the sustained continuous output of the complete locomotive, 3,000 h.p. at the rim of the drivers. This locomotive, however, will give a considerably larger output for short periods. For example, it has a capacity of 3,440 h.p. for one hour and even greater than this for short periods. The sustained tractive effort is 72,000 lb. at a speed of 15 $\frac{1}{4}$ miles per hour at full substation line potential.

Compare this electric locomotive with the Mallet engine of approximately the same weight now in operation on the St. Paul road, as shown in Fig. 3, and we find that the Mallet engine has 76,200 lb. tractive effort corresponding to 23.5 per cent coefficient of adhesion, but those of you familiar with the performance of this particular engine know that it toils painfully at speeds seldom exceeding 7 to 10 miles per hour when operating at its full hauling capacity. It is in this matter of higher speed for the same tractive power that the electric locomotive excels. In fact the ques-

FIG. 2 THE DOUBLE UNIT 260-TON LOCOMOTIVE OF THE CHICAGO, MILWAUKEE & ST. PAUL RY.

as available in operation and even 25 per cent may be nearer the average. There is therefore, not much difference between the tractive effort required on ruling grades and that required for starting, and in order to be "fool proof" and capable of meeting the exacting demands of the heaviest kind of service, the electric locomotive should be capable of delivering continuously a tractive effort equal to from 16 to 18 per cent coefficient of adhesion of the weight upon its drivers. The Butte locomotive is therefore rated at 26,000 lb. or 16.25 coefficient of adhesion as its continuous output, and this capacity is sufficient to meet all demands of operation on the Butte, Anaconda & Pacific Railway.

Coming now to the latest type of trunk line electric locomotive, the one designed by the General Electric Company for the Chicago, Milwaukee & St. Paul Railway (Fig. 2) is direct development of the Butte, Anaconda & Pacific both as to type of locomotive and general system of electrification installed. The weight of the locomotive is 260 tons, of which 400,000 lb. are on the drivers. Each of the eight driving motors has a continuous rating of approximately 375 h.p.,

tion of speed is simply one of cost and expediency, as the horse-power output of the electric locomotive can be raised to any value desired without exceeding the limits of track loading.

The St. Paul locomotive, weighing 260 tons, has capacity to haul a 2,500 ton trailing load behind the locomotive on a 1.0 per cent grade at nearly 16 miles per hour without any assisting locomotive. The St. Paul road in Montana and Idaho crosses three mountain ranges, the Belt Mountains, the Rocky Mountains and the Bitter Root Mountains. From Lombard to Summit, in the Belt Mountains, a distance of 49 miles, there is an average gradient of 0.71 per cent and a ruling grade of 1 per cent against which one locomotive will haul a trailing load of 2,500 tons without assistance. Between Pidemont and Donald, a distance of 22 miles to the summit of the Rocky Mountains, there exists a 2 per cent grade against which two locomotives will haul 2,500 tons trailing, the second locomotive being used at the rear of the train as a pusher. A second pusher division exists in crossing the Bitter Root Mountains of Idaho, making only two

pusher divisions in the 440 miles of electrified road from Avery, Idaho, to Harlowton, Montana.

The general design of the St. Paul locomotive, as shown in Fig. 3, comprises a locomotive divided in halves for facility in shop repairs, each half being identical and equipped with four driving axles and two guiding axles. The design is identical with the Butte locomotive except for the addition of the four-wheel guiding truck at each end of the locomotive. One of the reasons for the introduction of the truck is that the same locomotive is thus made available for both passenger and freight service. This does not mean that any locomotive can be used interchangeably at will in both freight and passenger service, but it does mean that all parts of the locomotive are identical whether used for freight or passenger with the single exception of the gearing between motors and driving axles which has a ratio of 4.56 for

efficiency of the locomotive, both electrical and mechanical, is nearly 90 per cent maximum, not taking into account the minor losses in driving ventilating fans and air compressors. When descending heavy grades, therefore, the reversible feature of the locomotive, permitting it to transform mechanical power received into electrical energy, suggests by this means a considerable reduction in the amount of power required to operate the road. It is probable, however, that a power saving of less than 10 per cent will result from the regenerative braking feature of the electric locomotives, and the principal advantage resulting from the introduction of the electric brakes will be to relieve brake shoes and wheels from the dangers attending overheating. To those of you who are familiar with the handling of trains on long and heavy down grades this argument will appeal in full force, as it is not an uncommon sight to see brake shoes red hot as

FIG. 3. COMPARATIVE DATA ON THE ST. PAUL MALLET STREAM AND DOUBLE UNIT ELECTRIC LOCOMOTIVES

freight service and 2.45 for passenger service. This adoption of a uniform type of motive power for all classes of service should result in affecting a great reduction in the cost of maintaining the locomotives of the four engine divisions electrified.

A second type of light locomotive for shifting service may be introduced later, although in this connection arrangements are being made to operate independently one-half of the through locomotive by equipping it with draft gear in place of the articulated joint joining the two halves. This will provide a locomotive weighing 130 tons having 200,000 lb. on the drivers and capable of doing one-half the work stated above as the capacity of the combined locomotive, this half locomotive requiring turning if used in passenger service, as it has guiding axles at one end only.

The installation on the St. Paul road will use for the first time on such a large scale a principle which should be of the greatest advantage in the operation of mountain grade divisions, that is, the utilization of the motors on the locomotives to brake the train on down grade and return the energy of the descending train back into the line. The effi-

ciency of the locomotive, both electrical and mechanical, is nearly 90 per cent maximum, not taking into account the minor losses in driving ventilating fans and air compressors.

In regard to the suitability of the New York Central gearless type of locomotive for passenger service, it has been pointed out the entire absence of mechanical losses in the motor other than the brush friction on the commutator, but the facts are so important as to bear repetition. There are no bearings on the motor of any kind as the armature is mounted directly upon the driving axle and the field structure is part of the frame which is carried upon the journals. The electrical efficiency of the motor and the frictional losses on the commutator due to the brushes are therefore the only losses to be considered, and the efficiency of this locomotive in operation is therefore between 93 and 94 per cent. In other words, of the electrical input received at the third rail shoes, from 93 to 94 per cent appears as useful mechanical output at the rim of the drivers. This in itself is a most remarkable performance, but the value of this high efficiency locomotive is rendered more important when it is explained that the maximum efficiency occurs at approximately the free running speed between 50 and 60

miles per hour. In other words, the motor has a drooping efficiency curve, being highest at free running and lowest at overloads or during acceleration, and in this respect being just the reverse of the efficiency curve of geared motors which reach their highest point at practically the one hour load capacity of the motors. The gearless locomotive is therefore particularly adapted to operate on fairly level profiles and could not be utilized to such great advantage on roads like the St. Paul which contains many heavy grades sustained over long extent. It is very difficult to combine in one structure motors capable of hauling 800 tons trailing over heavy sustained grades, and also have the characteristics required for good operation on level track at 60 miles per hour, and in the St. Paul locomotives recourse to gearing between motor and driving axle appears necessary to secure the greatest all around advantages at the lowest first cost.

In answer to the questions asked, it may be said that the control used is an adaptation of the multiple unit control in use on the elevated systems. It permits the operation of the double locomotive from one master controller located in the operating cab of the leading half locomotive; it also permits running two locomotives together and still under the control of one operator. It is a question, however, whether the strength of the draft rigging will ever permit coupling two of these large electric locomotives together at the head end of the train, in as much as the starting effort of one locomotive is 120,000 lb. and the 240,000 lb. starting effort of two locomotives would undoubtedly prove too much for any draft rigging now in use.

The trolley construction used upon the Butte, Anaconda & Pacific Railway comprises a steel catenary from which is hung, by means of loop hangers, a 4 0 copper trolley wire operating at 2,400 volts direct current. The loop hanger permits this trolley wire to ride up and down under pressure of the current collector and independently of its catenary support, and this provides a very flexible form of construction. The result has been that the 5 in. steel tube rollers used to collect the current on the Butte, Anaconda & Pacific have given a life of nearly 30,000 miles when operating in passenger service where the maximum speed approaches 50 miles per hour. The construction being installed upon the Chicago, Milwaukee & St. Paul Railway, is a development of that now in successful operation upon the Butte, Anaconda & Pacific Railway. It utilizes the 4 0 steel catenary and the loop hanger, but provides for two 4 0 trolley wires located side by side and alternately suspended from the same steel catenary. This alternate suspension of the twin trolley conductors provides for extreme flexibility of the overhead conductor, as when the current collector passes beneath the clip of one strap hanger the other trolley wire is hanging free and there is absolutely no tendency to spark, as is the case with the single conductor. Tests made at the Schenectady and Erie Works of the General Electric Company show that 2,000 amperes can be successfully collected at 60 miles per hour and as this corresponds to 6,000 kw. at 3,000 volts, it is considerably in excess of the requirements of one locomotive collector.

The statement can be safely made therefore, that the high-voltage direct-current locomotive can be designed to meet the requirements of the heaviest class of main line service both as regards the capacity of its motors and ability to collect the required amount of current from the overhead trolley wires at any speed called for in passenger or freight service.

LOCOMOTIVE SUPERHEATERS

BY R. M. OSTERMANN, CHICAGO

Member of the Society

THE influence of superheating upon the design and operation of railroad locomotives is quite revolutionary, and much more unusual than upon stationary power plants. The keynote of locomotive design and operation has always been simplicity, and railroad men have maintained an attitude of conservatism well founded upon their experience in operating numerous individual power plants with a high degree of precision and often under conditions adverse to the proper maintenance of any kind of machinery. However, that there are to-day in operation about 32,000 locomotives equipped with just one design of superheater, nearly 12,000 of which are being used on the railroads of this continent, and that a very large percentage of the locomotives being ordered at this time are to be equipped with the device, is a proof that the benefits of superheating are appreciated.

In locomotives, the particular value of an improvement in cylinder performance, or, in other words, of a reduction of weight of steam used per indicated horse power hour, is to be found in the limitations of weight and clearance imposed upon the boiler, limitations which have been felt more and more as the demand for horse power capacity increased.

In proportioning his engines and boilers so as to furnish a given amount of sustained power, the stationary plant designer has no serious difficulties if he can obtain sufficient boiler room space and substantial foundations. His problem resolves itself into choosing, among the known improvements, a combination that will produce the required horse power with a minimum of coal and a maximum assurance of uninterrupted service.

The problem of the locomotive engineer is fundamentally different. He must obtain a certain sustained power from a boiler limited in weight to what is required for adhesion and in bulk by what road clearance and track curves allow.

The desire to increase the operating efficiency of existing track, the inability of the railroads to reduce grades in pace with the development of the traffic in many cases and the recent introduction of all-steel and steel underframe cars, are factors that are responsible for the rapid growth of weight and power of locomotives in this country. The average weight has been increasing rapidly. The boiler barrels of locomotives have reached their practical limit in diameter, and their length has also greatly increased with the increase in the number of driving axles to safely take care of the larger adhesion weights corresponding to the increased cylinder power.

A comparison of heating surfaces in stationary and locomotive boilers is very instructive. While in stationary boilers a square foot of heating surface is provided for evaporating from 4 to 7 lb. of water per hour, locomotive boilers have to evaporate as much as 20 lb. or more per sq. ft. of heating surface. Some recent Pennsylvania tests indicated evaporations of 23.3 lb. per sq. ft. of heating surface under forced conditions and with coal fuel.

In view of such extraordinary figures, illustrating better than any arguments could the limitations of steam generating

in locomotive operation, any device that would reduce the pounds of steam per indicated horse power hour and at the same time could be applied without materially impairing the boiler efficiency or greatly increasing the weight of the locomotive, two important considerations, would afford material relief; and a correctly designed locomotive superheater is such a device.

The prevailing type of locomotive superheater is shown in Fig. 1 and a unit in detail in Fig. 2. More than 11,000 superheaters of this design are now in use in this country. This superheater is of the fire-tube or, more generally speaking, of the parallel-flow type, in distinction to the smoke-box superheater which operates on the series principle or, in other words, utilizes the heat of the gases left after their contact with the evaporating surface.

Fig. 3 is a curve showing a general relation between coal consumption per indicated horse power hour and superheat,

in a more intense action of the superheater in decreasing the specific steam consumption of the locomotive.

The saturated steam locomotive boiler does not possess any boosting feature. On the contrary, the moisture in the steam fast increases, making the saturated locomotive fail when forced.

The benefit of the superheater in boosting the steam temperature and power of the locomotive probably finds its limit at the point where too great an increase of cut-off halts a further reduction of specific steam consumption. Just at what speed and power this takes place depends upon the proportions of the boiler, as compared with the cylinders and wheels; and the problem of the designer is to provide a boiler with proper proportions of evaporating and superheater heating surface so that the largest possible amount of sustained horse power can be had at the speed at which the engine is required to operate normally.

FIG. 1 DETAILS OF THE PREVAILING TYPE OF LOCOMOTIVE SUPERHEATER

as experimentally established by Dr. W. F. M. Goss, to whom we are greatly indebted for a thorough investigation of the

benefit of superheating carried out on a locomotive at the Purdue testing plant. The curve is interesting in so far as it clearly shows the larger proportionate economies with increase in steam temperature.

The Pennsylvania Railroad has also carried out extensive tests at its Altoona testing plant, and the bulletins issued by this company giving the results of these tests are recommended to all who wish to make a detailed study of locomotive fire-tube superheaters. The tests fully confirm the claims made by the designers of this type of superheater, and show the following fundamental relations:

The superheat increases at a nearly constant rate with the indicated horse power of the locomotive. It also varies in a generally similar manner with the draft and the rate of evaporation, both of which are automatically regulated to suit the load of the locomotive through the agency of its exhaust. The superheater is, therefore, an effective power booster for the locomotive, and this is a very valuable feature from an operating standpoint. An increase in the steam demand upon the boiler necessitates the evaporation of more water per square foot of evaporating surface, which latter results

A comparison of indicator cards taken from saturated steam and equally-sized superheated steam locomotives for either equal power output or equal steam consumption or water rate is most impressive. This comparison can be found in the above-mentioned Pennsylvania reports. In a locomotive, the area of the indicator card is indicative of haulage capacity. The greater the area of the card at a certain speed, the more tons can be hauled on the drawbar, and the greater the earning capacity of the locomotive. The addition of a correctly-designed superheater makes it possible to increase greatly the area of the card at a certain speed, and therefore to increase the haulage and earning capacity beyond that of a saturated steam locomotive by increasing the cut-off or by "dropping her down," and still retain the balance between steam generation and consumption.

Savings in coal and water per unit of power developed, such as shown by the tests, are now being obtained in everyday operation. As a rough average, a coal saving of 25 per cent and a corresponding water saving of 35 per cent, while the engine is performing useful work, can be expected, and thermally accounted for, with the knowledge we have of the average amount of cylinder condensation which takes place in saturated steam locomotives.

THE WASHBURN SHOPS OF THE WORCESTER POLYTECHNIC INSTITUTE

BY GEO. I. ALDEN, WORCESTER, MASS.

Member of the Society

THE germ thought to which the Washburn Shops trace their origin doubtless existed first in the mind of Ichabod Washburn, the founder of the Washburn and Moen branch of the American Steel & Wire Company, at present a branch of the U. S. Steel Corporation. The first paragraph in Mr. Washburn's letter of gift to the Trustees of the Institute reveals the blending of purely practical, with high moral and ethical, ideals. He says:

"I have long been satisfied that a course of instruction might be adopted in the education of apprentices to mechanical employments, whereby moral and intellectual training might be united with the processes by which the arts of mechanism, as well as skill in the use and adaptation of tools and machinery are taught, so as to elevate our mechanics as a class in the scale of intelligence and influence, and add to their personal independence and happiness, while it renders them better and more useful citizens, and so more like our Divine Master, whose youth combined the conversations of the learned with the duties of a mechanic's son, and whose ideas and teachings now underlie the civilization of the world."

It was long before this letter was written that Mr. Washburn had conceived the idea of a school for apprentices. He had conferred with Rev. Seth Sweetser, D.D., about his plans, but during the Civil War the project "slumbered." Before the consideration of this plan of Mr. Washburn's was revived, John Boynton of Templeton, Mass., had offered \$100,000 to endow a school to be located in Worcester. Mr. Boynton's gift was accepted, and a corporation was formed fifty years ago. Trustees were chosen, who made plans for the new school which were such as to include Mr. Washburn's ideas. Mr. Washburn finally very heartily consented to build and endow the Washburn Shops as a department of the Worcester County Free Institute of Industrial Science, now designated more briefly as the Worcester Polytechnic Institute. In doing this, he relied upon the other departments of the Institute to do the purely academic work required in the instruction of the apprentices.

In his letter of gift, Mr. Washburn provided for the appointment of a superintendent of the shops, specifying quite fully his duties. He recognized that the plan was an experiment, and stipulated that in case the trustees felt that the plan proposed could not be successfully and advantageously carried out, that it might be abandoned and the funds given for the support of the shop might be used for the benefit of the "main design of the Institute," mentioning the department of Mechanical Engineering in that connection, and stipulating that in such case a part of the income of the funds should be given to needy and deserving students to aid them in pursuing their education.

The purpose of the establishment of the Shops, as it ex-

isted in the minds of Mr. Washburn and the original trustees of the Institute, was to combine more closely theory and practice in the teaching of engineers. Mr. Washburn desired and enjoined that the apprentices should have instruction in the school in those branches of science that had a bearing upon their problems and work in the shop. The trustees intended that, by means of the shop practice, the students should be taught how to make their knowledge of science valuable to the industries of the County; that they should combine skill in the methods and practices of the mechanic arts with adequate knowledge, intelligence and understanding of the sciences underlying these processes.

The first notable achievement of the Shops is their continued existence and usefulness, although the establishment of the Shops as a part or department of the Institute was clearly recognized by the founder and original trustees as an experiment. Indeed, the lines upon which the Institute itself was planned were, for those times, so original, and such a departure from recognized types of education, that the trustees declared their unwillingness to put in charge of the Institute, either as President or the heads of the leading departments, any of the experienced and successful educators of that time; for they realized that the traditions of the established educational routine had such a hold upon the men who had espoused the cause of education, that any plan which included any radical departure from methods then existing would have little chance of success under the direction of the trained and experienced educators of that day.

If there were some who acquiesced in the value of technical training, there were apparently none who could tolerate instruction in a commercial shop or could see any connection between commercialism and education. They felt that there could not have been anything learned in making a product that was afterward sold. The aim, however, in making the goods in a commercial shop was not primarily to sell them, but to have them made by correct methods and up to commercial standards. They would be fit for the market, and, being fit, would likely be sold. The fact that the student knew that the goods he helped to make were standard, and not destined to find their way immediately to the scrap heap, had a fine influence upon the mind and the work of the students.

The second achievement is that the Shops have proved that it is possible and practicable for commercial shops devoted to instruction to be largely or entirely self supporting. The record shows that there have been periods in the history of the Shops during which even a considerable balance of profit has been shown. This condition requires more than simply manufacturing goods that go into the market; it means the highest order of business management and that the shop must have a business. It means that the students may learn in such a shop not simply the correct mechanical processes, but how to produce at a profit and that an opportunity is given the student for instruction and practice in

Presented at a meeting of the Worcester local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on June 8, 1915, in connection with the Celebration of the 50th Anniversary of Worcester Polytechnic Institute.

shop administration and management coincidentally with the period of his scientific and cultural studies.

A third achievement is that the Washburn Shops, by their plan and practice, have established the fact that the only place in which to teach successfully the application of science to the mechanical industries is the commercial shop. Every argument used in the years around 1870 in support of the plan of Mr. Ichabod Washburn and the trustees of the Institute is used today by the advocates of practical training for engineers.

The fourth achievement of the shops by which they must be mainly judged as an educational force is their benefit to the students who have been trained in the shops. The persistence of the shops through a long period of opposition; their financial record; their sound principles; all these are not to be regarded as ends in themselves, but only as the means to the attainment of a much higher aim, viz.—a better

by President Ira N. Hollis, of the Worcester Polytechnic Institute, to refer to his article entitled "Technical Education for the Professions of Applied Science," to be published by the Engineering Congress of the Panama Exposition. He compares the course in mechanical engineering in the Massachusetts Institute of Technology, the University of Michigan, and the Worcester Polytechnic Institute by giving the total hours in all subjects, including preparation. The studies in each school are divided into seven main groups, as follows:

- Group 1 —Language, History and Economics
- " 2 —Pure Science
- " 3a—General Applications of Science
- " 3b—Special Applications of Science
- " 4 —Drafting and Designing
- " 5 —Field and Laboratory
- " 6 —Summer Work
- " 7 —Physical and Military

The total hours in each group and for each of the schools mentioned, are approximately as follows:

	Wor. Poly.	Mass. Inst.	Univ. of Mich.
Group 1	1300 hr.	850 hr.	1200 hr.
" 2	1750 "	1550 "	1500 "
" 3a	1100 "	1250 "	900 "
" 3b	900 "	925 "	1950 "
" 4	550 "	550 "	250 "
" 5	1250 "	625 "	650 "
" 6	500 "	300 "
" 7	100 "
	7350 "	5850 "	6750 "

FIG. 1. CHART SHOWING DISTRIBUTION OF HOURS IN MECHANICAL ENGINEERING AT WORCESTER POLYTECHNIC INSTITUTE

type of education for young men pursuing the study of mechanical or allied branches of engineering. The shop courses, covering operations in cabinet work, in pattern making, moulding, core-making, smelting, and all foundry processes, forging, blacksmithing, machine shop practice, machine design, selection of suitable material of construction, care of tools, familiarity with the materials for water and steam piping, care and operation of steam boilers, steam and other engines, handling of repair jobs, experience with cost systems, accounting, efficiency methods, as applied to the organization of business and the production of manufactured products; all these and other kindred features have, by general consent, resulted in great benefit to the more than 700 students who have graduated from the Department of Mechanical Engineering at the Institute, not to mention those who had shop training in connection with their course in Electrical Engineering.

The shop instruction and practice, however, have never taken the place, or reduced the amount of, instruction in the theoretical studies and in laboratory work, either in range or quantity below that of other first rank technical schools. In illustration and proof of this statement, I am permitted

FIG. 2. CHART SHOWING DISTRIBUTION OF HOURS IN MECHANICAL ENGINEERING AT MASSACHUSETTS INSTITUTE OF TECHNOLOGY

The advantages resulting from a course such as this are many. The fundamental conditions for the type of instruction illustrated by the Washburn Shops are, as we have seen, commercial shops, and the distribution of shop practice throughout the entire engineering course. The first of these conditions secures a degree of shop experience as broad as the shop business permits. The second gives opportunity to bring the theory of the academic work into close and continuous relation to the shop practice. The consideration of the advantages of the commercial shops involves the question of the value and advantage to the young engineer of

shop experience. The manufacturing shops of the country are the connecting link between theory, invention, design, on the one hand, and shop production on the other hand. It is in the shops that theories are modified and perfected, that inventions are made to materialize and become useful, that designs are corrected to conform to the necessities of possible and economical production. The shops stand in a relation to the technical schools of the country similar to that of hospitals to schools of medicine and surgery. Surgeons cannot be produced without hospital practice and experience. The engineer needs to have had shop practice for the same reason that the surgeon needs to have had hospital practice and experience.

That the engineering student should get advantages from experience in connection with so indispensable an agency for the carrying out of all engineering enterprises seems hardly to need emphasis. It may, however, be pertinent to mention specifically some of these advantages:

FIG. 3. CHART SHOWING DISTRIBUTION OF HOURS IN MECHANICAL ENGINEERING AT UNIVERSITY OF MICHIGAN

First. The possession of mechanical skill has a value which is sometimes much underestimated. It gives one confidence in himself as an independent producer of something worth while—of something which has pecuniary value to him. It gives the young engineer a much better start and insures him a more rapid advancement in his profession. It enables one to direct mechanical operations with confidence and success, and thus gives the young graduate an entrance to one of the most important and promising fields for advancement, viz., the directing and management of skilled men. This is of particular value to men who hope to have a manufacturing business of their own.

Second. Shop experience helps one to get an early start in his profession. The most common question, and often the most pathetic as well, which confronts the graduate is, not what do you know, but what can you do? The man with shop experience of the kind under present consideration can say to the employer, in answer to this question, I can make patterns; have done some work in a commercial foundry; can operate ordinary machine tools; can install a system of keeping costs of production; make working drawings for use in an up to date shop; and if you are likely to have any

employment in other lines of engineering work for which my education has also fitted me, I would be glad to start at almost any practical work that offers. To be able, in consequence of shop experience, to make such an answer, may be, and very often is, the key that opens a door of wide opportunity.

Third. The economy of time which is secured by gaining shop experience from weekly practice in a commercial shop, during the whole period of technical training, is an advantage to the engineering student. The graduate who has had this shop experience may have saved a year or two of time in getting established in his profession or business.

The advantages already mentioned of shop experience are those that mainly accrue to the individual student or graduate. We turn now to a broader subject, the design and standardization of machines or structures and their parts, including the necessary jigs, tools, and accessories. It is in these matters that the engineers, who have risen to high positions without mastering the shop regime, are costing the country and the world vast sums of money by compelling manufacturers to make mechanisms in impractical and expensive ways; by failing to incorporate in their designs and drawings standard bolts, screws, nuts, gears, and many other parts that can be purchased for a fraction of what a small lot can be made for; by neglecting to consider and adopt a design for a casting that can be readily handled in the foundry; by introducing fanciful curves and other forms, which add nothing to the value or beauty of the product, but only greatly to its shop cost. The man with the shop training thinks naturally and inevitably of these things. The man who has had no shop experience, unless he be by nature a prodigy in production, thinks less about these matters, and has not the experience to think effectively.

Also, the designing and constructing of material products involves the maintenance of a business organization. Operation of such an organization has become more complex and more important with the prevalence of large business enterprises. The engineer or manufacturer should understand the functions of each department of the business organization which he serves. The commercial shop offers facilities for acquainting the engineering student with the modern methods of business management and business efficiency by giving him practice in the different departments of the business organization, including time keeping, systems of cost accounting, sales management, bookkeeping, store keeping, draughting room practice, cost estimating, and methods of introduction of efficiency systems; in all these and other allied subjects the commercial shop can offer practice valuable and almost indispensable to an engineer who would master his profession and be able to conduct his practice in harmony with and to the advantage of the whole organism of which he happens to be a part.

Schools for teaching the sciences that underlie the industries were founded in this country at dates preceding the founding of the Worcester Polytechnic Institute, as, for example, the Rensselaer Polytechnic Institute in 1824, and the Lawrence Scientific School in 1847. Hon. Samuel A. Eliot was an able advocate of the plan of offering more advanced scientific courses at Harvard; and, while he was treasurer of Harvard College, the governing boards of Harvard University approved a plan for the establishment of an advanced school of science and literature to be called the Scientific

School of the University at Cambridge; in recognition of the gift by Abbott Lawrence of \$50,000, the overseers designated the new school as The Lawrence Scientific School in the University at Cambridge. These schools, and others founded later, all provided for instruction in the sciences that were considered practical, in the sense that a knowledge of these branches of science was necessary to the development of the great engineering, mining, transportation, and other industries.

The result of the training of these schools was a body of educated scientists and engineers. The carrying out of their ideas required a great body of skilled workmen. These workmen were trained by being apprenticed to the various trades. The educated scientists had usually no skill or knowledge of practical, mechanical or construction processes. There was, and to a large extent is today, a broad gap, so far as instruction is concerned, between the trained scientist and the skilled mechanic. This gap has been somewhat narrowed in more recent times by the introduction of laboratories equipped with modern engineering apparatus. But, so far as the training in most scientific or technical schools is concerned, there is still a wide space not yet covered by any well defined system of instruction. In this space have grown up partial and inadequate systems, such as manual training schools, trade schools that do not teach trades, and various independent schools, outlined and directed by almost every grade of talent and attainment except commercial, trade and business experience. But the plan outlined nearly fifty years ago for the Worcester Polytechnic Institute provided for instruction both in the sciences which underlie the industries of the country and their application to the processes and work of the Shops. The plan was harmonious and covered the whole ground. It brought theory and practice together in a direct and simple way. Along with mathematics, pure science and language, the student also would learn the equally important and disciplinary lessons of mechanical skill. While pursuing his engineering studies he would practice production of correct gears, difficult mechanisms, standard machines, prime movers, etc., etc. The adoption of this method of instruction involves connection of some kind with commercial shops; and Mr. Washburn provided for the Worcester Institute this necessary part of the equipment in the establishment and endowment of the Washburn Shops.

The Worcester Polytechnic Institute also has engineering and laboratory courses. It has, as shown in Dr. Hollis' paper, from which we have quoted, all the groups of studies found in engineering schools. It gives more time to instruction and preparation, to both the preparatory and the engineering studies, than the other typical engineering schools with which comparisons are made. It also has shop instruction and practice added, or as a surplus in the account. This showing ought to correct the misinformed and neutralize the false logic of the unthinking.

The training at the Washburn Shops has been improved and expanded from time to time during the past forty-six years to meet new conditions in business management and manufacturing and educational methods. These unique commercial shops, therefore, now enable the Worcester Polytechnic Institute to offer exceptional advantages to the student in mechanical engineering, the course in which they round out and complete.

NEW BUILDINGS OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY

THE local meeting of the Society in Boston, held March 31, 1915, was devoted to the Engineering Equipment of the New Technology Buildings. An illustrated talk was given by Harry Gay, equipment engineer in charge of the work for Stone & Webster Engineering Corporation, and following this Geo. E. Libbey of the firm of Hollis French & Allen Hubbard addressed the meeting. A. L. Williston, president of Wentworth Institute, concluded the meeting with an illustrated talk on the Lay-out of Educational Institutions. References to the remarks of the first two speakers follow.

Mr. Harry Gay described in detail, with the aid of numerous lantern slides, the general plan of the new buildings for the Massachusetts Institute of Technology, now under construction, as well as those contemplated, and discussed the proposed equipment of the engineering buildings and science laboratories. He stated that the water supply system received special consideration on account of the large demand of the hydraulic laboratories. The power station will supply alternating current at 2,300 volts, 60 cycles, to a substation for the electrical engineering department where, by means of special transforming and regenerating equipment of 500 k.w. capacity, currents up to 6,000 amperes and voltages up to 100,000 will be available for experimental purposes.

The group of science laboratories, situated apart from the engineering laboratories, will be most complete in their facilities for precise research work in addition to undergraduate instruction. The engineering buildings will also contain extensive hydraulic, steam and chemical laboratories in addition to the electrical department.

George E. Libbey described the heating, ventilating and plumbing arrangements of the buildings. There are three distinct systems of drainage, the sanitary, the rain water, and the underground. The last is for the purpose of keeping the surface water away from the buildings, insuring dry basements. In the plumbing system, continuous venting is employed, a new practice which is rapidly coming into use, as it requires less pipe and is less liable to stoppages. Forced hot water circulation was considered very carefully for this purpose, but a number of conditions governing the installation favored steam, and these were outlined in detail. Among these were the difficulties experienced in obtaining underground tunnels for suitable piping connections.

The heating and ventilating of the group of buildings presented many difficulties on account of the large amount of apparatus in the buildings. A vacuum steam system of heating was decided upon, with which, by means of thermostats operating automatically controlled valves, the temperature can be regulated within two degrees. In connection with the ventilating, supply fans in the basement take air from the windows and apply it to the interior. It is then collected in ducts and exhausted by discharge fans on the roof. The air for ventilation is tempered by primary heaters automatically controlled by thermostats. In the chemical building, the air is changed eight times an hour, and the fumes from the chemical hoods are abstracted through ducts by a special system of fans on the roof. In all, over 100 large fans, requiring 280 k.w., are installed.

TECHNICAL DISCUSSION

A RATIONAL BASIS OF COMPARISON OF THE DUTIES OF ELECTRICAL ELEVATORS AND HOISTING ENGINES

BY ANDREW M. COYLE, NEW YORK

Member of the Society

THE following brief discussion is intended to make clear the mechanical and electrical conditions which enter into and limit the efficiencies of the several types of electrical elevators and hoists now on the market. In view of the recent discussion of this subject at a local meeting of the Society and the apparent lack of a basis of comparison of these machines, it is hoped that the data here given and the simple algebraic formulæ, developed some years ago and recently revised, may furnish a working basis upon which the theoretic efficiencies of the several types of machines, and the several systems of *rigging* or methods of installation, may be compared and the power requirements for any given installation definitely computed.

In general, the engines in use fall into three classes: *a*, worm-gearred; *b*, spur-gearred, and *c*, direct-driven machines. The worm-gearred is the most common form of engine for elevator service, and the spur-gearred the most common form for general hoisting purposes. The helical or herring-bone gear is a special form of spur gear, and may be treated as such. The traction elevator is a special form of rope drive, and may be so treated regardless of whether the traction sheave is driven by means of gears or by a directly-attached motor. For convenience of reference, diagrams are given which show the arrangements of rigging most commonly used with electric elevator and hoisting engines.

EFFICIENCY

As it is desirable to compare the efficiencies of the several types of machine and several methods of installation, it will be convenient to make a general summary of the elements which enter into the problem. An electrical elevator or hoisting installation consists of: 1. A motor; 2. A system of electrical switches and resistances by which the motor is controlled; 3. A drum or sheave driven by the motor, either directly or by means of gearing; 4. A cable transmission to which is attached a car, and usually a counterweight; 5. A brake pulley and brake usually located on the motor shaft; and 6. Certain governing and safety devices which, though of great importance, do not affect the efficiency of the installation. It is quite obvious that electrical engines used for general hoisting purposes will come under the same mechanical laws, and may be treated by the same formulæ as are applicable to elevator machines.

The actual efficiency of an elevator can hardly be expressed by a percentage. The conditions under which they operate are extremely variable. The total current consumed by a machine per car mile when performing a specific duty is the only proper basis of comparison.

Economy demands that a machine must use current most efficiently when performing the duty for which it is most frequently used. From this it follows that the machine must be designed with reference to this duty. It follows also that, in cases where the loads to be lifted vary between wide lim-

its, a motor must be selected which will give a fair percentage of efficiency under the varying conditions. Commercial motors which are designed for continuous duty are rarely suitable for elevator service. The attempt to use such motors has led to the installation of a great number of inefficient, costly and unsatisfactory elevators.

It will be convenient to develop a few simple formulæ which may be applied generally to determine the quantity of current which should be required to perform any given duty with a machine of any one of the standard types.

The energy developed in the motor is used *first*, to impart motion to the system, and *second*, to lift the unbalanced load in the car. As we develop high car speeds, the proportion of current used to produce acceleration increases until a point is reached at which it is not practicable to bring the car to full speed between floors. This limits the speed of elevators for local service.

The masses to which motion must be imparted are the car, counterweight, load, etc., which move in straight lines, and the drum sheaves, armature, etc., which rotate about their centers. In computing the inertia of a rotating body, we consider its mass as concentrated at the *radius of gyration*. The radius of gyration may be expressed as a fraction of the actual radius, or as a fraction of the distance from the center to some known point which bears a fixed relation to the actual radius.

The radii of gyration of the armature and brake-pulley may be expressed as fractions of their actual radii, but the radii of gyration of the sheaves and of the drum may be more conveniently expressed as fractions of the distance from the shaft center to the cable center. The patterns of sheaves and drums in common use are quite similar. It will be near enough for practical purposes if we use in our formulæ the radii of gyration which have been calculated for a sheave and drum of standard design. If in the case of any particular machine the patterns differ radically from those in common use, other values may be calculated. In Table 1, *r* is used to indicate the radius of gyration which is to be considered as the ratio between the center of gyration and the measurement to which it is referred.

TABLE 1 RADIUS OF GYRATION OF REVOLVING PARTS

When several parts are assembled on one shaft the center of inertia has been computed for the combined masses

Name of Part	<i>r</i>	<i>r</i> ²
Sheave carrying two or more ropes	0.922	0.83
Winding drum with attached drum neck, gear center and gear	0.80	0.64
Traction sheave with heavy hub and spokes	0.80	0.64
Brake-pulley with solid web and flange coupling	0.707	0.5
Armature and shaft	0.707	0.5

SYMBOLS USED IN ANALYSIS

- m = Mass in pounds of the car, counterweights, cables, counterbalance chains and attachments, plus the entire live load. (All these parts move with the same speed.)
- m_1 = Mass in pounds of all sheaves (excepting the driving sheave in the case of traction machines).
- m_2 = Mass in pounds of drum (or traction sheave), drum neck, gear center and gear.
- m_3 = Mass in pounds of brake pulley and flange coupling (if coupling is used).
- m_4 = Mass in pounds of armature and shaft.
- m_5 = Mass in pounds of intermediate gear, in case of machines having double gear reduction.
- m_6 = Mass in pounds of cables in motion, in case of machine having 2:1 rigging.
- M = The Mass Aggregate; that is, a mass equivalent to the aggregate of all the masses in the system multiplied by the factors which modify their effective values in the total inertia of the system.
- M_1 = Negative Mass Aggregate.
- v = Velocity of the car, in feet per second.
- $v_1, v_2, v_3, v_4, v_5, v_6$, etc. = Velocities of the centers of gyration of the masses having the corresponding subnumbers.
- D = Diameter of winding drum or traction sheave, in feet, center to center of cables.
- d_3 = Diameter of brake-pulley, in feet.
- d_4 = Diameter of armature, in feet.
- d_5 = Diameter of intermediate gear, in feet (used in case of machine having double gear reduction).
- L = Unbalanced load, in pounds.
- F = Foot pounds energy which must be developed by the motor during the period of acceleration to impart the required velocities to the different parts of the system and to lift the unbalanced load.
- F_1 = Foot pounds energy necessary to impart the velocities $v_1, v_2, v_3, v_4, v_5, v_6$, etc., to the masses of the system.
- F_2 = Foot pounds energy necessary to lift the unbalanced load during the period of acceleration.
- F_3 = Foot pounds energy necessary to overcome friction during the period of acceleration.
- F' = Foot pounds energy available to drive the motor during the period of retardation.
- T = Average torque required of motor during the period of acceleration expressed in pounds at one foot radius.
- T_1 = Torque required of motor when running at normal speed, expressed in pounds at one foot radius.
- r_1, r_2, r_3, r_4, r_5 , etc. = Ratios which the radii of gyration of the masses having the corresponding subnumbers bear to the measurements to which they are referred (see Fig. 1).
- t = Time in seconds allowed for acceleration from rest to full car speed.
- R = Gear ratio = Number of turns of armature to one turn of drum.
- R_2 = Ratio of intermediate gear (used in case of machines having double gear reduction).
- P = Percentage of efficiency of rope drive, including an allowance for friction of sheaves, benches and hatchway resistance.
- P_1 = Percentage of efficiency of gearing.
- P_2 = Percentage of efficiency of the intermediate gears (used in case of machine having double gear reduction).
- n = Number of turns of armature during the period of acceleration.
- h = Height load is lifted during the period of acceleration, in feet.
- g = Gravity = 32.18.

STARTING CONDITIONS

Using the symbols defined, we may establish certain relations between the values which they represent.

$$F = F_1 + F_2 + F_3 \dots [1]$$

$$F = 2\pi nT \dots [2]$$

Since T is the average torque during the period of acceleration and the distance through which the torque acts is $2\pi n$, the above relation is obvious.

$$F_1 = \frac{mv^2 + m_1v_1^2 + m_2v_2^2 + m_3v_3^2 + m_4v_4^2}{2g} \dots [3]$$

The values of v_1, v_2, v_3, v_4 may all be referred to v taken as a unit. The radii of gyration of the drum and sheaves are referred to the distance from shaft center to cable center for the reason that the cable center moves with the velocity v . Without considering the diameters of the drum and sheaves, we have:

$$v_1 = vR_1 \quad v_2 = vR_2 \quad \text{hence } v_1^2 = v^2R_1^2 \quad v_2^2 = v^2R_2^2$$

In the case of the brake-pulley and armature we must consider the gear ratio and the diameter.

$$v_3 = v \frac{d_1R_1}{D} \quad v_4 = v \frac{d_4R_4}{D} \quad \text{hence } v_3^2 = \frac{v^2d_1^2R_1^2}{D^2} \quad v_4^2 = \frac{v^2d_4^2R_4^2}{D^2}$$

Substituting these values in equation [3] we have—

$$F_1 = \frac{v^2}{2g} \left((m + m_1R_1^2 + m_2R_2^2 + (m d_1^2 R_1^2 + m_4 d_4^2 R_4^2) \frac{R^2}{D^2}) \right) [4]$$

In finding the value of F_2 , it may be noted: *first*: The power required to impart motion to the armature and brake-pulley is not affected by the efficiency of the machine; *second*: The power required to impart motion to the drum and gear is affected by the efficiency of the gear, expressed by the percentage P_1 ; and *third*: The power required to impart motion to the sheaves, car, counterweight, cables, chains, etc., is affected both by the efficiency of the gear and by the efficiency of the cable transmission P . This condition may be expressed:

$$F_2 + F_3 = \frac{v^2}{2g} \left(\frac{m + m_1R_1^2}{P \times P_1} + \frac{m_2R_2^2}{P_1} + \frac{(m d_1^2 R_1^2 + m_4 d_4^2 R_4^2) R^2}{D^2} \right) [5]$$

The quantity in the parenthesis in equation [5] is the mass aggregate expressed by the symbol M . It is the total inertia of the system, including friction, which in this case acts to all intents as an increase of mass.

It is obvious that

$$F_1 = L \times h \dots [6]$$

By the laws of acceleration

$$h = \frac{1}{2} vt \dots [7]$$

Hence

$$F_1 = \frac{1}{2} Lvt \dots [8]$$

The number of turns made by the drum during the period of acceleration will be $n \div R$. The circumference of the drum is πD ; hence we have

$$h = \frac{\pi Dn}{R} \dots [9]$$

From equations [7] and [9] we have

$$2\pi n = \frac{Rvt}{D} \dots [10]$$

For running conditions, only the friction of the parts and the work of lifting the load are to be considered.

The above considerations lead to the following mechanical formulae:

Energy required for acceleration

$$F = \frac{1}{2} \left(\frac{Mv^2}{g} + Lvt \right) \dots [11]$$

Average torque required during period of acceleration

$$T = \frac{L}{2R} \left(\frac{Mv}{gt} + L \right) \dots [12]$$

Velocity which may be imparted in a given time by a given average torque

$$v = \frac{gt(2RT - L)}{M \left(\frac{D}{R} - L \right)} \dots [13]$$

Time required to produce a given velocity by means of a motor having a given torque

$$t = \frac{Mv}{g} \left(\frac{D}{2RT} + \frac{1}{L} \right) \dots [14]$$

Torque required for running

$$T_1 = \frac{D}{2RP_1} \left((1 - P)(m + m_1 + m_2) + L \right) \dots [15]$$

which holds until the value in the parenthesis becomes zero. When the quantity assumes a negative value use

$$T_1 = \frac{DP_1}{2R} \left(L - (1 - P)(m + m_1 + m_2) \right) \dots [15a]$$

In selecting a motor to develop torque necessary to produce acceleration it must be noted that the average torque is not simply a mean between the highest and lowest torque developed during the period of acceleration. The average torque developed by the motor must meet the conditions $T = \frac{F}{2\pi n}$ in which n is the number of revolutions made by the armature during the period of acceleration.

Equation [15] represents the running conditions of geared machines in general. In the case of the direct driven traction machines $R =$ unity and P_1 takes into account only the friction of the armature bearings. In the case of the 2:1 rigging the value of R is 2.

The following formulae are derived from equation [5]:

FORMULAE FOR MASS AGGREGATE

A general formula for the mass aggregate of a machine having a single gear

$$M = \frac{m + m_1 r_1^2}{P P_1} + \frac{m_2 r_2^2}{P_1} + \frac{R^2}{D^2} (m_3 d_3^2 r_3^2 + m_4 d_4^2 r_4^2) \dots \dots [16]$$

in which r_1, r_2, r_3, r_4 are the fractions which express the ratios between the radii of gyration and the actual radii of the rotating parts. For convenience, these fractions have been calculated for the parts of a machine of standard design and the numerical values substituted in the general formula. Unless the machine under consideration is of unusual design these values are sufficiently accurate.

For machine with a single gear ratio, whether worm or spur gear

$$M = \frac{m + .85m_1}{P P_1} + \frac{.64m_2}{P_1} + \frac{R^2}{2D^2} (m_3 d_3^2 + m_4 d_4^2) \dots [17]$$

For machine having a double gear ratio, either worm or spur gears

$$M = \frac{m + .85m_1}{P P_1 P_2} + \frac{.64m_2}{P_1 P_2} + \frac{R^2}{2D^2} (m_3 d_3^2 + m_4 d_4^2) \dots \dots \dots [18]$$

For direct driven machine, either winding drum or traction

$$M = \frac{m + .85m_1}{P P_1} + \frac{.64m_2}{P_1} + \frac{m_3 d_3^2 + m_4 d_4^2}{2D^2} \dots \dots \dots [19]$$

For geared machine with 2:1 rigging, either winding drum or traction

$$M = \frac{m + 3.4m_1 + 4m_2}{P P_1} + \frac{2.56m_2}{P_1} + \frac{2R^2}{D^2} (m_3 d_3^2 + m_4 d_4^2) [20]$$

For machine rigged 2:1 with direct motor drive

$$M = \frac{m + 3.4m_1 + 4m_2}{P P_1} + \frac{2.56m_2}{P_1} + \frac{2}{D^2} (m_3 d_3^2 + m_4 d_4^2) [21]$$

In formulae [5] and [6] the weight of the traveling sheaves should be included in both m and m_1 . m_0 = only the mass of cables in motion, not the standing part.

PERCENTAGES OF EFFICIENCY

The values of P, P_1 and P_2 are necessarily approximate. At the outset we must assume that the machines are properly constructed and properly lubricated. The duty performed in the cable transmission during the period of acceleration is much heavier than that performed under running conditions. In order to express P as a percentage of the load in motion we may use the formula $P = 1 - \left(\frac{aw}{m + m_1} + c \right)$, in

which W is the total load carried on all the sheaves and on the drum, a is the loss in one sheave expressed as a percentage of the load on the sheave and c is a constant introduced to provide for hatchway friction. The values of P in the diagrams are based on the values $a = 0.03$ and $c = 0.02$. This is a very liberal allowance for starting conditions. For running conditions the values $a = 0.015$ $c = 0.01$ may be used.

The efficiency of a worm gear may be determined by the formula $P_1 = 1 - (a \times \text{cosecant } \phi + b)$

in which ϕ is the pitch angle of the thread, a the coefficient of friction and b a constant added to provide for the power expended in the bearings and in churning the oil.

The efficiency of tandem or balanced worm gearing is not greater than that of a single worm and gear provided with a good ball-bearing thrust. For light loads, the single gear is preferable for the reason that there is less back lash and less difficulty in setting up the machine and in making repairs.

The efficiency of spur and herring bone gears varies from 0.985 in the case of the best cut gears properly lubricated

TABLE 2 VALUES OF P_1 FOR WORM GEAR WITH COEFFICIENT OF FRICTION OF 0.03

Deg.	P_1	Deg.	P_1	Deg.	P_1	Deg.	P_1	Deg.	P_1
8	0.734	11	0.793	14	0.826	17	0.847	20	0.862
9	0.758	12	0.806	15	0.834	18	0.853	21	0.866
10	0.777	13	0.817	16	0.841	19	0.858	22	0.870
								25	0.879

TABLE 3 VALUES OF P_1 FOR WORM GEARS WITH COEFFICIENT OF FRICTION OF 0.05

Deg.	P_1	Deg.	P_1	Deg.	P_1	Deg.	P_1	Deg.	P_1
8	0.590	11	0.688	14	0.743	17	0.779	20	0.804
9	0.630	12	0.709	15	0.757	18	0.788	21	0.812
10	0.662	13	0.728	16	0.769	19	0.796	22	0.817
								25	0.822

and provided with anti-friction bearings, to 0.93, which will be developed by any cut gears that are set up with a fair degree of accuracy and moderately lubricated.

Table 2 shows values of P_1 for worm gears of pitch angles from 8 to 25 deg., in which the coefficient of friction $a = 0.03$ and constant $b = 0.05$. This represents about the best attainable condition.

Table 3 shows values of P_1 for worm gears of pitch angles from 8 to 25 deg., in which the coefficient of friction $a = 0.05$, constant $b = 0.05$. This represents average practice.

The pitch line of the worm normally slides on the pitch line of the gear. The angles are determined on those lines. As a matter of fact the angle is variable, being greatest near the roots of the threads and less toward the periphery. Worm gears tend to wear more rapidly than herring bone gears. This wear increases the clearance and causes back lash when the load is reversed. This trouble is particularly noticeable in the case of tandem gears. In the case of the direct driven machine there is no gearing, and P_1 may be given a value of 0.99 which allows for the friction in the armature bearing.

Referring to the equations [16] to [20] it will be noted

that the mass aggregate is composed of two parts. The high speed component, consisting of the armature and attached parts, and the low speed component, which includes all other moving parts. In all geared machines the power required to impart velocity to the high speed parts is a considerable item. It is important therefore to so proportion these parts as to reduce their inertia as much as possible.

Since the gear ratio and the diameter of the armature both enter into the equation as squares, the natural suggestion is to reduce the gear ratio and the diameter of the armature. We cannot do both; a reduction of the gear ratio requires

lation of an elevator in a building in which the rise is 250 ft. We will assume that the car weighs 3000 lb., the counterweight 4200 lb., the chains and cables 3200 lb. and that the maximum load is 3000 lb. In this case, the counterweight is 1200 lb. heavier than the car and the maximum unbalanced load will therefore be 1800 lb. The value of m in the formula will be as follows:

For car *running empty*, $m = 10,400$ lb.

For car with *balanced load*, $m = 11,600$ lb.

For car with *full load*, $m = 13,400$ lb.

In a building of the height stated, it would be usual to

FIG. 1. DIAGRAMS OF THE FORMS OF RIGGING MOST COMMONLY USED SHOWING VARIATIONS IN PERCENTAGES OF ROPE DRIVE EFFICIENCY

an increase of torque, which cannot be obtained without an increase in the size and weight of the armature, so the two conditions to some extent balance each other.

Another consideration also tends to offset the gain of a low gear ratio. Owing to electrical conditions, we cannot decrease the surface speed of the armature without in a greater measure increasing its size and weight. Very slow speed motors are inefficient, difficult to control and do not readily meet the conditions of varying load.

For the purpose of illustration, let us consider the instal-

install a machine of the overhead traction type. We will, therefore, consider:

FIRST, A direct driven machine: diameter of armature, 32 in. and weight 5000 lb.; diameter of brake-pulley, 36 in. and weight 800 lb.; car speed, 500 ft. per min.; and time of acceleration, 3 seconds.

SECOND, Machine driven by herring-bone gear: diameter of armature, 20 in. and weight 1400 lb.; diameter of brake-pulley, 18 in. and weight 100 lb.; diameter of gear, 36 in. and weight 1000 lb.; gear ratio, 6:1; gear efficiency, 97 per

cent; car speed, 500 ft. per min.; and time of acceleration, 3 seconds.

THIRD. Machine driven by worm gear; diameter of armature, 15 in. and weight 800 lb.; diameter of brake-pulley, 18 in. and weight 100 lb.; diameter of gear, 30 in. and weight 800 lb.; car speed, 300 ft. per min.; time of acceleration, 4 seconds; gear ratio, 24:1; and gear efficiency, 0.86.

In each case we will use a traction sheave 36 in. in diameter, weighing 1000 lb., and an idler 32 in. in diameter, weighing 700 lb. It should be here noted that, in the cases of the geared machines, the diameter of the driving sheave and gear can be increased without increasing the size of the armature. In the case of the direct driven machine this is not possible. The use of a 42-in. sheave slightly increases traction and very greatly decreases the wear on the cables.

Using the weights and diameters above given in the formulae for mass aggregate, we obtain for the car running empty:

First.

$$M = \frac{10400 + 0.85 \times 700}{0.89 \times 0.99} + \frac{0.64 \times 1000}{0.99} + \frac{800 \times 3^2 + 5000 \left(\frac{3}{2}\right)^2}{2 \times 3^2}$$

= 12478 + 646 + 2375 = 15,499

Second.

$$M = \frac{10400 + 0.85 \times 700}{0.89 \times 0.97} + \frac{0.64 \times 2000}{0.97} + \left(\frac{100 \left(\frac{1}{2}\right)^2 + 1400 \left(\frac{2}{2}\right)^2}{2 \times 3^2} \right) 6^2$$

= 12736 + 1320 + 8228 = 22,283

Third.

$$M = \frac{10400 + 0.85 \times 700}{0.89 \times 0.86} + \frac{0.64 \times 1800}{0.86} + \left(\frac{100 \left(\frac{1}{2}\right)^2 + 800 \left(\frac{1}{2}\right)^2}{2 \times 3^2} \right) 24^2$$

= 14365 + 1340 + 47200 = 62,904

It is to be noted that the mass aggregate of the geared machine is much greater than that of the direct-driven machine, and that this is chiefly due to the inertia of the high-speed component. The mass aggregate for the balanced load and the full load, if calculated, will appear as in Table 4.

In the case of machine No. 1, the armature makes 53 r.p.m. and has a surface speed of 442 ft. per min.; this is a low speed for electrical efficiency and ease of control. In the case of No. 2, the armature makes 316 r.p.m. and has a

surface speed of 1663 ft. per min.; this is a good speed both for efficiency and control. In the case of No. 3, the armature makes 760 r.p.m. and has a surface speed of nearly 3000 ft. per min., which is not required for electrical efficiency or ease of control. There is no excuse for using this high speed motor excepting low first cost.

Having found values for F, T, T₁ corresponding to the specified values of r and t, we may proceed to the motor. If we are in possession of full data concerning the motors available for use, the formulae will show at a glance the most suitable motor. If no motor at hand will meet the condition, it will be necessary to change either the velocity or the time of acceleration.

It will be convenient to develop a few simple formulae which will give us an approximate estimate of electrical requirements. The following electrical symbols are assumed:

- Q = Energy in kw-hr. used per car mile in one direction for all purposes.
- q = Energy in kw-hr. used per car mile in making starts.
- q₁ = Energy in kw-hr. used by motor per car mile running at normal speed.
- q₂ = Energy in kw-hr. used by the motor per car mile exclusive of the distance traveled during the period of acceleration and retardation.
- q₃ = Energy in kw-hr. used per car mile during period of retardation.
- q₄ = Allowance made per car mile for current used in relay and brake magnets (watt-hr.).
- y = Energy lost in starting resistance during the period of acceleration (watt-hr.).
- y₁ = Energy lost in stopping resistance during the period of acceleration (watt-hr.).
- p = Percentage of efficiency of motor when operating under overload conditions to produce the torque T.
- p₁ = Percentage of efficiency of motor when operating under running conditions to produce the torque T₁.
- K = Mechanical equivalent of 1 kw-hr. = 2,654,200 ft.-lb.
- E = Line voltage.
- N = Number of starts made per car mile.

The items q₂, y and y₁ depend on the type of control used, and the extent to which the speed of the motor can be governed by field regulation. They are practically fixed quantities which enter into the equation each time the controller operates.

ELECTRICAL FORMULAE

The car makes N starts per car mile and at each start F ft.-lb. of energy are used. We also have to consider the electrical efficiency of the motor and the loss in the resistance:

$$i = \frac{FN}{Kp} + Ny, \dots \dots \dots [23]$$

The number of turns made by the armature per car mile is 5280R
πD—and at each turn the energy used is 2πT ft.-lb.

The running current per car mile will be

$$i_h = \frac{5280 \times 2RT}{DKp_1} = \frac{RT_1}{251Dp_1} \dots \dots \dots [24]$$

During each period of acceleration and retardation the car travels a distance approximately $\frac{1}{2}at$ at less than full speed. The total distance traveled at reduced speed in one car mile is Nxt feet. Hence the distance traveled at full speed is 5280— Nxt .

$$q_2 = \frac{2RT_1 (5280 - Nxt)}{DKp_1} \dots \dots \dots [25]$$

Each time the car stops, a certain quantity of current is either used or generated and a certain quantity is lost in the resistances.

$$q_4 = \frac{F'Nx_p}{K} - Ny, \dots \dots \dots [26]$$

Ny₁ is negative for the reason that it is a loss, deducted from the generated current.

Summing the several equations

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

IN the end of 1912, Max Jakob stated that the determination of c_p of steam as a function of r from the Clausius thermodynamic relation is extremely difficult, since it depends on the curvature of the isobars in the rT diagram, which is very slight and can scarcely be determined accurately. As a result, equations which have v correct to one-tenth of one per cent may lead to values of c_p several per cent wrong. Professor Goodenough, in his paper published in Vol. 34 of the Transactions of The American Society of Mechanical Engineers, has, however, given an equation for deriving c_p as a function of v . In the present issue is published an abstract of the report of an investigation on specific heat of superheated steam at pressures from 8 to 20 atmospheres, by Knoblauch and Winkhaus, in which, among other things, it is shown that up to 8 atmospheres, the values from the Goodenough equation differ from those found experimentally by less than 1 per cent; and that even in the region of superheat, at pressures as high as 20 atmospheres, it reaches only 2.5 per cent. As the author states, it is a surprising fact that, notwithstanding the inherent lack of precision in the processes of determining c_p from v , the Goodenough equation gives results in such close agreement with observed values.

THIS MONTH'S ARTICLES

Causes of explosions in air liquefaction plants are discussed. In the same section is given an abstract of a discussion of the theory of wind motors and derivation of a formula for the useful power developed by same.

Data of tests on Diesel engines when running light are given, showing, among other things, the variation of the indicated average pressure as a function of the speed of rotation and load.

In the section Mechanics, are discussed torsional oscillations of an engine shaft; in particular, of a Diesel engine having several cranked members, a flywheel and an additional heavy rotating mass, such as a dynamo. The author gives a general method for the determination of the influence of any number of masses on the vibration of the engine shaft. In the same section is given, in abstract, a statement of the laws of efflux of drops from capillary orifices.

The use of centrifugal pumps on fire engines and a description of the various methods of starting such pumps is discussed in an abstract from a German periodical.

In the section Steam Engineering, in addition to the article on specific heat of superheated steam at high pressures and temperatures above referred to, are given statistical data on boiler accidents in France during 1912 and an abstract of an article on the determination of pressure variations in steam turbines and of dimensions of nozzles by means of the Mollier JS diagram.

In the section on Testing is described the Kapff oil testing machine, and some data are given on the bearing of cohesion and adhesion of oils on their properties as lubricants.

The gas power blower station of the Maryland Steel Com-

pany is described in a paper before the American Institute of Mining Engineers.

An abstract of data on tests on concrete, in particular crushing tests and experiences with tremies of various sizes, is reported from the proceedings of the American Society of Civil Engineers.

From the Journal of the Cleveland Engineering Society is taken a very interesting discussion on machine tool development in 1914, showing the trends of development and discussing various new industrial and mechanical features.

The use of electric furnaces for reheating, heat treating and annealing, their field of application and comparative costs, are covered in a paper before the Engineers' Society of Western Pennsylvania.

Henry A. Gardner, in the Journal of the Franklin Institute, reports an investigation of some little understood phenomena in the behavior of paints; in particular, how paints are affected by fungus growths, enzymes and microorganisms.

On a special experimental engine at the University College, Dundee, interesting tests were made on the distribution of heat in the cylinders of a gas engine, reported from an advance paper published by the Institution of Mechanical Engineers.

The subject of pneumatic tubes, both pressure and vacuum, on which there is unfortunately so little published material, is discussed in great detail from rich experimental data by Alec. B. Eason, in the journal of the Institution of Post-Office Electrical Engineers.

Other subjects, such as new methods of the utilization of lignite coal tar, elastic properties of steel at moderately high temperatures, the measurement of the efficiency of domestic fires and handling fuel in extreme climatic conditions, are reported in other sections of the Engineering Survey.

FOREIGN REVIEW

Air Engineering

EXPLOSIONS IN AIR LIQUEFACTION PLANTS AND THEIR CAUSES

There have been several disastrous explosions in plants manufacturing oxygen and nitrogen from liquid air. As a rule, it is quite possible to separate oxygen and nitrogen by fractional distillation in the so-called countercurrent apparatus, but it appears, however, that these apparatus are sometimes subject to highly dangerous occurrences.

The pipes of the column apparatus in which the oxygen is separated from the liquid air have to be thawed out at night because of accumulation of ice. This thawing out process is usually carried out with warm water and, in the meanwhile, the operation of the plant is interrupted. In one case, the attendant was busy thawing out the pipes while a laborer was removing the insulating cork. The foreman had most strictly prohibited the use of a torch, but notwithstanding that the attendant did use one, as he was seen carrying the torch inside. Immediately thereafter, there

occurred an explosion which threw aside heavy iron beams, blew up the roof, killed the attendant and did a lot of other damage. The explosion was followed by a fire. It seems reasonable to believe that the attendant approached with his torch too close to the insulating cork of the column apparatus and in this way ignited the mass. Whether the explosion was due directly to the explosive combustion of the cork or was accompanied by the explosion of illuminating gas has not been established. Tests have shown, however, that the extremely porous cork used in this kind of apparatus accumulates in a very short time such large amounts of oxygen in its pores that it becomes highly explosive.

Another explosion which likewise occurred in an air liquefying plant is also of great interest. It occurred in a plant manufacturing from liquid air pure nitrogen to be used for the production of calcium nitrate. In this case the separation apparatus exploded, mortally wounding the foreman. In this apparatus, the air was compressed to four atmospheres, and was thence led to the liquefaction system where it was allowed to trickle in a column apparatus 3 m. high. The nitrogen evaporated while the oxygen collected in two vessels connected by an overflow. In order to free the nitrogen from the last traces of oxygen, a part of the nitrogen compressed to 100 atmospheres flowed in a thin spiral through the countercurrent helix and through the collector filled with liquid air or oxygen, whence it flowed freely into the upper part of the column. While this was done, the last traces of the oxygen contained in the nitrogen were liquified and flowed down into the collector, and this, as well as the column, was equipped with a safety valve which prevented the pressure therein from exceeding 0.5 atmospheres.

The explosion, which caused a large amount of damage, was not due to excessive pressure, as the presence of a safety valve protected it from that. Two separate detonations appear to have been heard and it seems that the collector was the first to be destroyed, whereupon the oxygen flowing out produced an explosive combustion of the insulating silk. After the first detonation, the foreman rushed to the apparatus but was thrown back by the second explosion, and hurled against a compressor. Previous to that another explosion of a similar nature had taken place, which was ascribed to the fact that in some manner or other the air taken in contained traces of acetylene and that copper acetylide, which is highly explosive, was formed. It does not appear likely, however, that copper acetylide would decompose explosively at a temperature as low as that of boiling liquid air.

The author describes a third explosion which destroyed an entire factory and caused a heavy loss of life. The persons who were in the factory saw a bluish flame, similar to that of lightning, start from the ground. Then a big gray cloud of dust was seen and finally a tremendous detonation was heard, after which the building practically collapsed. Some of the bodies recovered from the ruins were found to be terribly mutilated. The separation apparatus had entirely disappeared and there was an immense hole in the wall near which it stood. From the testimony of the workmen who were in the factory just previous to the explosion, the following is what apparently occurred: The chief engineer and his assistant had started the plant in the morning and it appeared to be working all right. They forgot, however, to blow off the dew which accumulated in the apparatus after it had been standing idle over Sunday and had become some-

what warm. Notwithstanding the most careful cleansing of the air previous to its admission into the liquefaction system, a certain amount of water settled down as ice in the separation apparatus; this had to be melted and removed from time to time. A couple of hours after the plant was started, the foreman inspected it and found everything in order, but apparently the apparatus had simply frozen. When the engineer, who was working the apparatus alone, did not know what to do, he went to the superintendent and was ordered by him to thaw out the apparatus, the superintendent then withdrawing to take care of his clerical work. The engineer, however, notwithstanding strict orders not to bring any fire or hot objects near the apparatus, heated, by a torch, up to red heat, a large wrench used for tightening the stuffing boxes of the expansion valves, and put it into the expansion valve when the insulation of the apparatus apparently caught fire.

Some other cases of explosions in air liquefaction plants are likewise described. From all these, it appears that the causes of explosions may be divided into two classes—one, which is obvious, produced by the prohibited use of an open flame, and the other, less obvious, due probably to some sort of chemical action or freezing.

The author calls attention to the following facts as serving as possible explanations of explosions of the second class. Essentially, air consists of a chemical mixture of oxygen and nitrogen, in addition to which there are present in it, water vapor, carbon dioxide, complex gases and the so-called noble gases, such as argon, metargon, helium, xenon, neon and krypton. The essential properties of these noble gases are that they apparently do not enter into any chemical combination either among themselves or with other gases. The most important of them is argon, of which there is present in the air approximately 0.935 per cent by volume. It liquefies at -186 deg. cent.; oxygen at -184 deg. cent. and nitrogen at -194 deg. cent. In apparatus where nitrogen is produced and where, therefore, a very low temperature has to be maintained, it is quite possible that argon settles down in the pipes, forms an ice-like mass and in this way bottles up the air passages, thus raising the compression of the gas up to the point where it explodes the apparatus.

It is also possible that argon brings about explosions in another manner. Essentially, the noble gases have not a molecular, but an atomic structure; that is, they consist of single atoms. It is, however, possible that this structural property changes at very low temperatures, and in the argon ice the atoms of the gas combine into a complex gas, which dissociates explosively when the temperature rises. Similar explosive dissociations may also take place in the case of peroxide of hydrogen and ozone.

Another source of danger which may cause explosions is the presence of combustible substances in the liquefied air, due, for example, to the penetration of oil from the compressors or perhaps of products of decomposition of lubricating oil formed in the compressors under the influence of the heat of compression. It is also well to bear in mind that in the atmospheric air there are present small amounts of hydrogen and methane, and it is quite possible that if both gases are present in equal amounts they may, after a certain length of time, appear in quite substantial quantities in liquefied air. Considering that air liquefaction plants have usually an output of 400 cu. m. (14,125 cu. ft.) per hour, or 4000 cu. m. per working day of 10 hr., and considering

further that there may quite easily be 0.05 per mil of methane, this would be equivalent to 200 l. (52.8 gallons) of liquid methane, an amount sufficient to create a tremendous explosion in the presence of liquid air or oxygen.

There is one more fact which has to be borne in mind. Ozone may convert hydrocarbons into highly explosive compounds—so-called ozonides or peroxides. Harries produced such explosive compounds even from hydrocarbons having annular formation, such as benzole and toluol, and from other derivatives of methane. Saturated hydrocarbons, such as methane, produce explosive substances of the peroxide type and can be converted into formaldehyde and formic acid. From methane derivatives are also produced ozonides proper, which in most cases are highly explosive, and in the presence of water dissociate into aldehydes and peroxide of hydrogen. Unsaturated ketons, aldehydes and single-base acids of fats combine with four atoms of oxygen thereby also forming explosive compounds. It appears, therefore, that unless extreme care is exercised, there are numerous sources of danger in the production of liquid air and its component gases. (*Beitrag zur Klärung der Explosionsursache in Luftverflüssigungsanlagen*, Dr. W. Bramkamp, *Zeits. für komprimierte und flüssige Gase*, vol. 16, no. 12, December 1914, 5 pp. dp.)

WIND MOTORS

This paper is a discussion of the theory of wind motors, and derivation of formulæ for their design.

Considering an element of a wing resulting from the intersection of a wing by a cylinder of radius r having for its axis the axis of rotation OX , this element rotates about that axis at a speed of n revolutions per sec., and is subjected to the action of a wind blowing at a velocity of V meters per sec. in the direction of the axis. For all points of that element the relative direction of the wind will be the resultant of the velocity of wind V and the tangential peripheral velocity of the element $2\pi nr$. Denoting the angle of this resultant with the direction OX by β , we have the relation

$$\tan \beta = \frac{2\pi nr}{V}$$

The element under consideration is directed along the radius r , so as to make with the direction parallel to OX , an angle $\beta + \alpha$ such that its incidence with the relative wind be α . If we project on the axis OY the two components R_x and R_y of the resistance offered to the element by the air in motion, and multiply these projections by the peripheral speed, we shall obtain an expression for the useful power developed by the element, viz.:

$$dP_u = R_y (\cos \beta - \frac{R_x}{R_y} \sin \beta) 2\pi nr$$

This can be expressed as a function of $\tan \beta$ (which, for the sake of brevity, is denoted by z), in which case we shall have:

$$dP_u = R_y V \left(1 - \frac{R_x}{R_y} z \right) z \frac{1}{\sqrt{1+z^2}}$$

The resistance is

$$R_y = S H^2 K_y$$

where $S = L dr$ is the area of the element, L being its width;

If the resultant velocity, $= \frac{V}{\cos \beta}$, and K_y , unit raising component depending on the section of the element and its in-

cidence α ; further, the ratio $\frac{R_x}{R_y}$ can be replaced by $\frac{K_x}{K_y}$. If we substitute these values into the expression for dP_u , we find:

$$dP_u = \frac{L V^3 K_y}{24\pi n} \left(1 - \frac{K_x}{K_y} z \right) z \sqrt{1+z^2}$$

Assuming that the width of wing L is constant, and is a fraction of the radius, say $1/6$, we have

$$L = \frac{r}{6} = \frac{Vz}{12\pi n}$$

where z is that value of $\tan \beta$ which prevails at the top of the wing. Taking further that the wing is made up by placing side by side, along the radius r , elements similar to the one just considered, all directed in the same way as it with

respect to the resultant of velocities, so that the ratio $\frac{K_x}{K_y}$ is everywhere the same, we can find the formula for the useful power of a wind motor having a wings, by integrating the expression for dP_u between the limits $z_0 = 1$ and $z_1 = Z$:

$$P_u = \frac{a V^3 K_y z}{24\pi n^2} \int_1^Z \left(1 - \frac{K_x}{K_y} z \right) z \sqrt{1+z^2} dz$$

on carrying out the integration between the above limits, we find:

$$\frac{1}{8} \sqrt{1+z^2} - 0.94 + \frac{K_x}{K_y} \left[\frac{1}{8} z(1+2z^2) \sqrt{1+z^2} - z + \sqrt{1+z^2} \right] - 0.64$$

If we denote by $-A$ the term by which $\frac{K_x}{K_y}$ is multiplied, and by B the second term, we obtain

$$P_u = \frac{a V^3 K_y z}{24\pi n^2} \left(B - \frac{K_x}{K_y} A \right),$$

where A and B are positive within the limits of integration. This expression shows that as z increases from $z = 1$, the values of P_u are positive, that they start from zero and rapidly increase, and that P_u again becomes zero for a value of

z such that $B = \frac{K_x}{K_y} A$. The author shows how the maximum value of P_u is determined. (*Sur les moteurs à vent*, M. Drzewiecki, *Comptes rendus des séances de l'Académie des Sciences*, vol. 160, no. 16, p. 513, April 19, 1915, 4 pp. tm.)

Firing

NEW METHOD OF UTILIZING LIGNITE COAL TAR

Lignite coal tar obtained as a by-product from gas producers is usually quite unwelcome because there is no use for it and its elimination involves trouble and expense. Because of its high content of water (up to 40 per cent) it is not commercially profitable to handle. The author in this connection has proposed to reintroduce the tar into the gasification chamber of a producer gas furnace and to gasify it there. This was done and it was found that the otherwise undesirable high water content did not matter here because the water escaped together with the tar, vapors and ammoniacal water and tar coming from the hard coal. A part of the tar vapor, mainly the heavier hydrocarbons, remained, however, in the gas.

The tests were carried out in the following manner: The tar was thrown in the gasification chamber of a producer on the glowing coke cakes and the gas generated in that cham-

her was carried away through a separate pipe direct to the apparatus in the testing laboratory, the tar produced in that chamber being also handled separately. The lignite coal tar was added during the period from the 20th to the 23rd hour of gasification; that is, it was stopped just one hour before the taking out of the coke cake. The amount of tar supplied was 100 kg. (220 lb.), approximately the same as is taken out in producer gas production per chamber.

The tests have given the following results. Before the beginning of the coal tar additions, the gas had an average heating value of 3580 calories (844 B.t.u. per lb.) at zero deg. cent. and 760 mm. barometric pressure. During the

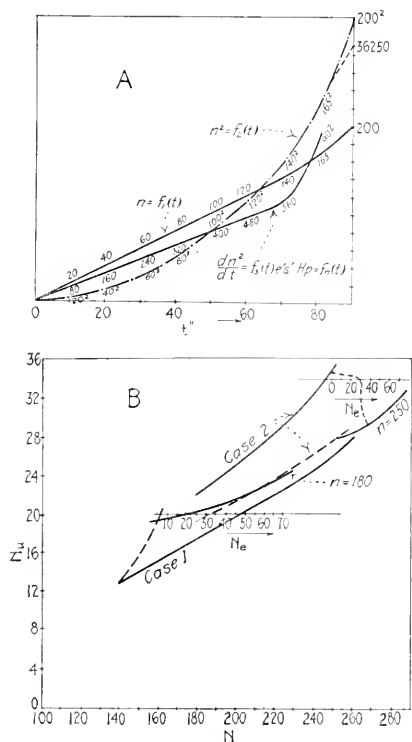

FIG. 1. CURVES FROM TESTS ON DIESEL ENGINES WHEN RUNNING LIGHT

period of addition of the tar it stood around 3950 calories (7110 B.t.u. per lb.), which indicates that unless the lignite coal tar were added, the heating value of the gas during these three hours would, instead of rising, have sunk from 3580 to 3420 calories and probably even below that. The author shows further that the gases produced from the tar were equivalent to 229,600 calories, equal to 44 cfm. of gas of 5200 calories (9360 B.t.u. per lb.).

The author goes through a detailed calculation and shows that in the above escaped gas the lignite tar had at least a value of 3.40 marks per 100 kg. (\$0.36 per 220 lb.). (*Ueber ein neues Verfahren zur Verwertung des Braunkohlenteers*, Viktor Schön, *Journal für Gasbeleuchtung*, vol. 58, no. 17, p. 216, April 24, 1915, 2 pp. d.)

TESTS ON DIESEL ENGINES WHEN RUNNING LIGHT

No-load runs on Diesel engines can be classified in three groups: *First*, no-load runs without ignition in the cylinder, which occur, for example, when, in a two-cylinder motor, one cylinder drags the other; *second*, no-load runs with ignition but without load, in which case only enough power is developed in the cylinder to overcome friction; and *third*, running light with ignition under load on the engine.

The no-load run proper is necessary to overcome all the internal resistances and depends, therefore, partly on the design and partly on the workmanship of the engine. The action of the flywheel has to be considered separately in this connection, as, because of air friction and windage, it often takes up quite a considerable amount of horse-power, increasing as the third power of the speed of rotation. With our present state of experimental information on this matter, it is difficult to determine analytically the amount of power consumed by a flywheel, while it is also difficult, if not impossible, to carry out a comparative test without a flywheel. If the speed of rotation is constant, the influence of the flywheel may naturally be neglected because the amount of work done by the flywheel can hardly vary; otherwise, the re-

sults obtained will be somewhat lacking in precision.

The experiments described below have been carried out on a single cylinder Diesel engine of 50 h.p., on which, by varying the speed, an output as high as 70 h.p. could be secured.

The moment of torsion is

$$M_d = I_p \frac{d\omega}{dt} = I_p \frac{\pi}{30} \frac{dn}{dt} \dots \dots \dots [1]$$

where I_p is the polar moment of inertia of the flywheel in kgm. sec.², ω the angular velocity in sec.⁻¹, and n the r.p.m.

TABLE 1 DIESEL ENGINE RUNNING AT LIGHT LOAD

of the engine. In order to produce this moment of torsion is required the work

$$L = M d\omega = \frac{9.86}{1800} I_p \frac{dn^2}{dt} \dots \dots \dots [2]$$

and to calculate L , it is necessary to determine I_p and n as a function of time t . The value of I_p can be determined either experimentally or analytically, the latter being somewhat uncertain. In the present case, the analytically determined weight of the fly-wheel differed from that determined by actual weighing by 1.4 per cent, which tends to show that the mass used for the determination of I_p has been selected with sufficient precision to satisfy practical requirements. Such a calculation gave for I_p a value of 310 kgm.sec.².

$n = f_1(t)$ was determined experimentally. The power was shut off, the engine allowed to slow down freely and in 10 minutes the speed of rotation was read by a tachometer. The results obtained in this way are plotted in Fig. 1A as $n = f_1(t)$ (scale 1mm = 0.039 in. = 2 revolutions); $n^2 = f_2(t)$ is also plotted (scale 1mm = 0.039 in. = 250 n²).

By graphic differentiation, the third curve

$\frac{dn^2}{dt} = f_3(t)$ was drawn to such a scale that 1mm = 10.

Equation [2] becomes in this case,

$$L = 1.72 \frac{dn^2}{dt} \dots \dots \dots [3]$$

The results thus obtained are presented in Table 1A, in which the last column gives the power consumption. The last series of figures in this table are not fully reliable, because an element of uncertainty crept into the construction of the tangent. These figures have been plotted on the diagram of Fig. B with the notation "Case I." This curve from $n = 140$ on has been plotted approximately.

Tables B and C give the data of tests made on the same engine at constant speed: $n = 180$ r.p.m. and $n = 250$ r.p.m. In these tables Ne denotes the effective horse-power, Nu , the horse-power at no load, pr , the average pressure at no load in kg/cm² (1 kg/cm² = 14.22 lb. per sq. in.).

For plotting the curve, ("Case 2"), can be applied only a method in which interpolation is used, because with the present design of Diesel engine a "stationary" no-load operation is very difficult to obtain, and properly conducted tests at no-load always show a higher output of work than at load. By means of interpolation, however, from the actual no-load work can be obtained the "ideal," if, as shown in Fig. B, Nu be plotted as a function of Ne and the curve extended to $Ne = 0$. In this way the dotted curve for the "ideal" no-load work, ("Case 2"), is determined. The actual no-load curve lies above the dotted line and is shown for "Case 2" in full line. If it be desired to draw a comparison between no-load works at different speeds of rotation and at different loads, the indicated average pressure pr must be considered. In Fig. C, the values of pr given in Tables 2 and 3, are plotted as functions of the effective horse-power. This diagram shows that at high loads (that is, *not* at no-load) the indicated average pressure of no-load decreases as the speed of rotation increases. This is shown with particular clearness from Fig. D, representing the data obtained in the tests of Seyliger (*Zeits. des Vereines deutscher Ingenieure*, 1911, p. 587).

These tests are transferred also to Fig. E, where, as abscissae, are used the effective horse-power, and as ordinates, the speed of rotation, the values of pr being assumed respectively constant. These curves show at once that the no-load work, at the same effective load, does not increase in direct proportion to the speed of rotation, but remains somewhat below proportionality. Nevertheless, the mechanical efficiency for the same value of effective load must decrease with the speed of rotation. From Fig. E can be seen the values of pr and n for the effective load $Ne = 225$. Since, however, the indicated work is

$$Ni = C p^2 n$$

where C is constant, and since it increases in the present case, notwithstanding the fact that Ne remains constant, it follows that, while the work increases, the mechanical efficiency decreases. If the speed of rotation increases, the in-

$$\begin{vmatrix}
 K_{11} + K_{12} - \alpha^2 & -K_{22} & 0 & 0 & 0 \\
 -K_{12} & K_{22} + K_{23} - \alpha^2 & -K_{23} & 0 & 0 \\
 0 & -K_{23} & K_{33} + K_{34} - \alpha^2 & -K_{44} & 0 \\
 0 & 0 & -K_{34} & K_{44} + K_{45} - \alpha^2 & -K_{45} \\
 0 & 0 & 0 & 0 & 0
 \end{vmatrix} = 0 \dots \dots [1]$$

dedicated average frictional pressure decreases for the same value of N_e , which leads to a lower mechanical efficiency.

Attention must further be called to the fact that the larger the dimensions of the cylinders or the greater the units under investigation, the smaller becomes the value of μr . In practice, it has been found that in multicylinder motors, μr per cylinder decreases also.

Further, there must be taken into consideration, also, the influence of the air pump. In the above described tests, the air pump, which plays an important role in the determination of mechanical efficiency, has been taken into account because that corresponded to the actual conditions.

Fig. 2 Torsional Oscillations of a Diesel Engine Shaft

In order to draw comparisons, more precise investigations should be carried out, with and without counting the air pumps. Practically, however, this did not constitute any serious mistake, because the power consumption to the air pump in very large units is negligibly small as compared with the total output. Mechanics

Torsional Oscillations of an Engine Shaft

The article is an investigation of the influence of torsional oscillations on the behavior of a Diesel engine shaft.

In the case of a Diesel engine which developed irregularities in action after passing a certain speed of rotation, it appeared likely that this irregularity may have been due to torsional oscillations. The shaft had four cranked members, a flywheel and, next to it, a dynamo. Therefore, apart from the mass of the shaft proper, these masses might have been taking part in the torsional oscillations; the moments of inertia of the flywheel and dynamo were, however, so much in excess of these others that they should have had a determining effect on the natural frequency of vibration of the shaft. At first glance, it did not seem possible to ascertain how great an influence was to be ascribed to the other masses and this necessitated an analytical method of calculation, which finally led to the method described in this article, permitting the determination of the influence of any number of masses on the vibration of the engine shaft.

Fig. 2 shows diagrammatically a shaft with a fairly large number of masses of which the moments of inertia about the axis of the shaft are indicated by J_1, J_2, \dots, J_n . The num-

ber and type of the bearings are not considered here because no attention is paid to the moments of friction; the air resistance exerted on the surface of the rotating masses is also left out of consideration. If a shaft develops free torsional oscillations, it is acted on by moments of torsion which vary

by the amount $J_1 \frac{d^2\phi_1}{dt^2} = J_1\phi_1$, only when the moment of

inertia of a mass exceeds J_1 and the instantaneous angle of torsion against the vertical (Fig. A) exceeds ϕ_1 . The section of the shaft located between the i -th and the $(i+1)$ th masses is twisted by the moment of torsion M_i through the angle ϕ_i for which case the relation $M_i = C\phi_i$ holds good,

By a process of mathematical analysis which has to be omitted here because of lack of space, the author arrives at the following two equations which fully determine the behavior of a shaft under conditions stated above:

and

$$\varphi_1 = \sum C_k \gamma_k \sin(\alpha_k t - \delta_k)$$

$[i=1, 2, \dots, n-1; K=1, 2, \dots, n-1]$ where

$$-\frac{C_1}{J_1} = K_{11}; \quad \frac{C_1}{J_2} = K_{12}; \quad \frac{C_2}{J_2} = K_{22} \quad \text{etc.}$$

γ with its subscripts refer to constants depending for their magnitudes on the constants of the shaft and masses held on it. The difference of angles (cp. Fig. A) $\phi_2'' - \phi_1'' = \varphi_{11}''$ and

$$\alpha = \frac{\varphi_{11}''}{\varphi_1}$$

[1] is an equation of the $(n-1)$ th power for the $(n-1)$ values of $\bar{\omega}^2$ which can be solved by any known analytical or graphical methods. When forced oscillations arise, one may expect as many resonances as there are values of $\bar{\omega}^2$. In most cases the minimum value of $\bar{\omega}$ is of interest, and it can be usually determined approximately. This being done, the determinant of [1] is calculated with several values of $\bar{\omega}$ near to the value found approximately (which is not difficult even with a large number of masses because of the many zeros in the determinant), and the values of the determinant are plotted on a system of coördinates as a function of $\bar{\omega}^2$. A curve through the points thus found gives a sufficiently close approximate value of $\bar{\omega}$.

Actually, because of the damping of oscillations, the greatest deflection will occur with the smallest $\bar{\omega}$, and even before that the deflections will become excessively large. Further, in order to avoid excessive vibrations, it is necessary to have the smallest periods of free oscillations considerably greater than those of the forced oscillations.

The following example shows the application of the above process. For the case discussed above, it is assumed that the oscillations are due mainly to the action of the flywheel and dynamo, here considered as masses 5 and 6 (the four cranked sections are denoted as 1 to 4). Then, from equation [1]

$$K_{55} + K_{66} - \bar{\omega}^2 = 0,$$

or

$$\bar{\omega}^2 = K_{55} + K_{66} = \frac{C_5}{J_5} + \frac{C_6}{J_6}$$

It was further found that for the flywheel $J_5 = 500,000$ kg·cm·sec.², and for the dynamo $J_6 = 36,000$ kg·cm·sec.²,

while C_1 (constant for the section of the shaft between fly-wheel and dynamo) is 1.68×10^6 kg cm. Hence

$$\delta^2 = 5006 \text{ and } \delta = +70.8$$

which corresponds to a speed of $\frac{70.8 \times 30}{\pi} = 677$ r.p.m.

The author shows further that the presence of the cranked portions of the shaft does not materially affect the oscillatory process.

Harmonic analysis of the tangential pressure diagram indicates that resonance is likely to occur only with moments of the second or fourth order. It was therefore to be ex-

subject to sudden increases so that at high velocities the weight of the drop may be substantially greater than that which it had when it passed through the first maximum.

The author made a series of tests with 15 tubes of different external and internal diameters, the internal diameters varying from 0.4 to 2.4 mm. and the external diameter from 2.3 to 7 mm. He expresses the results obtained in the following four laws:

First. The product of the internal diameter d by the interval of time between two drops T , corresponding to the first maximum is a constant A , or simple multiple of this number. From the frequency zero to that which corresponds

FIG. 3. STARTING DEVICES FOR FIRE ENGINE CENTRIFUGAL PUMPS

pected that material oscillations would arise at speeds of $n = \frac{677}{2} = 339$ r.p.m., or $n = \frac{677}{4} = 169$ r.p.m. Actually, however, the speed of the engine, because of oscillations, could not be brought above 162 r.p.m. (*Torsionsschwingungen einer Dieselmotorwelle*, Otto Mies, *Dinglers polytechnisches Journal*, vol. 330, no. 6, p. 101, March 20, 1915, 3 pp., 1 fig. (m).)

LAWS OF EFFLUX OF DROPS FROM CAPILLARY ORIFICES

In a previous note, the author has shown that the weight of drops escaping from a capillary orifice is a rather complicated function of the frequency of fall. As this frequency increases, the weight of the drops at first increases, passes through a maximum, and then decreases rather rapidly, being, however, at certain critical values of frequency

to the first maximum, the weight of the drops varies nearly in a straight line with the frequency (after the passage of the first maximum the inverse variation becomes more rapid). This straight line as defined above determines, by extrapolation, the weight P_0 corresponding to frequency 0. This being so,

Second. Quotient of the increase of weight $\delta = P_m - P_0$ of the drop from the origin to the first maximum by the internal diameter d is a constant number B or a simple multiple of that number.

Third. A quotient of the weight P_0 (at the origin) by the external diameter D is a constant number C . C is, however, different from B and in addition to that for tubes for a diameter in excess of 5 mm. it is different from that for tubes with a smaller diameter.

Fourth. From the instant of sudden increase of the

weight of the drop, the quotient of this increase of weight or to a simple multiple of it. (*Sur les lois d'écoulement par gouttes par les orifices capillaires*, E. Vaillant, *Comptes rendus des Séances de l'Académie des Sciences*, vol. 160, no. 18, p. 596, May 3, 1915, 3 pp., te.)

Pumps

CENTRIFUGAL PUMPS FOR FIRE ENGINE SERVICE

The article discusses the use of centrifugal pumps on fire engines, a test of such pumps carried out in the Berlin Fire Department Works, the priming of pumps by various means, and their designs.

In Berlin, two types of fire engine equipment are used—one storage battery driven and the other pure gasoline driven. During the recent tests of the storage battery driven engines, it happened that after the engine had been running for about 48 km. (29.8 miles), the current began to give out. The car was immediately shifted into a side street and the battery recharged right on the spot by a gasoline engine intended for driving the pump. For use in case of fire in

the air in the centrifugal pump and in the suction piping, and thereby forces the water column to rise by suction. As soon, however, as the water has risen sufficiently, and the blade wheel is enabled to create a difference in pressure between the suction and pressure chambers, there is created an axial thrust on the blade wheel which forces it away from the air pump. The axial thrust is created through the difference in dimensions of the diameters of the lateral packing rings of the blade wheel. When the machine stops, the coupling of the air pump with the centrifugal pump is restored through the action of the spring.

In the estimation of the author considerable difficulty lies in the design of a suitable air pump. The so-called rotary pumps can be applied only with considerable difficulty because of the high speed used here in most cases. Besides, it is difficult to eliminate entirely the axial thrust, which is studiously avoided in all other types of centrifugal pumps. It appears, however, that good results were obtained with this arrangement at low speed, say, 600 r.p.m.

In the fire pump covered by the French patent 435,557 and shown in Fig. B, a special reciprocating pump is used

for creating a vacuum in the centrifugal pump. The vacuum pump is built in directly on the centrifugal pump, and in the piping leading from the centrifugal pump to the air pump is placed a cock by means of which the air pump can be shut off from the centrifugal pump. Formerly, there was provided in the same piping a screen to prevent foreign bodies from entering the air pump; the latter is so built, however, that the water that may penetrate into it will do no harm. This pump was once used as an auxiliary pump in a water supply system, and it was found that the centrifugal pump ran for ten days against a suction head of 9 m. (26.2 ft.) without having once broken off the water column.

The German patent 200,765 (identical with the English patent 20,595) utilizes the suction of one or more cylinders of a multicylinder explosion motor for the priming of the centrifugal pump. The patent specifically provides for the interposition of a float in the connecting piping, whereby the entrance of water into the cylinder or cylinders of the motor is prevented. The float valve is arranged in such a manner that, as soon as the rise of water connects with the atmosphere, the further suction of water is stopped. If it proves possible to keep the water from the cylinders of the engine, the practical value of this invention is quite considerable; otherwise, it is of no value.

The French patent 429,270, belonging to the same English concern, utilizes for this purpose the arrangement shown in Fig. D. In the connecting piping is inserted a tank *a* filled up to a certain level with mercury. Around the pipe *b* reaching down into the mercury, is concentrically located the pipe *c*, the lower end of which is immersed in the mercury while the upper end is provided with openings, *d*. With

suburbs, however, engines with a pure gasoline drive are used exclusively.

One of the difficulties to be overcome in the design of a centrifugal pump lies in the fact that the pump is not self-starting, and requires some auxiliary device either for creating a vacuum to raise the water from water level to the pump or for priming. This is done in several different ways; for example, German patent 263,112 employs a rotary air pump coupled directly to the shaft of the centrifugal pump and arranged in such a manner that, after the latter is filled with water, the air pump is automatically uncoupled from the centrifugal pump. As shown in Fig. 3A, on the prolongation of the shaft of the centrifugal pump is placed one-half, *a*, of a removable friction coupling, while the other half, *b*, is on the shaft of the air pump. When the aggregate is at rest, the air pump, because of the action of the spring *c*, is coupled with the centrifugal pump and the rotary part of the latter is displaced towards the suction side. If, however, the aggregate is started, the air pumped through pipe *d* sucks

properly adjusted cocks *e* and *f*, the suction of the air pump forces the water into the tank *a*, delivers it through slot *g* into *h* and causes such a rise in the level of the mercury in pipe *b* that the opening of this pipe is cut off by the mercury. If the vacuum increases still more, the mercury rises to the level *i*, whereby the entrance of the water into the pump is cut off.

Of the several devices utilized for starting centrifugal pumps, the arrangement for maintaining a reserve of water on the pump shown in Fig. E is typical. (Patented in Germany, no. 255,461). Since the suction elbow of the centrifugal pump is directed upward, when the pump is stopped, it remains filled with water, and the pump should start when the cut-off valve *a* is closed, while the air cock *b* and valve *c* are open. In such a case, the water which collects in the pressure space *d* is led through the runner *h*, and along the ribs *g*, this taking place in such a manner that the two spaces *i* and *k* are filled with water while, in the middle space *l*, there

nects the close water tank with the ejector, has to be opened.) Because of the suction on the water, a vacuum is created in the tank *e*, and this, with cock *f* opened, results in water being sucked into the centrifugal pump *g*. By means of suitable adjustment of the cocks *d*, *f* and *h*, the suction into and the filling of the centrifugal pump can be regulated and the tank can be filled with, or emptied of, water. (*Kreiselpumpen für Feuerlöschzwecke*, Alfred Schacht, *Die Förderungstechnik*, vol. 8, nos. 8 and 9, p. 57 and 67, April 15 and May 1, 1915, 8 pp., 14 figs., *d*).

Steam Engineering

SPECIFIC HEAT OF SUPERHEATED STEAM AT PRESSURES FROM 8 TO 20 ATMOSPHERES, AND FROM TEMPERATURE OF SATURATION TO 380 DEG. CENT.

For a considerable time, in the laboratory of Technical Physics, in Munich, extensive experiments on the determina-

FIG. 4 c_p ISOBARS IN THE c_p t DIAGRAM

occurs an injector-like action due to the fall of water. The mixture of water and air coming from the runner is led into the pressure space *d*, provided with an air reservoir *m*, and from *d* the air sucked in, is allowed to escape through the cock *b*. When water starts to come out from this cock, it shows that the pump is filled with water, then the cut-off valve *a* can be opened and the pump operated in the usual manner.

An interesting design (French patent 400,696) is shown in Fig. C, the fundamental principle of which is the use of the exhaust gases of an explosion motor driving the pump, to drive an ejector by means of which the pump is started. When the pump is to be started, the exhaust gases are delivered into the chamber through pipe *b* into the ejector *e*, not through pipe *a*. (Previous to that the cock *d*, which con-

nects the close water tank with the ejector, has to be opened.) Because of the suction on the water, a vacuum is created in the tank *e*, and this, with cock *f* opened, results in water being sucked into the centrifugal pump *g*. By means of suitable adjustment of the cocks *d*, *f* and *h*, the suction into and the filling of the centrifugal pump can be regulated and the tank can be filled with, or emptied of, water. (*Kreiselpumpen für Feuerlöschzwecke*, Alfred Schacht, *Die Förderungstechnik*, vol. 8, nos. 8 and 9, p. 57 and 67, April 15 and May 1, 1915, 8 pp., 14 figs., *d*).

The formula for c_p is derived in the following manner: Mollier derived for the heat of generation of steam i (that is, heat, in kcal., which must be supplied to 1 kg. of steam at 0 deg. cent. to convert it, without altering the pressure, into 1 kg. of steam at t deg. cent. and p kg. per sq. cm. pressure) the following formula:

$$i = 594.735 + 0.477 t - J_p$$

where J is a function of t only, and Mollier gives its numerical values in a table. The small fall-off in pressure

corresponding to a small increase in the heat of generation of steam Δi is therefore approximately $\Delta i = J\Delta p$, and since this amount of energy has been taken from a source of electrical heat at the point of the experimental apparatus denoted as u , the amount available there for the superheating of the steam becomes $[(W - I) - GJ\Delta p]$ where W is the total amount of electrical energy shown by the meter, I heat losses, and G weight of steam flowing through per hour. This gives for c_p , the following expression:

$$c_p = \left[\frac{W - I}{G} - J\Delta p \right] \frac{1}{t_s - t_1}$$

The original article contains a table (Table 2) of values of specific heats calculated by means of the above equation. In Fig. 4 these values of c_p have been plotted as ordinates over temperatures, as abscissae, and curves have been drawn through them connecting points of equal pressure. In plotting these c_p -isobars, drawn for 0.5, 1, 2, . . . , 20 atmospheres certain methods of equalization had to be resorted to, in addition to which the behavior of c_p at the critical point, and the dependence of the total heat i on pressure had to be considered. At the critical point, c_p must become infinitely great. Hence, if all the c_p -isobars be extended to the left to the point of saturation, and the terminal points be connected by a curve, this c_p -saturation curve will reach at the critical point the value $c_p = \infty$.

The total heat i (which has to be supplied to 1 kg. of water at 0 deg. cent., to convert it at the same pressure into steam of a given temperature) is, at a given temperature, greater for lower pressures than for higher ones. The c_p -isobars therefore have to be drawn in such a manner that they give for i values which satisfy this dependence on pressure.

In Fig. 4 is shown, dotted, also the curve obtained by extrapolation for zero atmospheres.

The comparison of these isobars with those of Knoblauch and Mollier for 2, 4, 6 and 8 atmospheres indicates, in the region of superheat, only very slight differences, but on the saturation line the values have to be lowered considerably as compared with the former ones, in order to bring them into accord with those determined at higher pressures.

The author compares his results with those of M. Jakob (*Zeits. des Vereines deutscher Ingenieure*, 1912, p. 1980) and G. A. Goodenough (*Trans. A. S. M. E.*, vol. 34, p. 507), who both start with the Clausius thermodynamic equation, with the difference, however, that Jakob determines c_p from r while Goodenough attempts to do the reverse.

Jakob used an equation of state of steam derived from the determinations of Knoblauch-Linde-Klebe, and, within the region of validity of this equation finds, between values of r calculated from the equation and those determined by measurement, differences below 0.25 per cent, a truly excellent agreement. But at higher pressures in the region of superheat, the deviations of the values of r as determined by the Clausius formula from those found by observation, are much greater, and the difference at 19 atmospheres and 300 deg. cent. amounts to 1.1 per cent.

The agreement between the measured values and those calculated by the Goodenough equation is naturally less close, because, as has been shown in technical literature, the double differentiation in t , required in the Clausius formula to determine c_p from r , changes very materially the value of c_p even when the error in the value of r has been very slight. Nevertheless, up to 8 atmospheres and 550 deg. cent., the

values from the Goodenough equation differ from those found by the author, by less than 1 per cent, but gradually become less as the region of saturation is approached. For average and high superheats, however, the differences between the calculated (from the Goodenough equation) and observed values is not great even for higher pressures, and, e.g., at 20 atmospheres and 350 deg. cent., reaches only 2.5 per cent, the calculated values being the smaller ones.

The authors believe that a slight variation of the Goodenough equation or constants used in it might give as good an agreement for the higher pressures as for pressures up to 8 atmospheres. It is surprising that, notwithstanding the inherent lack of precision in the process of determining c_p from r , the Goodenough equation gives results in such a close agreement with observed values.

The authors believe that what has been found in the case of steam as to the dependence of specific heat on pressure and temperature applies also to other gases of which the molecules consist of several atoms. As a matter of fact, Scheel and Hense have already found, in the case of atmospheric air in the neighborhood of its point of condensation, that c_p increases as the temperature goes down. BOILER ACCIDENTS IN FRANCE IN 1912

The table below is taken from a compilation from official reports on boiler accidents. The data are tabulated, and give: date of accident; kind and location of plant in which it occurred; kind of apparatus; brief statement of circumstances; number of killed and wounded; supposed cause of accident.

Table 3 is a resume of these data.

(*Bulletin des accidents d'appareils à vapeur survenus pendant l'année 1912. Annales des Ponts et Chaussées*, vol. 24, ser. 9, no. 6, Technical part, p. 626, November-December 1914, 16 pp., *sd.*)

per unit of time, is given, it is possible, when the shape of the blade is likewise given and its cross-section f is known, to determine for every point the value of the right side of the equation of continuity $\frac{G}{f} = \frac{c}{v}$, where G is the weight of steam per second, f cross-section of flow, v specific volume and c velocity. If it be further assumed that the initial state of the steam expanding in the diaphragm is known, then the velocity c , at any point of heat content i , can be determined from the difference in temperature. If this value be inserted on the right side of the equation of continuity, it serves to determine the specific volume v at that place. It is now possible to determine by means of the curves of equal volume in the JS diagram, on the horizontal line characterizing the heat content i , a point for which the specific volume is v .

If the same process be repeated under the assumption of

FIG. 5. CURVES OF PRESSURE VARIATION IN STEAM TURBINE AND NOZZLES

DETERMINATION OF PRESSURE VARIATION IN STEAM TURBINES AND OF DIMENSIONS OF NOZZLES BY MEANS OF THE JS DIAGRAM

The present article is an abstract from a book published by Doctor G. Zerkowitz, under the title "Thermo Dynamics on Turbo Machinery" (Thermodynamik der Turbomashinen).

The author, who uses the JS diagram of Mollier, denotes his process as a method of geometric loci, since for the determination of the state of steam at any point in the turbine, he draws on his diagram two curves, one of which satisfies the condition of continuity, while the other contains all the points corresponding to the equation of energy: $\Lambda \frac{c^2}{2g} = i_1 - i_2$, where Λ is the mechanical equivalent of heat, c velocity, g coefficient of acceleration or free fall, and i_1 and i_2 the heat contents at two different points of the stream of steam. The point of intersection of these two geometric loci represents the point of state sought for.

The determination of the state of the steam when it leaves the distributor may be used as an example. Under the assumption that the weight of the steam G , flowing through

different heat contents and the points corresponding to different specific volumes v be connected with each other, then, as Fig. 5A shows, there will be obtained a line curve $Y'Y''$, which satisfies the equation of continuity. Further, assuming a certain loss of energy in the blading, the process of expansion may be represented by a curve $E'E'$, which corresponds to the equation of energy. The point of intersection A_{2d} of these two curves satisfies both conditions and characterizes the state of the steam after it leaves the distributor. If A_1 denotes the state in front of the distributor and use is made of the velocity of outflow in the preceding stage, then the fall in heat corresponding to this velocity is plotted from A_1 up to A_0 , and the fall A_0X is used as a basis for the calculation of c . The second point of intersection A'_{2d} of the geometric loci is determined for turbines having a velocity in excess of that of sound, while the point S at which the tangent of the Y curve is vertical denotes the entrance of adiabatic velocity of sound.

The determination of the process of variation of pressure is of practical value in the investigation of the governing of turbines. If, however, for example, p_m denotes the pressure in front of the m -th stage at full load, p_{m+1} the pressure in front of the $(m+1)$ th stage under the same con-

ditions, while $p'm$ and $p'm + 1$ denote pressure at part load, then it can be often shown that $\frac{pm+1}{pm} = \frac{p'm+1}{p'm}$. Therefore the velocities of outflow in the separate stages are constant. If such is not the case, then the efficiency varies; and also the ratio of peripheral speed to the velocity of steam may deviate more or less from the most advantageous line.

For the graphical calculation of nozzles, the JS diagram may be also used to advantage. For the solution of this problem, a curve of state is used which diverts from the vertical adiabat to the right; then the pressures p are plotted, which can be found from the diagram and correspond to single points (Fig. B). These pressures are plotted

Testing Machinery

PROFESSOR VON KAPFF'S OIL TESTING MACHINE

This paper describes the oil testing machine designed by A. von Kapff. While this machine is not new, it is described in detail because it is not mentioned in such works in the English language as "Lubrication and Lubricants," by L. Archbutt and R. Mountford Decey (London 1912), and "Lubricating Oils, Fats and Greases," by George H. Hurst (London 1911).

The properties of a lubricant essential for the determination of its lubricating value are its cohesion and adhesion. Cohesion, sometimes also denoted as viscosity, is the internal friction of the oil and the thicker the oil, the more work is necessary to overcome this. On the other hand, the ability of the lubricant to maintain a film of oil between the surfaces in friction and thus prevent their seizing and overheating, depends upon the adhesion of the oil. The greater the pressure between the surfaces in friction the greater must be this adhesion, since otherwise the oil would be forced from between the surfaces.

As a rule, in a lubricant adhesion and cohesion go together; that is, when the oil holds well between the surfaces in friction, high internal friction goes with it. In oils of equal cohesion, however, the adhesion may be quite different, and vice versa. Therefore, the determination of the internal friction, which is the only thing that can be made by means of a viscosimeter, gives only a very rough idea of adhesion and value of lubricant as compared with other oils in reduction of power consumption. It is only by means of a regular oil testing machine that this can be done and, for example, the two diagrams, Fig. 6 M and N, show to what degree the action of oils depends on temperature and pressure. The oil A, Fig. M, consumes at low pressure less power than oil B and is therefore more suitable for the lubrication of spindles or bearings under low pressure, while B is more adapted for high pressure bearings. Fig. N shows two kinds of cylinder oils, A, maintaining its lubricating properties at high temperature while B loses its lubricity at about 170 deg. cent. (338 deg. Fahr.). Therefore, the fuel consumption and oil consumption with B is considerably greater than with A.

The oil testing machine of Professor von Kapff is shown in Fig. O, where A is a speed counter set on the motor axis, consisting of a glass tube, graduated and partly filled with liquid. As the speed increases, the air bubble in the tube comes down, thus indicating the speed. Experience has shown that the best comparable results obtained at speeds varying between 3000 and 7000 revolutions, while spindle oils can be tested at 6000 to 7000 revolutions. The speed is adjusted first by the heavier rheostat G and then by a finer rheostat F, actually located on the switchboard. When two oils are tested for purposes of comparison, the speed, temperature and pressure should naturally be the same. When the speed counter is taken off and then put on again, it is important to set it centrally.

In Fig. O B indicates the housing for the electric motor; C are for terminals connected with similar terminals on the switchboard; D is the connecting link between the axis of the motor and the friction spindle E, rigidly connected with the motor shaft by means of an adjusting screw F (this F, and the following G, are different from similar letters used by the author to denote the rheostats). Over the upper part of the friction spindle (fork shaped) is set a bush H, likewise

FIG. 6. KAPFF OIL TESTING MACHINE AND CURVES OF TESTS OF OILS

as abscissa, and over them are plotted as ordinates, the specific weights γ , as well as the velocities w , which can be read off on a scale on the side of the Mollier table. Likewise as ordinates the values of the product γw are plotted and then, by means of the equation of continuity, the cross-sections f are calculated and plotted on the diagram.

For practical purposes it is sufficient to determine by the formula the critical pressure; then the smallest cross-section and finally, under the assumption of expansion to any desired counter pressure, the cross-section of the outflow. (*Berechnung des Druckverlaufs in einer Dampfturbine sowie der Düsenabmessungen mit Hilfe des JS-Diagramms*, Schmolke, *Dinglers polytechnisches Journal*, vol. 330, no. 8, p. 152, April 17, 1915, 2 pp., 2 figs. t.)

provided with an adjusting screw *G*. When the oil tank *J* is either taken out or put in again, the screw *G* is screwed in hard, *H* lifted up and then screw *G* loosened. When the tank is set right so that the mark *I* coincides on the casing with the mark made at the foot of the tank, the screw *G* is again loosened, *H* set over the upper part of the spindle and screw *G* driven in hard once more. The screws *K* connect the tank rigidly and centrally with the casing. *L* a thrust journal upon which the spindle runs. The pressure is provided by a separate pressure element *M*, on the upper part of which is located the loading lever not shown in the drawing, *N* is a thermometer inserted through an opening on top of the tank into the oil. (In Fig. 6 the thermometer is shown bent, but it may also be straight.)

For spindles and transmission, oils are used with temperatures from 20 or 60 to 100 deg. cent. (68 or 140 to 212 deg. Fahr.); for cylinder oils, temperatures from 100 to 350 deg. cent. (212 to 662 deg. Fahr.). The tank *J* is filled nearly up to the edge with the oil to be tested. When the oil has to be changed the tank is emptied, washed with kerosene and then with gasoline. For heating the oil in the casing, an opening *O* is provided under which a good Bunsen burner may be placed.

Before the current is turned on and the motor started, it is well to bring the oil up to approximately the desired temperature; then the speed of rotation is regulated by means of the rheostat until the voltmeter and ammeter have remained stationary for some minutes at the desired temperature and speed of rotation. For regulating the pressure, two weights are provided. Spindle oils and light bearing oils are tested at pressures of about 2 or 3 kg. (28.44 to 42.66 lb. per sq. in.); transmission oils at about 10 to 20 kg. (142.2 to 844 lb. per sq. in.) and cylinder oils at 5 to 10 kg. (71.1 to 142.2 lb. per sq. in.). If at a given pressure the apparatus runs irregularly,—that is, if the speed and power consumption vary by jumps,—it shows that for the given oil the pressure is too high. The speed of rotation of the motor should be clockwise when looked at from above. The apparatus is arranged to run on 110 or 220 volts, d.c., and consumes about 1 3 h.p. (*Oelprüfungsmaschine von Prof. von Kapff, Petroleum*, Vol. 10, no. 14, p. 543, April 21, 1915, 3 pp., 4 figs. d.)

Modern Gas-Power Blower Stations, Arthur West (abstracted).

Fire-Fighting Methods at the Mountain View Mine, Butte, Mont., C. L. Berrien.

Conversion Scale for Centigrade and Fahrenheit Temperatures, Hugh P. Tiemann.

MODERN GAS-POWER BLOWER STATIONS, Arthur West.

The paper describes briefly some recent large blower installations for blast furnaces where the blast is supplied exclusively by gas engines using furnace gas. The following installations are described: Bethlehem Steel Company, eleven engines; Minnesota Steel Company, at Duluth, five engines; Maryland Steel Company, at Sparrows Point, five engines.

The most recent of all of these installations is that of the Maryland Steel Company, and it presents several unusual features. In the first place, although the engines are the same size as those at the Bethlehem and Duluth plants, they are set diagonally in the house, which gives more room

around them with the powerhouse 20 ft. narrower. The length of the house is not increased, both because the out-board bearings over-lap each other and because there is room left in the triangular space at the end of the station for a railroad car to enter under the traveling crane, but with engines set squarely across the house at least one extra panel must be provided to allow the entrance of such a car. Because of the lesser span, the costs of both the roof trusses and the traveling crane are likewise reduced.

The arrangement is such that, without moving from the front of the gage board, one man can, single handed, put two engines on the furnace very quickly. The operations are stated as follows: open cold blast valve, (operated by compressed air, controlled from in front of the gage board) to proper furnace, thus letting the blast pressure directly upon the Dyblie automatic check valve on top of the tub; second, by same means, open air snorting valve at side of tub; third, open jacket water valve; fourth, throw in igniter switch; fifth, open gas throttle; sixth, open valve supplying compressed air for starting gas engine. The engine will immediately pick up speed and run under the control of the governor, the tub discharging its air through the snorter out of doors, the Dyblie valve remaining seated under the blast pressure; then, seventh, by means of compressed air, close the snorting valve and the Dyblie valve automatically opens wide and the engine is blowing the furnace. The engine being at all times under the control of the governor, its speed does not vary when it is put on the furnace. It can be put on a furnace very rapidly, always in less than one minute, and the author states that he has seen it done in 35 seconds, with the engine absolutely cold.

It is highly important that the air should be measured into the furnace as carefully and as uniformly as the ore, coke and limestone. A good modern blowing tub with automatic valves is the best known means of measuring air outside a holder. With properly designed air valves, leakage is infrequent, but if there is leakage, it can be easily detected and remedied. The weight of the air delivered to the furnace per minute must remain constant no matter what the variation in the blast pressure. This requires that the engine have tubs designed with the utmost care and that it be equipped with very sensitive speed governors. Sensitive recording speed charts are also installed.

One of the novelties in the design of the plant is that, contrary to the usual practice, the Theisen gas washers have been located directly in the engine room, the idea being that since economical operation of the gas engine is dependent upon the cleanliness of the gas, the chief engineer of the power house ought to be directly in charge of the gas-cleaning apparatus. This arrangement has proved very successful at the Maryland plant. It required only the addition of one bay to the length of the station and saved nearly the whole first cost of the Theisen washers, with its traveling crane, etc. (9 pp., 7 figs. l)

The Burden Water-Wheel, F. R. I. Sweeney

PEARL HARBOR DRY DOCK, H. R. Stanford.

The paper describes in considerable detail the construction of the Pearl Harbor dry docks. Among other things,

the author discusses the concrete used in that construction and describes tests made on them. Only this part of the paper is here abstracted.

Numerous experiments were made to determine the mixture which would produce the most dense and plastic concrete. The ingredients in each mixing were carefully weighed, then mixed with shovels and placed in an 8-in. pipe closed at one end, to determine the volume of the mixture. The degree of density was obtained by comparing the volume with the weight. The plasticity was determined by observing the action of the concrete when handled with shovels and by the settlement into the mass of two wooden rods having sectional areas of 1 and $2\frac{1}{2}$ sq. in. respectively, under the weight of a man.

It was found that, other conditions being the same, the concrete made with the 1 in. stone was more dense and plastic than that obtained with the larger stone. Graded stone, containing such percentages of each size that when

IV	sand from Puget Sound.			

plotted it gave a straight line, produced concrete which was at the same time most dense and plastic. An excess in the percentage of small pieces increased the plasticity but decreased the density, whereas a deficiency in the smaller sizes had little effect on the density but reduced the plasticity. Mixtures in proportion of 1:2.5:4 were more plastic than 1:2:4 but not as dense; 1:2:4 mixtures were more dense than those of 1:2:3.5 but not as plastic.

A series of 132 laboratory crushing tests were made on 6 in. tubes. Nine sets of 12 blocks were made of concrete mixed in proportions of 1:2:3.5, using for each test uniformly graded stones not larger than 1 in. but with differently mixed or prepared sands for the different tests. The results are given in Table 4.

In addition to that, fifteen large-sized test blocks were made under conditions which resembled those actually existing when placing under-water concrete for the bottom of the dock. The concrete for these tests was deposited with tremies in water about 52 ft. deep, the end of the tremie being held near one corner of the form, so that the concrete had to flow an extreme distance of about 6 ft. after leaving the tremie.

A great deal of interesting experience in the use of tremies has been acquired in handling a product at first practically

worthless, and then gradually improved until it finally attained a high degree of excellence. Tremies 12 in., 15 in. and 18 in. in diameter were used in these experiments (approximately 14,840 cu. yd. of concrete were deposited through tremies), and the author arrived at the following conclusions:

The results obtained from a tremie depend to a great extent on the proportions, character of materials and plasticity of the concrete which is being used; the excessive frictional resistance to the movement of concrete in a 12 in. pipe causes frequent clogging in the pipe and gradually increases the pressure at the exit, making it impracticable to hold the end of the tremie embedded in the deposited concrete; the frictional resistance to the movement of concrete in an 18 in. pipe is not sufficient to prevent the occasional loss of a charge in the tremie, thereby interrupting the filling of the form, with added uncertainty as to the quality of the product; the frictional resistance in a 15 in. tremie is apparently just about right to obtain the proper discharge pressure necessary for efficiently regulating the flow of concrete by raising and lowering the tremie with the end maintained within the deposited mass. The concrete flows freely to distant parts of the form without causing disturbance in the mass. The tremie 15 in. in diameter is best suited for the work, and in the Pearl Harbor dry dock construction the size was adopted and actually used for placing the greater part of the tremie concrete.

Approved designs, however, eliminated practically all tremie-placed concrete, without involving endangering conditions. This fact is considered a most valuable feature of the plan of construction, inasmuch as there can be no absolute certainty that concrete deposited under water will possess the uniform degree of perfection essential to dock construction. 72 pp., 19 figs. and 25 plates, *de.*)

CLEVELAND ENGINEERING SOCIETY

Aerodynamics—Development of Mechanical Flight, H. C. Gammeter

Some Machine-Tool Developments of 1914, L. P. Alford (abstracted)

SOME MACHINE-TOOL DEVELOPMENTS OF 1914, L. P. Alford

The paper presents a very interesting record of the development of machine shop equipment during 1914, from information previously published in *The American Machinist*, of which the author is the editor. The paper cannot be fully abstracted owing to lack of space, and only the most prominent sections are here reported.

One of the questions which the author takes up is whether new machines should be introduced in dull times. On the one hand, there is the desire to stimulate business by offering something new, and the desire to use shop effort, released from the strain of regular production, in developing new ideas. On the other hand, however, the machine tool business is so firmly established on sound engineering principles and firm industrial bases that there is only a very remote possibility that any builder can endanger his competitor's business through the discovery and control of some startling or revolutionary innovation. No manufacturer need fear for his stock because of the new designs of his competitors, but in the introduction of a new design by the manufacturer himself, there is a possibility of dangerous reaction on his own stock in that he can seriously destroy its salability by

bringing out such improvements. In other words, a manufacturer can easily become his own worst competitor. The conclusion is, therefore, that improvements should be brought out when stock is low and that means, in boom times. As one of the speakers (H. M. Lucas) stated in the discussion which followed, "It is well to work out new designs during the dull times, but do not announce them until you get your old stock all sold. Manufacturers usually announce their new designs too soon."

The question of high speed drilling is discussed in detail. Last year, some sensitive drilling machines were put on the market, having spindle speeds as high as 10,000 r.p.m., although experimentally, drilling has been done with speeds up to 20,000 r.p.m. In the larger sizes of machines, 1 in. drills have been successfully run on tests at a speed of 12,000 r.p.m. and a feed of 1 in. per second in cast iron. (The author has seen these tests.)

In high speed drilling with numbered sizes of drills it has been found that the limit of the rate of speed is the muscular activity of the operator. Once the drill has entered, it can be pushed through as rapidly as the operator chooses to move his arm. The tendency of power feeds is toward still higher speeds for small drills than can be obtained by hand, and while the limit of speed has been frequently reached with sewing and shoemaking machines, due to lack of quickness in the operator, with machine tools the operator has always been able to keep up easily with the machine. It appears reasonable, therefore, to expect that the commonly used speeds for drilling and feeds of small drills will be greatly increased within the next few years.

The author discusses in detail the possible limitations in drilling practice. Of these, it appears that the wear of the drill is little affected, in the end, by the speed. The cutting edges of the drill are rather preserved than otherwise, at the higher speeds. As regards heating effects, it is claimed that the total heating effect at high speed is less destructive to drills than at slower speeds. The stresses on the drills are less, the drill is advancing rapidly into the cold metal and as the period of drilling an individual hole is short, the proportion of time that the drill is in the air to the time that it is cutting is increased. It appears, also, that at high speed drilling, less heat will be given to the tool by the chips than at low speed drilling. This is due to a hitherto unexplained fact, namely, that when the chips break off, they are cold and uncolored, but become hot and colored a few seconds later. This action has also been observed in milling and turning.

Increased speed of drilling makes it more important than ever that jigs and work-holding devices should be so designed that they can be rapidly operated. This may mean the use of cams, eccentrics or levers, which are more quickly locked and unlocked than strap and screw-operated devices. Further, increased production means an increase in the rapidity with which chips are produced and jigs must be so made that the chips can be easily brushed or washed away.

The year 1914 has seen the introduction of a system of applying a large amount of lubricant to milling cutters mounted in a rigid machine, whereby peripheral cutting speeds on mild steel ten to twelve times greater than accepted practice (800 ft. per min.) were attained in tests of long duration, with a possible increase in the amount of feed from 30 to 112 in. per min. This system, because of the

large amount of lubrication used, has become known as "stream lubrication." Its use is based upon the fact that the heating of the cutter is often the *limitation* to speed, and this can be reduced by using a lubricant or coolant sufficient to remove the heat and keep the cutter and the work cool.

One of the advantages of high speed milling is that it brings the revolution marks closer together, and it is claimed that miller outputs are controlled to-day, in perhaps 90 per cent of cases, by the distance between the revolution marks.

The past year has also played an important part in the development of the so-called "station type" machine, which means a machine in which there is a position for putting in and taking out work and other positions for performing successive operations. While as a tool, it is not new and many machines of this type have been built for special jobs, it was only in 1914 that these machines were brought out for the market in a form to be used on many jobs adapted for a wide variety of work. The needs of the automobile industry have been a feature in developing this line. They have been designed to fulfil the demand for quantity machinery manufacture with unskilled workmen and to make possible an increase of production with a decrease in the accompanying overhead expense.

The main trends of machine tool development in 1914 are summarized by the author as follows: They are toward the use of higher speeds, finer unit feeds, and greater quantities of lubricants; the further development of jigs, fixtures and holding devices which may be operated in a minimum time and the use of highly organized automatic machines, performing a number of successive operations, and suitable to be attended by unskilled labor. Consideration with Regard to the Rapid Transit Problem in Cities, George F. Swain

The Electric Furnace for Re-Heating, Heat Treating and Annealing, T. F. Baily (abstracted)

THE ELECTRIC FURNACE FOR RE-HEATING, HEAT TREATING AND ANNEALING, T. F. BAILY

The paper discusses the use of electric furnaces for re-heating, heat treating and annealing, both historically and practically.

The type of furnace apparently best adapted for re-heating operations is the resistance type in which the material to be heated is entirely separate from and independent of the resistance element in which the heat is generated by the electric current, making it extremely simple and convenient to operate. In some heating operations, the actual cost of heating per ton is less with the electric furnace than with combustion furnaces, while in some heat treating and annealing operations, the precision with which the operations are carried out must be the justification for the higher cost of heating in the electric furnaces. In a general way, it is stated that the higher the temperature at which the heating operation is conducted, the higher the relative economy in the use of electric furnaces. The author sums up the principal advantages of electric furnaces for reheating, as follows: More accurate temperature control; non-oxidizing atmosphere; saving in space; elimination of blast and stack; evenness of temperature throughout the heating space; simplicity of control; smaller amount of heat lost to the sur-

rounding atmosphere; and cleanliness of surroundings. The smaller amount of heat lost to the surrounding atmosphere makes the work around an electric furnace, especially in summer months, far more healthy and agreeable than with the combustion furnace.

The thermal efficiency of electric furnaces vary with the size and capacity in tons per hour, a furnace of 1 ton per hour of 2200 deg. showing an efficiency of 75 per cent. Most of the terminal troubles in electric furnaces for reheating have been practically entirely eliminated; for example, one set of electrodes now lasts for months at a time in continuous service. For furnace temperatures not exceeding 2500 deg. Fahr., the electric furnace will answer any reasonable requirements, and, so far as actual fuel cost alone is concerned, at one cent per kw-hr., will compare favorably with oil furnaces burning oil at four cents per gallon.

In large tonnages of heavy billets, the combination of a combustion furnace using producer gas up to 1500 deg. Fahr., and heating by electricity from this temperature to the desired rolling temperature offers the advantages of low fuel costs per ton of metal heated and a minimum amount of oxidation of the metal, beside protecting the electrodes. Such a furnace can be expected to show a thermal efficiency in the gas end of 50 per cent, and in the electric end of 75 per cent.

The author discusses, in some detail, the use of electric furnaces for soaking pit and for heat treating and annealing purposes. The type of furnace best adapted to heat treating is the automatic continuous furnace, where the metal under treatment when fired to the predetermined temperature is automatically discharged into the air or into some quenching medium. When the material at the discharge end of the furnace reaches the minimum temperature, a special pyrometer closes an electric circuit, which in turn closes, through a suitable relay, the solenoid-operated radial dial switch, and the various electrical circuits operate, in proper sequence, the doors, pusher and quenching apparatus.

In regard to the economy of small electric reheating furnaces from the fuel point of view alone, where the current consumption per ton is 480 kw. and the rate is one cent per kw-hr., they can be compared with oil where the consumption per ton is 100 gal. at four cents per gallon, or natural gas where the consumption per ton is 12,000 cu. ft. Electric furnaces of the continuous type, of 5 tons per hour capacity, will show a commercial economy over coal fired furnaces of the same capacity with coal at \$2 per ton (requiring 200 lb. of coal per ton of steel), while electric furnaces require an electric current consumption of 250 kw-hr. per ton with current at one-half a cent per kw-hr. The combined gas and electric furnace will show a commercial economy, compared with producer gas fired furnace using 200 lb. of \$2 per ton coal, while the combination gas and electric furnace uses 140 lb. of coal per ton of metal for heating it to 1400 deg. (30 pp., pd).

High Temperature Investigation and a Study of Metallic Conduction, Edwin F. Northrup

Sound Steel for Rails and Structural Purposes, Sir Robert A. Hadfield

A Study of Some Curious Painting Phenomena, Henry A. Gardner (abstracted)

An Air Analyser for Determining the Fineness of Portland Cement (U. S. Bureau of Standards)

A STUDY OF SOME CURIOUS PAINTING PHENOMENA, Henry A. Gardner

This paper includes an investigation of the destruction of paint, especially on buildings, by fungus growths.

The writer noticed that certain types of paint were affected by what is called mildew by painters; not everywhere, but more severely in sections which were shaded by trees or in partially sheltered nooks where dampness would be maintained for considerable periods of time.

Sections of painted surfaces showing marked formation of mildew were collected: In some instances, the mildewed surfaces were lightly scraped with a clean knife and the scrapings collected in a special envelope. A culture medium was then prepared which would exert an inhibitory action upon any ordinary bacteria which might be present upon the specimens, but which would permit the rapid propagation of the fungus spores.

As cypress is one of the most important woods used for construction purposes, especially in the South, where the investigation was carried on, a cypress decoction was prepared in the following manner: 50 grams of finely divided wood shavings were boiled in a half liter of distilled water. The decoction was filtered and $\frac{1}{2}$ per cent of thread agar was added. After steaming to obtain solution, the mass was filtered, tubed and sterilized at 120 deg. cent. for 15 minutes.

The two principal types of fungi which were developed from the mildewed surfaces were shown to be species of *Aspergillus* and *Penicillium*. Tests have shown that black *Aspergillus* proved the more hardy, while others seemed dormant unless kept constantly moistened. In one test, the black mould, in a week's period, exerted a most destructive effect upon a board coated in white lead with oil, the oil apparently serving as a most favorable medium for this development, and thus playing a leading part in the reaction which results in the destruction of the paint and the exposure of the wood. The development of fungi in every instance was much more rapid upon paint coatings which were soft and subject to retention of moisture, while paints which presented a firm, hard, moisture-shedding surface resisted the fungi and prevented germination of the spores.

The author comes to the conclusion that micro-organisms may play an important role in the behavior of materials of paint, as shown by recent investigations into the causes of certain paint troubles referred to by painters as saponification or washing. This condition is generally indicated by the appearance of a white deposit at the base of porch columns and by the paint assuming a soap-like condition when rubbed. While instances of such action are rare, there was recently an apparent epidemic in one community. The author collected samples of the washed paint for analysis, as well as making analyses of the oil that was mixed with the paint paste by hand. The oil almost invariably was found to contain considerable moisture, as well as a large percentage of mucilaginous or albuminous matter, which is commonly called "foots." Portions of the "foots" from the various samples of oil collected were placed upon sterile agar, and in a few days marked growths of pink colored mould were obtained, identified later as a specie of *Fusarium*. Portions of this mould placed upon oil seemed to produce free acid, which explains the washing of paint in which the

infected oil was used. The enzymes and micro-organisms in the "foots" apparently exerted a fat-splitting action, the oil being broken up into glycerine and fatty acids, causing the formation of soap-like products which are acted upon by moisture, in addition to which the glycerine formed in the film serves to keep the paint soft and tacky, readily attracting moisture from the air. The moisture in its turn emulsifies with the soft paint, some of which washes off.

The washing of paint is not of uniform occurrence. It may be noticed upon the porch columns, but not in the body or trim of a house, and only upon certain sections of the main structure. The writer has observed that in most instances where washing has shown itself, it has generally been on a hollow column or a surface the back of which may hold moisture. It is likely that the moisture stored up in certain places is responsible for starting this reaction.

The so-called "rust" or brown spotting of paints may be traced, in some cases, to the action of soluble matter contained in the wood exuding at certain places in the paint film and drying up into small, hard globules. It may also be due to the nature of the oil if it contains moisture and "foots" of an infected nature. In such cases, the hydrolizing action of the enzymes apparently increases the tendency of the oil to break up into various fatty acids, including formic acid. This has a solvent effect upon the lead and zinc pigments, producing lead and zinc formates which are soluble in water.

From the above, it is apparent that the selection of a satisfactory oil is of very important consideration, especially upon repainting work. Immunization of oils is best done by the application of heat, which is not, however, directly feasible in some cases. On the other hand, mixtures of oil and pigments are often run through Babrstone mills at temperatures up to 240 deg. Fahr. (depending upon the rate of grinding and set of plates), which is more than sufficient for sterilization.

Tests by the author have shown that paint is in a most satisfactory condition after storage if the hot paste was allowed to cool before thinning and canning. When, however, paste paints are thinned by the painter, only clarified, well settled, moisture-free linseed oil should be used (15 pp., 15 fig. *epd*).

INSTITUTION OF MECHANICAL ENGINEERS

Advance paper B, read May 14, 1915, London.

THE DISTRIBUTION OF HEAT IN THE CYLINDER OF A GAS ENGINE, Professor A. H. GIBSON and W. J. WALKER

The paper presents data of tests having for their purpose the determination of how the distribution of heat throughout a gas engine varies with the speed of the engine, b.h.p., and the compression ratio, and richness of the air + gas mixture.

Tests were carried out on an experimental gas engine recently installed in the engineering laboratories at University College, Dundee. This engine, with a cylinder diameter of 11 in. and a stroke of 19 in., afforded exceptional facilities for such investigations. The connecting rod could be lengthened so as to vary the compression ratio between the limits of 5.17 and 6.62. The cylinder jackets were divided into two parts, one of which surrounded the exhaust valve and the portion of the exhaust passage included within the cylinder casing, while the other covered the breech end and barrel of

the cylinder. The jacket water was led in series through the two sections, the temperature being measured before and after passing through each of these. This made it possible to ascertain, with a higher degree of accuracy than usual, the heat lost to the jacket apart from that portion of it which correctly should be attributed to exhaust losses.

The normal speed of the engine was 200 r.p.m., but in the trials a range of speeds from 140 to 260 r.p.m. was examined. The b.h.p. was varied from zero up to full load capacity. Three different compression ratios and three different air-gas mixtures were used. In all, 130 trials were carried out, the details of which are described in the paper. In the main it was found that:

The *mechanical efficiency* of the engine increased with increase in loads; diminished as the ratio of air to gas increased; diminished as the speed increased and was sensibly independent of the compression ratio; the maximum efficiency attained in these trials at full load with the richest (7:1) mixture, and at the lowest speed (150 r.p.m.) was 88 per cent.

The *thermal efficiency* as measured on i.h.p. increased with the load; attained the maximum with an air-gas mixture of approximately 10 to 1; increased very slightly as the speed increased and increased as the compression ratio increased.

Thermal efficiency on b.h.p. increased with the load; attained a maximum with an air-gas ratio of 8 to 1, that is, with a richer mixture than gave maximum i.h.p. efficiency; diminished as the speed increased and increased with the compression ratio.

The *ratio of the actual thermal efficiency* measured on the i.h.p. to the corresponding air cycle efficiency increased with the load; had maximum value when the ratio of air to gas was approximately 10 to 1; increased slightly with the speed and was sensibly independent of the compression ratio. At full load and with the most efficient air-gas mixture, the relative efficiencies were for all compressions from 0.687 at 150 r.p.m. to 0.709 at 250 r.p.m.

The percentage *exhaust losses* diminished as the load increased; diminished very slightly as the ratio of air to gas increased; increased as the speed increased and diminished as the compression ratio increased.

Jacket losses. The percentage heat carried away by the water flowing through the cylinder jackets, not including the exhaust valve jacket, increased with the load; diminished as the speed increased and was sensibly independent of the compression ratio. Various facts indicated that the rate of transmission of heat through cooling surfaces was much greater at the higher speed in spite of a lower gas temperature. This was apparently due to the fact that the greater turbulence of the working fluid at the higher rates of speed increased its effective conductivity to an extent which more than counterbalances the effects of a smaller temperature difference and a shortened time of contact. Other things being equal, a 6 per cent increase in the temperature of the gases would probably increase the heat transmitted by conduction and radiation by some 15 per cent, so that it might be taken approximately that the effective conductivity was increased in the same ratio as the speed of the engine.

The radiation loss diminished as the load increased; increased as the ratio of air to gas increased; diminished as the speed increased and increased slightly as the compression ratio increased. (23 pp., 6 figs. c.)

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS

No. 55, London.

TELEGRAPH TRAFFIC AND POWER PLANT FOR PNEUMATIC TUBES IN POST OFFICES, Alec B. Eason

The information in the paper was collected in order to form estimates of the cost of pneumatic installations and current for working various tubes. The problem of determining the probable traffic which the tube will carry under certain conditions, and especially the hourly maximum carrying traffic, is discussed. From this, the writer proceeds to the question of the quantity of air which will be needed to drive the carriers through the proposed tubes; and finally, the size, type and kind of pump which will be most efficient for the work and the probable over-all efficiency of the motor and pump. Only electrically driven sets are considered, these being, in the estimation of the author, the type used almost exclusively in modern installations wherever possible. Only the second and third sections of the paper (Air Required in Installations, and Pumps and Motors), are abstracted here.

In regard to air used per carrier in street tubes, the writer points out that when sending with pressure, the amount of air used for any practical container pressure may vary greatly, according to the types of cocks which are used and the amount of throttling in the circuits. The author describes a series of tests made to determine the amount of air and gives the following formula for the quantity of air used in tubes working intermittently:

$$Q = \frac{V}{13.08} \frac{p' - p''}{14.7}$$

where Q = pounds of air; V = the container volume in cubic feet; 13.08 = cu. ft. of air in 1 lb. at 60 deg. Fahr.; and $p' - p''$ = drop in the container pressure in pounds per square inch, the temperature of the container being assumed to be constant during the time of the test.

In regard to vacuum working, it appears that with the same vacuum in the container, approximately the same amount of air, 7 lb., is used no matter what the throttling may be. The practical importance of this fact is that with intermittently worked tubes, used in an upward direction, one can introduce full bore services and get increased speed without increased consumption of air. The usual objection as to lax attendance applies to any kind of service, and although increased loss may occur when working with full bore cock, at increased speed, the amount of the increase is small and may easily be overbalanced by saving in the loss due to leakage in the three-way cocks, as the author shows by a calculation.

As regards working with different container pressures, it has been found that with a 5 lb. container pressure and full bore cock, the total time is 55 seconds as against a transit time of 53 seconds when using a container pressure of 8 lb. and the cock at half position: the consumption of air at the lower container pressure was five-sixths of that at 8 lb. pressure. It is best, therefore, to get rid of throttling and use lower container pressures.

Tests at Hull, made in 1911, have shown that the increased

speed with high vacuum was obtained without any increase in air consumption, but it should be noted that the energy consumption is increased because the air is taken to a higher vacuum.

A series of tests were made on house tubes, i.e., those which lay wholly within one building. The author found that for house tube work, it would be necessary to allow a consumption of air of from $1\frac{1}{4}$ to twice the volume of the tube. If the speed is high, the consumption will rise to 2 or $2\frac{1}{2}$ times the volume of the tube. The loss due to differences in turning off the cocks promptly is relatively great, as the transit time of carriers is only 5 to 10 seconds.

The leakage of pneumatic tube systems may be divided into three kinds: *a* leakage from the container, pipe-work, and cocks; *b* leakage from the D boxes, double slide switches and fittings, and *c* leakage from the tubes. Leakage *a* occurs in the building, is easily noticeable and therefore should not exist to any great extent. Leakage *b* always exists, but varies in extent with the age and wear of the sliding portion of the fittings. Leakage *c* should not be allowed to any great extent, but it is difficult to locate the position of the leaks in street tubes and repairs to them are costly. Leaks are sometimes allowed to continue, therefore, as long as they do not affect the working of the tube too much. Leakage *a*, at Brighton, amounted to about 68 lb. of air per day, the total amount being 300 lb. The leakage at Hull, on a vacuum container, caused a rise of 2 lb. in $3\frac{1}{2}$ minutes, equivalent to about one-fifth of a pound per minute extra work. For leakage *c*, on London tubes the following amounts (including leakage *b* in some cases) were found: For individual tubes, .22, .30, .47, .37, .60, 5.4 lb. of air per minute. The total leakage for nine tubes working on pressure was 4.7 lb. and for twenty tubes worked on vacuum, 3.5 lb. The total *b* and *c* leakage in London is about 900 lb. per hour, or something like 5 per cent of the total load.

The author considers in detail the various types and dimensions of carriers, and comes to the conclusion that carriers should fulfill four requirements: *First*, large capacity; *second*, retentivity, which means that messages should not drop out of them; *third*, durability, and *fourth*, ease of manufacture. Metal carriers, to be satisfactory, must have buffers or felt skirts at both ends.

The author likewise discusses the various systems of working pneumatic tubes, such as the Dudley system installed when the tubes are short enough, and the high pressure system, with which a saving occurred when the ratio of the maximum load to the average was large. Tests with high pressure systems have shown that it was not worth while pumping air to high pressures. The usual limits were from 10 to 50 lb. per sq. in. and the investigation showed that the higher the pressure, the greater the total energy consumption, including the light load loss, for the whole day.

A careful investigation was made to determine the size of pumps required to deal with air under various conditions of pressure and vacuum as well as the size of motors needed to drive these pumps. The author derives a formula showing the rising pressure in the time t , when the speed of the pump is supposed to be constant. He also discusses the question of volumetric efficiency of the pump. The results of the tests at Hull, Brighton and Sheffield show discrepancies when compared with the usual theory. In general, the author arrives at the following conclusions:

The input to motors driving air compressors is 1.6 to two

times the work required to compress the amount of air dealt with isothermally between the working pressures (from tests, it has been found that working with pressure accurate figures for either volumetric efficiency or over-all efficiency cannot be obtained by noting the rise of pressure in closed containers). The maximum horse power input to motors driving vacuum pumps delivering it to the atmosphere, is $1/25$ of the displacement in cubic feet per minute. (104 pp., 11 figs. *et.*)

A Bolometric Method of Determining the Efficiencies of Radiating Bodies, William H. Bone, H. L. Callendar, H. James Yates.

The Elastic Properties of Steel at Moderately High Temperatures, F. E. Rowett (abstracted).

THE ELASTIC PROPERTIES OF STEEL AT MODERATELY HIGH TEMPERATURES, F. R. Rowett

In a previous paper the author gave results of measurements of elastic hysteresis of steel tubes when subjected, at ordinary room temperature, to torsional stresses within what is ordinarily regarded as the elastic limit. In the present research, an attempt was made to establish the difference in the behavior under stresses at higher temperatures of both hard-drawn tubes and annealed tubes.

It was expected that the former, containing a good deal of amorphous material, would begin to behave like a viscous fluid,—that is, it would flow, more or less freely, under stress, whereas at the same temperature, the annealed tube being crystalline, though it might take a permanent set, could not flow or would flow to a much lesser degree, on account of the small amount of amorphous material in it.

It was found, actually, that at a temperature of 300 deg. cent., hard and annealed tubes began to show properties similar to those of pitch at ordinary temperature, or of glass at a temperature rather below the softening point. They were still highly elastic under varying stresses, but flowed perceptibly when the stress was applied for a great length of time, the energy dissipated in a cycle of stress depending upon the speed of the cycle. If the cycle was performed in five seconds, the area of the closed stress-strain loop was not much greater than at ordinary temperature and was less than that given by an annealed tube, but if the cycle took a quarter of an hour, the dissipation was increased four-fold.

In the annealed tube, however, at 300 deg. cent., the energy lost per cycle of stress was still almost independent of the time. At a higher temperature—for example, at 540 deg. cent.—the hard drawn tube flowed rapidly and continued to flow for a long period, though at a diminishing rate under a shear stress of less than one ton per square inch. At this temperature, steel, like pitch or glass, showed considerable after-working. Some flow and elastic after-working were also observed in the annealed tube at this temperature, but both of these tendencies were much less than in the hard.

The steel tubes had the following chemical composition: Carbon, 0.17 per cent; manganese, 0.24 per cent; sulphur, 0.02 per cent; phosphorus, a trace.

The elastic limit in torsion of the tubes as supplied by the makers was 13.8 tons per sq. in. shear stress in either direction, giving an elastic range of 27.6 tons per sq. in.

The data of tests are presented in the original article in the form of tables and curves. (13 pp., 4 figs.)

ROYAL SOCIETY OF ARTS

Journal, vol. 63, Nos. 3259 and 3260, May 7 and 14, 1915, London

(No. 3259) On the Measurement of the Efficiency of Domestic Fires, and on a Simple and Smokeless Grate, A. V. Harecourt (abstracted)

(No. 3260) Recent Progress in Pyrometry, Chas. R. Darling
ON THE MEASUREMENT OF THE EFFICIENCY OF DOMESTIC FIRES, AND ON A SIMPLE AND SMOKELESS GRATE,
A. V. Harecourt

The writing of the present paper was prompted by a desire to determine whether a sprinkling of a solution of a powder in water, consisting mainly of common salt, on lump coal, burned on a domestic grate, increases the efficiency of the fire. Theoretically, this did not seem likely, but the

FIG. 7. "Radio" THERMOMETER FOR MEASURING RADIANT HEAT

writer wanted to establish definitely what actually would happen.

To do this, he found it necessary to measure the amount of heat radiated into a room, which led to the development of the instrument illustrated in Fig. 7, which the author calls a radio-thermometer, i. e., a measurer of radiant heat. It consists of a copper box 6 x 6 x 1 in., with a small funnel-shaped inlet, enclosed in a wooden box 7 x 7 x 2 in., open at the top and with an opening 5 in. square in the middle of one side. Except on this side, there is a space between the two boxes, of an inch at the back and $1\frac{1}{2}$ in. at the sides and below, loosely packed with cotton-wool. On the side which is in contact with the wood, the central 25 sq. in. are exposed and blackened. A thermometer, used also as a stirrer, is held by a cork in the opening at the top. It is furnished with a cup-shaped piece of sheet rubber tied on above the bulb, stretching across the box. The weight of the copper box is 11 oz.; that of the water which fills it, is 1 lb. 6 oz. The water-equivalent of the copper box is $11 \times 0.095 = 1.045$ oz.; hence the mass of water heated may be taken as 1 lb. 7.04 oz., or 1.44 lb.

The instrument having been freshly filled with cold water is placed facing the middle of the fire at a distance of 3 ft. Exactly on the minute by the watch, the thermometer is

read; about 9 min. later the water is briskly stirred up and down with the thermometer, which is then replaced with its bulb central, and at the end of 10 minutes, the thermometer is again read. These readings are repeated every 10 minutes until the temperature of the water is as much above the temperature of the air taken by a thermometer at the back of the instrument as it was below it at the start. The cotton-wool, which checks the flow of air around the box, prevents the temperature of the air in the room having too much influence, and both this and the exchange of radiation are approximately balanced by the temperature of the water, being to an equal extent and for nearly the same time, first lower and then higher than that of its surroundings.

To make the results, with the fire larger and smaller at different times, more nearly comparable, an estimate was made every ten minutes of the area of fire, from which the chief part of the heat was being radiated (this area is expressed in "spaces"). A large number of measurements have been made of heat radiated from coal, from coke, from coke which had been wetted and from coal and coke treated with a salt solution. The average results in units of the method are as follows: coke, 1.97; coal, 1.63; wet coke, 1.29; coke and coal sprinkled with water and powder, 2.03 (the presence or absence of the powder made no practical difference).

These results seemed to be probable. Coal, when it burns, passes through two distinct stages; first, it gives off gas, some of which is burned and some of which escapes unburned. When evolution of gas has ceased, the coal has been changed to coke and the second stage begins, when it burns with a steady glow. During the first stage, much less heat is radiated than during the second, as the heat from the burning gases goes chiefly up the chimney. Wet coke, if sufficiently wet, gives still less heat at any moment, for it burns more slowly and some of its heat goes to evaporate the water.

From this, the author proceeds to the description of a special grate for use in domestic fires. He establishes a number of principles which should be observed in the construction of a domestic fire grate and points out that in addition to purely technical requirements, the grate must not be less attractive in appearance than other grates. He shows, however, several quite attractive illustrations of his design. (9 pp., 7 figs. *gpd.*)

WESTERN CANADA RAILWAY CLUB

Proceedings, vol. 7, no. 8, March 1915, Winnipeg.

THE HANDLING OF FUEL OIL IN EXTREME CLIMATIC CONDITIONS. Lorimer.

The paper discusses the use of oil fuel generally, and in very cold regions in particular, and described the design of special tank cars and storage tanks.

The ordinary tank car is usually of too small a capacity, say 8,000 U. S. gal., which means transportation of a comparatively heavy dead load for a small quantity of fuel. Also its design is not convenient; for example, it has the valve located about 2 ft. off the center line, hence, in making up the train, the cars have to all be headed the same way, which, in railway practice, is almost impossible. Then it has a small opening in the dome which is generally closed

by a round cover provided with a thread, a very objectionable arrangement, especially in very cold weather. Such tank cars are not provided with steam heating pipes and, with an outlet of only 4 in. exposed to the cold weather, it takes a long time to empty the car and, further, it is almost impossible to empty it completely because of the bottom of the car being level. As much as several hundred gallons may remain in the car, and thus not only reduce its effective capacity but remain to be carried back and forth on the line.

To obviate all these objections, a new tank car has been designed with a capacity of 10,000 Imperial gal. It has a dome provided with an opening of 18 in. x 36 in., the cover being hinged and hermetically sealed by means of eye bolts and hand nuts (this makes opening easy in any kind of weather). To make the spotting of the car easy, it has been provided with an outlet valve exactly in the center, and the steam inlets for heating the car are also placed exactly on center, one on each side of the car, so that the car can be headed either way. For purposes of heating, the car is provided with the piping so arranged that the steam starting from the center will travel at once toward the two ends and then come back to the center around the outlet valve which is in its turn provided with a steam jacket, the water of condensation being discharged through a Sareco valve of ample capacity.

For rapidly and completely emptying the car tank, there is provided a trough running longitudinally between the bolsters. This trough is 8 in. wide and riveted to the bottom of the tank is a semi-cylindrical bottom with a depth of 6 in. at the outside extremity and 1 ft. in the center. The outlet valve is riveted to this trough. Six 6 in. and one 6 in. x 18 in. hole in the center let the oil run through the whole length of the car into the trough. The return steam pipe is placed in the bottom of this trough and is connected to the steam jacket of the outlet valve. This permits the oil to be heated thoroughly and run quickly, while the 6 in. fall of the trough towards the outlet valve allows the car to be completely emptied.

The body of the car is composed of a center sill and two body bolsters, resting on the trucks. The center sill, 37 ft. 3 in. in length over striking plates, or 39 ft. c. to c. of couplings, is made of two 12 in. 40 lb. ship-building channels (Carnegie Section) spaced 127½ in. back to back. The two ends up to the bolsters are covered top and bottom by ½-in. cover plates, and between the bolsters, the bottom flanges of the channels are strongly latticed together, and the top flanges are reinforced by two 8 x 3½ x ½ in. angles.

The saving of weight due to this kind of design is about 3,500 lb. per car, the approximate weight of an ordinary tank car of the same capacity being about 44,000 lb. (24 pp., *gpd.*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

MEETINGS

WORCESTER, APRIL 8

At a meeting of the Worcester Section of the Society on April 8, the following committee was appointed: Paul B. Morgan, chairman; Carl F. Dietz, H. P. Fairfield, F. W. Parks and E. H. Reed, secretary.

ST. LOUIS, MAY 19

A meeting of the St. Louis Section was held at Washington University on May 19 and was presided over by Mr. J. W. Woermann, President of the St. Louis Engineers' Club. There was no single paper as such, but a general discussion took place covering the requirements and length of an engineering course of study. Professors A. S. Langsdorf, J. L. Van Ornum, E. L. Ohle, G. O. James, of Washington University; and Professor E. L. McCausland, of the University of Missouri, led the discussion. After the discussion, inspection of the laboratory at Washington University was made.

CINCINNATI, MAY 20

At a joint meeting of the Cincinnati Section of the Am.Soc.M.E. and the Engineers' Club of Cincinnati on May 20, Dr. A. O. Zwick gave an illustrated lecture on Egypt, Light of the World, which showed how our modern civilization is based upon the works of the Egyptians. They originated many of the present-day professions, and their knowledge of many branches of science was more highly developed than was found in our civilization 150 years ago. Dr. Zwick also showed how to compute the ages of the great Egyptian monuments and other structures that were erected some 13,000 years ago. Through the key to the Egyptian language (the Rosetta stone), found by an engineer, many valuable works have been translated which reveal that a remarkably high degree of development in culture and science existed in that remote period.

ST. LOUIS, JUNE 9

A joint meeting at the St. Louis Engineers' Club rooms, presided over by Mr. J. T. Garrett, Vice-Chairman of the local section of the American Society of Engineering Contractors, was held on June 9. The paper of the evening was by J. B. Emerson, of the Robert W. Hunt & Company, on "Needed Improvements in Specifications." The main points brought out were: *First*, too many specifications, while calling for specific tests, do not state with what frequency such tests should be applied; in other words, the number of tests per unit, or number of units per test, being entirely omitted. *Second*, the general clause of many specifications conflict with details given later, leading to much ambiguity. *Third*, the working limits of dimensions given should be more clearly defined. A specification without such limits, in the hands of an inexperienced inspector, causes the contractor a great loss, calling for minute measurements which are neither required nor desirable in that class of work. This paper was discussed by H. M. Cryder, Mr. Cramer, and others.

This was followed by an outline of tests being made by the United States Bureau of Standards, on full sized columns, by Dr. R. G. Olhausen. The total attendance was 46.

MINNESOTA, JUNE 11 AND 12

A joint meeting of the Minnesota Section with the Minnesota Section of the A.I.E.E. was held on June 11 and 12 in Duluth. Mr. Ryerson of the Great Northern Power Company gave a paper, illustrated by lantern slides, on the Great Northern's development and business. Mr. Hearing of the Oliver Iron Mining Company gave a moving picture talk on the Iron Ore Industry of Minnesota. The pictures showed all the process in the mining, from the prospecting to the loading of the ore on the boats for shipment.

The second day of the meeting was taken up with excursions, which included various docks and the new plant of the Minnesota Steel Company.

LOS ANGELES, JUNE 15

A joint meeting of the technical societies in Los Angeles was held on June 15. William Mullholland, chief engineer of the Los Angeles water board; James A. B. Sherer, president of Throop College of Technology, and Samuel Storrow, addressed the meeting on The Service of the Technical Man to the Community.

ST. LOUIS, JUNE 16

A joint meeting under the auspices of the A.S.M.E. was held on June 16, at which Edward Flad, Chairman of the local branch of the A.S.M.E., presided. The paper of the evening was by E. R. Fish, secretary of the Heine Boiler Works. His paper was entitled: Boiler Explosions, and What the A.S.M.E. is Doing to Prevent Them. He traced the development of the idea of standard specifications; how the requirements for safety in boilers were first put into concrete form by Thurston; showed how closely the A.S.M.E. Code fulfilled Thurston's outline requirements. He then told of the lack of uniformity of boiler codes among the various states, and the efforts being made by American Boiler Manufacturers Associations to obtain the adoption of the new code, by all of the state legislatures.

The lecture was concluded with illustrations showing boiler explosions and bad conditions due to failure to follow best engineering practice, both in design and operation of boilers.

There was an interesting discussion following the presentation of the paper by Edward Flad, Prof. E. L. Ohle, L. A. Day, Wm. Hoffman, and others.

At the same meeting the report of the joint committee was made, on the proposed water power development through diverting water from the Missouri to the Meramec Rivers. Previously the Missouri State Legislature had reported on this project favorably, estimating a probable development of 200,000 hp. The Engineers' Club report was distinctly unfavorable, showing that the possible horse-power was only 37,000, and the cost of development much more than that estimated by the state legislature.

NECROLOGY

EBENEZER HILL

Ebenezer Hill was born in South Norwalk, Conn., on October 5, 1849. He graduated from Wesleyan University with a degree of B.A. in 1870, and with a degree of M.A. in 1891. From 1870 to 1880 he was engaged, in connection

with others, in the design, construction and installation of steam pumping machinery and steam engines of various types. In 1880, he became the responsible executive head of the Norwalk Iron Works Company, and shaped the business to the manufacture of air compressors and allied machines. He held this position up to the time of his death, which occurred on February 26, 1915.

JOHN PHILIP ZIFF

John Philip Ziff, Jr., was born at West Point, Cal., on March 19, 1888. He attended the California School of Mechanical Arts and the University of California, from which he graduated in May, 1912. After graduation, he worked with Mr. R. F. Chevalier, a consulting engineer, in testing boilers for numerous gas and power plants in and about San Francisco. In December, 1912, he accepted a position with the Ramie Fibre Company of San Francisco as draftsman. After the failure of this company, he accepted a position with the Sutter Basin Company of Sacramento as draftsman of plans for electric pumping machinery for their reclamation project. Having completed their work in May, 1914, he entered the office of the California State Engineer at Sacramento, Cal. Mr. Ziff died at his home in San Francisco, Cal., on May 24, 1915.

BENJAMIN FRANKLIN ISHERWOOD

Benjamin Franklin Isherwood was born in New York on October 6, 1822. He was educated at Albany Academy and afterward served under David Matthews, master mechanic of the Utica and Schenectady Railroad. He was promoted to the civil engineer's office and, on the completion of the road, he went to work on the Croton aqueduct. After this was completed, he worked on the construction of the Erie Railroad under Charles B. Stuart, division engineer, who later became engineer in chief in the navy, and it was through his influence that Mr. Isherwood entered the navy in 1844. Later he was assigned by the U. S. Treasury Department to work on the construction of light houses, and was sent to France to superintend the construction of light house lenses there from his own designs. At the outbreak of the war with Mexico, he served on board the Princeton, the first American screw steam vessel built by Ericsson for the government as an experiment. He was promoted to be chief engineer of the Spilfire, and he took part in every action in which the American fleet was engaged during the war.

His experiments in the expansion of steam on board the U. S. S. Michigan in 1859 almost revolutionized the methods of using steam. He designed the engine of the U. S. cruiser Wampanoag, which was built in 1868 and which was the fastest steamship in the world at that time. She had a speed of seventeen and three fourths knots.

He was chief engineer in the navy from 1861 to 1869, covering the entire period of the Civil War, when more than six hundred steam vessels and three thousand engineers were in the service.

During the years 1870 and 1871, he was stationed at the Mare Island Navy Yard, California. His experiments there with screw propellers are regarded as among the greatest additions to engineering. He was retired as chief engineer with the rank of rear admiral on June 6, 1884. He was the author of many engineering works, some of which have been used widely as text books in technical schools.

Mr. Isherwood died at his home in New York City on June 19, 1915.

PERSONALS

Thomas R. Cook, until recently assistant engineer of motive power, Pennsylvania Lines West, Pittsburgh, Pa., has accepted the position of chief engineer of the Willard Storage Battery Company, Cleveland, Ohio.

Everett W. Swartwout, formerly of the Chicago office of the Nordberg Manufacturing Company of Milwaukee, is now associated with M. N. MacLaren in the New York office of the company.

John E. Lord has accepted a position with the Nordberg Manufacturing Company as manager of their Chicago office. He was until recently with the Buckeye Engine Company.

Myron J. Bigelow, who was connected with the Molyneux Mailing Machines Company of Buffalo, N. Y., has severed his connection with that company and is now consulting engineer, located temporarily in Akron, Ohio.

Gustave R. Taska, consulting engineer, New York, has been appointed lecturer in municipal waste disposal at Columbia University, New York, and will deliver a course of lectures on this subject at the University during the coming year. Mr. Taska has for some years been acting as consulting engineer to various garbage, refuse and waste disposal plants both in this country and abroad.

Ronald C. Hands has become affiliated with the Winchester Repeating Arms Company, New Haven, Conn., as assistant to the supervisor of the mechanical division. He was, until recently, connected with the planning and efficiency work of The Bridgeport Brass Company, Bridgeport, Conn.

David J. Lewis, Jr., has become associated with W. J. Wayte, a chemical engineer, with offices in New York, operating as consulting engineers under the title of W. J. Wayte, Incorporated. Their specialty is the utilization of wastes in power and manufacturing plants, especially in sugar and chemical works.

T. Omdal, formerly mechanical engineer with Lieberman and Sanford Company, New York, is now a member of the firm of The Equity Iron Works, Brooklyn, N. Y.

William E. Choate, acting general manager of the Carr Fastener Company, Cambridge, Mass., will leave that position August 1 to take a similar one with The Advance Machine Company of Boston, Mass.

John E. MacArthur, formerly connected with the Pierce-Arrow Motor Car Company and more recently superintendent of the Keystone Manufacturing Company, resigned on May 1 to become general superintendent of the Robinson Fire Apparatus Manufacturing Company of St. Louis, Mo.

Jacob M. Howarth has become associated with Marshall Field and Company of Chicago, Ill., as assistant chief engineer. He was until recently mechanical draftsman and test engineer in the U. S. Yards of Swift and Company, Chicago, Ill.

Harold K. Beach has been transferred from the Atlanta, Ga., office to the New York office of Lockwood, Greene and Company.

William E. Bullock has resigned his position as assistant to the Secretary of The Franklin Institute and has been appointed on the editorial staff of the Am.Soc.M.E.

George B. Massey has resigned as foreign sales manager of the Bucyrus Company and has formed the Geo. B. Massey Company, consulting engineers, on excavating machinery and methods, with offices in the Peoples Gas Building, Chicago.

Edwin G. Hatch has opened an office for consulting work in the Equitable Building, New York, and will have associated with him Herschel C. Parker, for twenty-one years professor of Physics in Columbia University. Mr. Hatch was formerly associated with Walter G. Clark of New York, specializing in electrical work, having entire charge of the work in New York since 1913, during Mr. Clark's absence in the West. Mr. Hatch was also treasurer and manager of the Clark Electric Company, and was largely instrumental in developing the company's high tension line apparatus.

STUDENT BRANCHES

CARNEGIE INSTITUTE OF TECHNOLOGY

The last meeting of the year held by the Carnegie Institute of Technology was addressed by George H. Redding, assistant secretary of the Institute, on The Success of Mechanical Engineering Graduates of the Carnegie Institute of Technology.

Mr. Redding first told of the method used for keeping statistics of the graduates. Every year a blank is sent to each graduate to be filled out and returned to the Institute. The information asked for included the kind of work being done, the salary being received, and whether the man is satisfied with his work. He is also asked in what range his salary lies. In reply to the last question, the following ranges have been submitted: 900-1200, 1200-1500, 1500-1800, 1800-2000, 2000-2500, and above 2500. This method has proved quite satisfactory, and most of the graduates have responded with the required information. Mr. Redding said that, however unfair it might be to measure a

FIG. 1 CURVES OF SALARIES OF GRADUATES IN MECHANICAL ENGINEERING OF THE CARNEGIE INSTITUTE OF TECHNOLOGY, SCHOOL OF APPLIED SCIENCE

man's success by the salary which he receives, it is their only means of tabulating and representing in graphical form the progress of a large number of men over a period of years, and that the accompanying chart would give young engineers a fair idea of what they might expect when they got out into the world of working men. The data which has been used has included information from approximately ninety per cent of the mechanical engineering graduates. Some men just out of college become, in a short time, dissatisfied with the routine and grind which must always be undergone if success is to come. It is a significant fact, however, that the majority of these mechanical engineers who deviated from engineering work eventually went back to the field for which they were trained. One man, for instance, a graduate of early years, went into another field of work in which he was able to make a very large salary. He is now, however, doing mechanical engineering work whereby he can gain additional experience, and, although his salary is small, he says that he is satisfied.

COLORADO AGRICULTURAL COLLEGE

At a meeting of the Colorado Agricultural College Student Branch on May 29, Professor Crain addressed the society on the uniflow engine. He described first the heat loss that takes place in the counterflow engine, due to the condensation, and how the loss is minimized by the uniflow principle. He then described the Stumpf Uniflow Engine which has been developed in Germany. The Stumpf engines are run condensing, and, in order to meet the American requirement of running non-condensing, an auxiliary valve has been added. By means of diagrams, he illustrated the difference between the valves of the counterflow and those of the uniflow engines.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College on June 9, the following officers were elected for the coming year: L. A. Wilsey, president; J. I. Michaels, vice-president; F. R. Rawson, secretary, and Charles Zimmerman, treasurer.

W. L. Rhoades, a senior in the mechanical engineering course, gave a paper on Variable Compression on the Economy of a Corliss Engine, which were the results of a thesis which was carried on by him and A. H. Ganshird on the economy of a simple, non-condensing Corliss engine. They gave as the results of their tests that as the compression increased up to about eighty per cent of the initial steam pressure, the economy of the engine increased. From the results of Clayton's analysis, the conclusion was made that there was leakage past the piston of the engine used in the test.

Shelby Fell, a senior in the course of electrical engineering, gave a paper on Tests of a Mercury Arc Rectifier, which were the results of his thesis which was performed to determine the efficiency, shape of the wave and losses of a mercury arc rectifier.

PENNSYLVANIA STATE COLLEGE

A meeting of the Pennsylvania State College Student Branch was held on May 19. W. D. Garman, president of the Branch, read a paper on Student Branches of the A.S.M.E. issued by the Society.

The following officers were elected for the coming year: H. L. Munnaert, president; G. H. Dunn, vice-president; E. J. Kenney, secretary; P. N. Ziegler, treasurer, and Prof. J. P. Calderwood, of the Advisory Committee, to countersign checks.

PURDUE UNIVERSITY

A meeting of the Purdue University Student Branch was held on May 18, at which the following officers for the coming year were elected: W. F. Miller, chairman; R. B. Stein, vice-chairman; H. R. Snyder, recording secretary; L. C. McAuley, corresponding secretary, and O. P. Hambrick, treasurer.

C. T. Sprado, chief designing engineer with the Allis-Chalmers Manufacturing Company of Milwaukee, spoke on Gas Engine Practice. His discussion was mainly on the internal combustion oil engine, the study of which he has spent some twelve years. The oil engine that was described was the one made by the Allis-Chalmers Company. Illustrative slides were used, showing each part of the engine in detail. The engine is of very late development, very similar to the

gas or gasoline engine in construction. A horse-power, however, can be developed at a much lower figure than by either of the other engines. Each part of the engine was taken up and explained in detail, the first part discussed, being the different types of plungers used and the one that has proved most satisfactory. In discussing the different types of valves, Mr. Sprado made the statement that the valve being used at present on the piston is almost perfect in design. It has been tested in their shops, and has been in use on engines that run continuously twenty-four hours a day for six months without stop. The Allis-Chalmers engine has many improvements in the working of the piston which makes it distinctive above all other types.

Mr. Sprado also made a comparison of the vertical and horizontal types of engines. He disproved the idea that most people seem to have that the horizontal engine takes more floor space than the vertical. He showed that the lubrication of a horizontal engine was more thorough and the system much simpler. A vertical engine is not guaranteed to be started in less than five minutes and it is a considerable job. The horizontal engine made by the Allis-Chalmers people may be started in less than one minute. Following this, a few slides were thrown on the screen, showing efficiency curves of the different types of engines.

SYRACUSE UNIVERSITY

A meeting of the Syracuse University Student Branch was held on May 21, at which the following officers for the coming year were elected: D. R. Hay, president; S. S. Andursky, vice-president; H. B. Tracy, secretary, and E. H. Brooks, treasurer.

Dr. John E. Sweet gave a lecture on Harmony of Theory and Practice, and gave many examples where theory and practice do not harmonize. Principles worked out by scientists very many times cannot be adopted in engineering projects. The impression left with the audience was that an engineer's experience is worth much more to him than his technical training, but that he must have both to be successful, and that he must not place too much faith in pure science, but realize that he must separate by his accumulated knowledge the practical from the impractical.

THROOP COLLEGE OF TECHNOLOGY

At the regular meeting of the Throop College of Technology Student Branch, held on May 19, Harold Doolittle, assistant construction engineer of the Southern California Edison Company of Los Angeles, told about the construction and the operation of their plant at Long Beach. Most of the students had been to see this plant on an inspection trip a few weeks before this, so that the illustrations and descriptions given by Mr. Doolittle helped to make many of the things clear. This plant, supplying power to a large number of towns and cities of Los Angeles County, has three Curtis turbines, 12,000, 15,000 and 20,000 kva., with sufficient building space for the addition of a fourth unit.

On May 21, a meeting was held at which the following officers were chosen: V. E. Farmer, chairman; C. H. Ride-nour, vice-chairman; J. A. Beattie, secretary, and Arthur Stert, treasurer.

UNIVERSITY OF CINCINNATI

The largest meeting of the school year of the University of Cincinnati Student Branch was held on May 21, at which the

following officers were chosen: A. J. Langhammer, president; R. S. Rickwood, vice-president, and W. T. Cowell, secretary and treasurer. The speaker of the evening was A. M. Sosa, chief draftsman of the American Tool Works Company. His subject was Pitfalls Along the Path of the Young Engineer. The speaker pointed out that engineers after graduation separate very quickly, and that each individual had the same set of tools, so to speak, at his command. Now, if never before, the graduate will ask himself the questions: "What is my value? What have I learned and what have I yet to learn?" If an employer were to answer these questions, he would say: "You are praiseworthy, but you lack experience."

During his course the student has learned many things. He has studied physics, mathematics, mechanism, etc., and he has been taught to handle instruments skillfully. However, when a student assumes a position, his work is along one branch of the subject he has studied. He may find that this particular branch has been given but little time in his course. His efforts from now on are concentrated upon this one branch and its details; and as he progresses in his work his knowledge of the science of engineering increases and he gains his experience. The young engineer now realizes that by experience is meant the history of that particular branch of engineering which he is following.

Mr. Sosa emphasized that engineering work is primarily analytic, and if one error is made in the analysis the mistake will show. All engineering knowledge is the result of three things—observation, comparison and combination, and to get results, it is not necessary to know the precise nature of certain phenomena; for example, heat, electricity, friction, etc. We know that, under certain conditions, each will exhibit certain characteristics, and to a man on the job this is quite enough. When new fields are being explored, the methods are analogous; that is, certain facts are discovered, laws are formulated, and results are derived from these.

Professors A. L. Jenkins and A. C. Joerger gave short addresses.

UNIVERSITY OF MINNESOTA

A regular meeting of the University of Minnesota Student Branch was held on May 6, to which the whole sophomore mechanical engineering class was invited. Professors Martens, Shoop and Rowley, and Mr. Colvin, of the Post-seniors, spoke on the general theme of membership.

The meeting held on May 13 was open to the whole engineering college, at which H. S. Whiton, of the Minneapolis General Electric Company, spoke on System Operation. He very interestingly described the problems and woes of the operator of a large light and power distribution system like that in the city of Minneapolis. The slides which he used to illustrate his lecture showed the power plants and branch station of the Minneapolis General Electric Company.

The last regular meeting of the Branch was held on May 20. The meeting was called to order to give Mr. Shoop, of the Experimental Engineering Department, a chance to speak to the senior and post-senior men about connecting themselves with the national Society as Junior members.

UNIVERSITY OF NEBRASKA

At a meeting of the University of Nebraska Student Branch on May 4, the following officers were elected: L. L. Westling, chairman; R. B. Saxon, secretary, and W. C. Chapin, treasurer.

WORCESTER POLYTECHNIC INSTITUTE

At a meeting of the Worcester Polytechnic Institute held on May 21, the following officers were elected: Harold Nutt, chairman; Thomas W. Farnsworth, vice-chairman; John A. C. Warner, secretary, and Everett H. Francis, treasurer.

Following the executive business, abstracts from several senior theses were read. Among them were Investigation and Test of a White Gasoline Motor, by Harrison W. Hosmer and George W. Smith; Heat Treatment of High Speed Steels to Meet the Cutting Requirements of Different Metals, by Ralph C. Nourse and Austin E. Poirier; and Test of the Westinghouse Electric Lighting, Starting and Ignition System, by Clifton P. Howard and Raymond P. Lansing.

This meeting brought to a close the first year of the Worcester Polytechnic Institute Student Branch. The meetings of the year have been well attended, and, by resort to publicity, the open meetings have been well attended by an interested public, and it is believed that the work of the Branch has been of value not only to the Institute, but to the community as well.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 15th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. In sending applications stamps should be enclosed for forwarding.

0147 Designer on dies for forgings. Location, New York.

0148 Draftsmen wanted for work on small machine parts. Location, New York.

0149 Wanted: A man to analyze and make recommendations for cutting shop costs; must be familiar with the latest shop practice, be able to figure speeds and feeds and make time studies. Work covers foundry, pattern and machine shops and building power house equipment. Give full information in first letter. Name of company confidential. Location, New York State.

0153 Wanted for Pittsburgh territory young mechanical engineer, as engineering salesman for high grade power plant steam apparatus; condensers, jet apparatus, re-cooling plants, water heaters, etc. Some experience in selling preferred. Apply by letter.

0155 Sales manager for Chicago office of manufacturers of power accessories. Desire a man who is well acquainted with the mechanical engineers in Chicago and surrounding territory. Must be well versed in power plant work, industrious and not afraid to work. Apply by letter.

0156 Engineer for inspection of machine parts. Knowledge must cover quality of machine work and parts. Location, New York.

0158 Checkers on detail drawings of Diesel engines. Men of experience in checking drawings, but not necessarily those who have worked at this particular line. Location, New York.

0160 Young graduate in engineering who has had at least two years experience in heating and ventilation. Location, Michigan.

0163 Chemist for works of manufacturing chemist. Location, New Jersey.

0164 Foreman of shop for manufacturing chemist. Location, New Jersey.

0165 Assistant engineer with experience in supervision of power plant and factory design. Chemical plant experience specially desired, though not necessary. Location, New York.

0166 Position of general manager of sales is open to a man of ability and equipment with a large firm manufacturing heavy machinery. Experience in sale of both steam and gas engines essential. Name strictly confidential.

0167 Foreman for plant repair department of Connecticut concern; department is largely general mill repair work; must be able to handle machinists, millwrights, carpenters, blacksmiths, laborers, masons, etc., and should possess the ability to supervise and keep varied work going at the same time.

0168 Mechanical engineer, capable of taking charge of development department of company manufacturing stokers. Man having experience with forced draft stokers preferred. State age and experience, giving full details and salary expected. Apply through Society.

0170 A consulting engineer of New York, with practice in a special field which can be greatly extended, desires to take into partnership an engineer who can invest some money and with qualifications for conducting investigations in the fields of physics and applied mechanics. Apply by letter.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated in consecutive issues of the Bulletin. Names and records are kept on the office list three months, and at the end of such period if desired must be renewed.

G-170 Member, sales engineer, located in New York, good correspondent and estimator, broad acquaintance in manufacturing, engineering, and expert in field work, and experience in handling successfully well-known accounts in New England and Eastern States, desires to negotiate with manufacturer wishing a reliable representative in New York who will accept the responsibility for the management and results.

G-171 Member, with an unusually thorough experience in manufacture, and with first class record as executive, at present in successful consulting practice in scientific management, and especially successful in developing capable men, desires manufacturing executive position.

G-172 Member, graduate M.E., ten years experience in the operation of power plants, now specializing in selling coal to power plants, understands selling coal on specifications, desires position as fuel engineer with a dealer or producer of coal.

G-173 Graduate M.E., age 25, two years experience in office work and drafting department of a heating and ventilating concern, desires position in the same or along similar line.

G-174 Junior, aged 26, seven years experience embracing machine shop, drafting room, installation, production and estimating, desires position as assistant to executive or consulting engineer. At present employed but is seeking advancement.

G-175 Member, specializing in the installation of scientific management, can take on a limited amount of additional work.

G-176 Member, age 40, with 24 years of broad, practical and theoretical experience in erecting, operating and consulting capacities, also as master mechanic and mechanical superintendent in connection with the manufacture of ma-

chinery and prime movers, and in the maintenance, reconstruction and operation of paper and jute mills, desires position in either power plant or mill work.

G-177 Associate member with 20 years experience covering general office work, advertising, domestic and foreign sales, with knowledge of shop cost and wage systems and a wide general technical knowledge, has had more than four years business experience in fourteen foreign countries; broad acquaintanceship both at home and abroad and could develop foreign sales or promote manufacturing or sales branches abroad, desires to get in touch with growing concern that desires to increase business. Would accept a nominal salary with an agreement for bonus based upon results or a moderate fixed compensation.

G-178 Member, works manager and mechanical engineer, with nine years experience as engineer on water works, electric power station and steam engine work, twelve years experience as manager and designing engineer, manufacturing plant, building gas engines, automobiles, pumps, tractors and excavating machinery and with six years experience with efficiency methods, has managed 1900 men, laid out, built, equipped and organized plants, would like to build and organize new plant, or improve a growing plant.

G-179 Member, Cornell graduate, age 31, married, six years experience in refrigerating engineering and general power plant work, two years experience in teaching, desires position for the coming academic year in mechanical department of a technical school.

G-180 Member, age 46, technical graduate, married, experienced in engineering work with prominent engine builder and as resident engineer and chairman of safety committee of steel works, desires position. Salary, \$3000.

G-181 Factory superintendent or foreman, 15 years executive experience, capable of producing results; practical machinist, toolmaker, and thoroughly conversant with modern manufacturing methods, organizing and increasing production.

G-182 Technical graduate, wide experience as railway mechanical engineer, as machinist, motive power draftsman and mechanical engineer desires position along these lines, or one as mechanical inspector, assistant superintendent motive power, or assistant to general manager. Location, immaterial.

G-183 Associate-member, Stevens graduate, age 27, six years gas engine experience in designing, experimental, testing, machine shop work and sales, desires position as assistant to superintendent or other responsibility.

G-184 Engineer with five years experience in steam turbines, power plant and reinforced concrete work desires permanent position. At present employed.

G-185 Young technical graduate, single, desires work in any branch of the engineering profession.

G-186 Member with broad experience of over 20 years as general manager of large plant including foundry machine and metal working shops, also in charge of sales and financial development and practical experience in all departments, desires position along the same lines.

G-187 Associate-member, age 34, graduate M.E., ten years consecutive and successful experience from machine shop to designing engineer; four years experience in design and construction of ordnance equipment of navy department; five years in design of special machinery, hydraulic machinery and in layout of power plants. Has held positions as draftsman and designer and U. S. Junior engineer and as assistant engineer on construction. At present employed but desires to make change.

G-188 Member, technical graduate, 12 years experience in design, operation and maintenance of heat, light and power plants, especially in improvement and supervision of

power plant to obtain greater efficiency. At present employed but wishes to connect with firm of engineers or private corporation.

G-189 Member, age 37, technical graduate, two years consulting and betterment work in factories, ten years experience in designing, engineering production and accounting lines in manufacturing steam, gasoline and automobile engines and light and heavy machinery, desires position.

G-190 Junior, 1914 graduate Massachusetts Institute of Technology, desires position with a mill architect of manufacturing concern. Any position offering good experience and a chance for advancement will be considered.

G-191 Young engineer with technical training and two years experience in the design and manufacture of high duty pumping engines, and one year in the construction and maintenance department of large public service corporation in New York, desires position with a future with firm located in the Middle West.

G-192 Junior member, graduate in mechanical engineering, assistant to steam engineer in large manufacturing works, with experience in power plant supervision and boiler room efficiency, and with knowledge of power costs and distribution in manufacturing, desires position as steam engineer.

G-193 Junior member, Columbia graduate, thoroughly experienced in railway, construction and electrical lines, desires position with consulting engineer or contractor, or similar line. At present employed.

G-194 Junior member, graduate M.E., three years varied experience, desires position as laboratory instructor.

G-195 Junior member, Stevens graduate, energetic, resourceful, capable of handling men, eight years experience in engineering with firm manufacturing power plant equipment, also shop and drafting room experience, desires position which does not necessitate traveling. Has specialized in steam engineering.

G-196 Member, in consulting practice, with broad experience in perfecting general organization of manufacturing companies and in efficiency operation of plants, including familiarity with various processes of manufacture, particularly metal working, is open to temporary or permanent connection. Under suitable conditions will take stock or interest in profits as part compensation for services.

G-197 Junior member, age 27, Stevens graduate, possessing unusual mathematical ability, and with four years experience in experimental, plant and executive work, desires position. At present employed, but will be open for position in July.

G-198 Member A.S.M.E. and A.S.T.M., technical graduate, age 38, four years learning machinist trade, 13 years experience in executive positions with two companies manufacturing brass and iron steam specialties such as valves, lubricators, etc. Familiar with foundry, finishing and assembling operations.

G-199 Associate-member, graduate Swiss Government's mechanical school, command of French and German, eleven years practical experience as machinist, tool-die maker, tool department, foreman, draftsman, machine and tool designer and inspector, familiar with modern manufacturing methods, desires position with opportunity. Capable of handling men.

G-200 Mechanical engineer, technically educated, age 30, married, one and one half years shop experience and ten years practical experience in engineering departments of large concerns manufacturing valves, steam and engineering specialties well versed on power plants; executive ability.

G-201 Mechanical engineer with broad designing experience of steam pumps, open for position as draftsman, hav-

ing held similar position for years with a leading pump concern; best references.

G-202 Student member, age 22, graduate M.E. at Washington University; experienced in drafting, and in oil and cement testing; served time as special apprentice with large company manufacturing iron and steel products; testing or designing; middle west preferred.

G-203 Member, technical graduate, age 32, having two capable associates and centrally located office, will take additional representation in Philadelphia for reputable manufacturer who has at present no direct representative. The character of the product must be such that a considerable business will be a result of thorough and systematic engineering salesmanship.

G-204 Student member, 1915 graduate; four years shop and erecting experience. Location immaterial; future prospects most important consideration.

G-205 Student member, M.E. Columbia University, desires employment with an engineering or manufacturing firm. Willing to start at low salary if there are chances for advancement.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN ASSOCIATION OF DEMURRAGE OFFICERS. Proceedings of 26th Annual Convention, 1915. Gift of Association.

AMERICAN WOOD PRESERVERS' ASSOCIATION. Proceedings of 11th Annual Meeting, 1915. *Baltimore, 1915*. Gift of Association.

CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE. Publication no. 1. Some Roads towards Peace. *Washington, 1914*. Gift of Carnegie Endowment, etc.

CARNEGIE FOUNDATION FOR THE ADVANCEMENT OF TEACHING. Annual Report of the President, 1914. *New York, 1914*. Gift of Carnegie Foundation, etc.

CENTRIFUGAL FIRE PUMPS, E. E. Maher. Reprint from *Armour Engineer*, May 1915. Gift of author.

CINCINNATI WATER WORKS DEPARTMENT. Annual Report, 1914. Gift of J. A. Miller.

THE COMPETENT LIFE, Thomas D. West. *Cleveland, 1905*. Gift of author.

Essays on the development of human ability as an aid in the betterment of labor. Should be read by all who are interested in the improvement of the working man. W. P. C.

CONTROLLING THE COST OF ELECTRICITY, Walter N. Polakov. Reprint from May 1915, *Engineering Magazine*. Gift of author.

CRANES AND HOISTS, Hermann Wilda, translated from the German by Chas. Salter. *London, 1913*. Gift of Hunt Memorial Fund.

THE EFFICIENT MAN, Thomas D. West. Ed. 2. *Cleveland, Gardner Printing Co., 1914*. Gift of author.

Teaches the doctrine of work in the development of efficiency in man, and the causes of inefficiency. W. P. C.

EXPLOTACIÓN DEL PETRÓLEO DE COMODORO RIVADAVIA. Memoria Correspondiente a los años 1912/13. *Buenos Aires, 1914*. Gift of R. R. Edgar.

FLY WHEEL EXPLOSIONS, W. H. Boehm. Reprinted from *Insurance Engineering* June 1905. Gift of Fidelity and Casualty Company.

GESELLSCHAFT EHEMALIGER STUDIERENDER DER EDIG. TECHNISCHEN HOCHSCHULE IN ZÜRICH. Fünfzigstes Bulletin April 1915. Gift of Technischen Hochschule in Zürich.

LOWELL TEXTILE SCHOOL. Bulletin 1915-16. *Lowell, 1915*. Gift of Lowell Textile School.

MASSACHUSETTS. BOILER INSPECTION DEPARTMENT. District

Police. Steam Boiler Rules formulated by the Board of Boiler Rules. *Boston, 1915*. Gift of A. S. M. E.

MILWAUKEE (WIS.) SMOKE INSPECTOR. Annual Report, 1914. *Milwaukee, 1914*. Gift of Chas. Foethke.

NEW YORK STATE. DEPARTMENT OF HEALTH. Thirty-fourth Annual Report, 1913. *Albany, 1914*. Gift of State Department of Health.

PANAMA PACIFIC INTERNATIONAL EXPOSITION, SAN FRANCISCO, 1915. Official Swedish Catalogue. *Stockholm, 1915*. Gift of Commissioner General for Sweden.

POLYTECHNIC ENGINEER. vol. XV, 1915. *Brooklyn, 1915*. Gift of Polytechnic Institute of Brooklyn.

PURDUE UNIVERSITY. Alumni Register, 1875-1911. *Lafayette, 1912*. Gift of A. S. M. E.

SANITARY DISPOSAL OF MUNICIPAL INSTITUTIONAL AND INDUSTRIAL WASTE. THE MORSE DESTRUCTOR. *New York*. Gift of Jarvis-Morse Corporation.

STEAM BOILER EXPLOSIONS, W. H. Boehm. *New York*. Gift of Fidelity and Casualty Company.

TABLES ANNUELLES DE CONSTANTES ET DONNÉES NUMÉRIQUES. ART DE L'INGENIEUR ET METALLURGIS. Extrait du volume III, 1912. *Paris, 1914*.

DONNÉES NUMÉRIQUES ET L'ÉLECTRICITÉ, MAGNÉTISME ET ÉLECTRODYNAMIE. Extrait du volume III, 1912. *Paris, 1914*. Gift of University of Chicago Press.

These two pamphlets are reprints from the Annual Tables of Constants of the Portions relating (1) to Engineering and Metallurgy; (2) to Electricity, Magnetism and Electro-chemistry, thus placing at the disposal of the student at a small cost the essential standards. W. P. C.

TEST METHODS FOR STEAM POWER PLANTS, Edward H. Tenney. *New York, D. Van Nostrand Co., 1915*. Gift of publishers.

In connection with a large amount of experimental work done by the author, he has consulted numerous authorities as to testing methods. The methods gathered together in this book are those which he has found most satisfactory in practice. W. P. C.

VALVES AND VALVE GEARS, Franklin D. Furman. Ed. 2. Volume I—Steam Engines and Steam Turbines. *New York, J. Wiley & Sons, 1915*. Gift of publishers.

The chief aim has been to tell in particular, instead of in general, just how the engine or motor is regulated; also to tell how the valves and valve gears may be laid out, with due regard to the laws of mechanism, to give desired control of the steam or gas or other operating agent. W. P. C.

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL.

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879.

COMING MEETINGS OF THE SOCIETY

September 16-17, San Francisco, Cal. In common with the other national engineering societies, professional sessions will be held in San Francisco, September 16 and 17, previous to the meetings of the International Engineering Congress, which will occur during the week of September 20. Papers will be presented on the Exhibits and Engineering Features of the Panama-Pacific International Exposition, and on Oil Engines, with special reference to their use with California oils. The sessions will be held in the Hall of the Native Sons of the Golden West, Mason Street, between Geary and Post Streets. The headquarters of the Society will be at the Clift Hotel.

Annual Meeting, December 7-10, New York City. Arrangements have already been perfected for sessions by the sub-committees on Railroads, Textiles, and Protection of Industrial Workers, and it is expected that papers will also be contributed by the Committees on Machine Shop Practice, Industrial Buildings, and Air Machinery, besides the usual miscellaneous papers. The Railroad session will be devoted to a discussion of trucks for passenger coaches. The Textile session will have papers by engineers prominent in the textile field, on the relative values of purchased electric current, and of power from individual plants; hot water heating for textile mills; and the engineering features of insurance. The session on safety methods will be of interest to engineers generally. It is planned to have a discussion along broad lines, taking up the principles involved and the results obtained by safety methods, and their bearing on industry as a whole. *It is urged by the Committee on Meetings that all papers for the Annual Meeting be sent to the Secretary not later than September 1st, and that those who contemplate contributing papers notify the Secretary in advance of this date if possible. Papers should be typewritten, double or triple spaced, and drawings should be of such a character that tracings can be readily made from them for purposes of reproduction.*

THE SEPTEMBER MEETING

AND

THE INTERNATIONAL ENGINEERING CONGRESS, 1915

THE centre of gravity of the engineering profession in September will be the International Engineering Congress to be held in San Francisco during the week of the twentieth, and for this reason the September meetings of the four national engineering societies have been arranged to take place in that city during the week preceding the Congress. Also, members of the societies attending the meeting and Congress will be afforded the unique opportunity of visiting the Panama-Pacific International Exposition at San Francisco, the Panama-California Exposition at San Diego, as well as some of this country's most famous points of scenic interest on the route from the east to the west.

The Committee on Local Affairs in San Francisco has placed its services at the disposal of all engineers resident within the United States, so that those who visit San Francisco with their families and friends may be sure that special attention will be paid to their comfort.

THE JOURNEY TO SAN FRANCISCO

Arrangements have been made for a special train for members of the Society and their friends, leaving New York (Grand Central Terminal) on Thursday, September 9, at 7.45 p.m. The train will stop at Niagara Falls for four hours on Friday morning, allowing time for the members of the party who so desire to take the famous Niagara Gorge Trip. On Sunday morning the party will

arrive at Colorado Springs, where members will be enabled to tour Crystal Park and also journey to Pike's Peak, Garden of the Gods, Cheyenne Canyon and the Seven Falls. The Grand Canyon will be reached on Tuesday morning and fifteen hours will be spent there, which is ample time for excursions to Bright Angel Trail, Bottom of Canyon, Hopi Point, Hermit Rim Drive and Sunset Point. The party will arrive at San Francisco on Wednesday, September 15, at 9 a.m.

Reservations for this train are now being arranged by Mr. G. S. Harner, Passenger Agent, New York Central Lines, 1216 Broadway, New York City, and to secure desirable accommodations applications should be addressed directly to Mr. Harner as early as possible, mentioning the Society. The fare to San Francisco by this train and return by any route (except via Northwestern points) is \$98.80. Pullman rates, one way; \$22.00, lower berth; \$17.60, upper berth.

For those members of the Society who cannot join the party from New York, reservations are being made on the Sunset Limited, leaving New Orleans on Sunday, September 12, at 11 a.m., and arriving in San Francisco at 1.00 p.m. on Wednesday, September 15. Accommodations on this train can now be secured by addressing Mr. J. H. R. Parsons, General Passenger Agent, Southern Pacific Company, New Orleans, La. The round trip fare, New Orleans to San Francisco, is \$57.50 going and

TOWER OF JEWELS
PANAMA-PACIFIC EXPOSITION

NEW YORK STATE BUILDING

AVENUE OF PROGRESS

returning over the same route, or \$62.50 returning to Chicago. Pullman rates, one way: \$11.50, lower berth; \$9.20, upper berth.

THE SEPTEMBER MEETING

The professional sessions of the September meeting of the Society will be held in the Hall of the Native Sons of the Golden West, Mason Street, between Geary and Post, San Francisco, on the mornings of Thursday, September 16, and Friday, September 17. While the program has not been fully completed, it can be stated that there will be papers on Thursday morning treating comprehensively of the exhibits and the engineering features of the Panama-Pacific International Exposition, and on Friday there will be papers and discussion on the subject of the oil engine with special reference to its use with California oils.

HEADQUARTERS IN SAN FRANCISCO

The headquarters of the Society will be the Clift Hotel, at the corner of Geary and Taylor Streets, San

Francisco. For members who desire to be accommodated at this hotel, a number of rooms have been arranged for. The rate is \$5.50 for each room, to be occupied by one or two persons, and to include bath. Each member should make his own reservation direct with the hotel, mentioning the Society.

For convenience, the rates at other hotels as quoted to the Society are given below:

Palace Hotel, Market and New Montgomery Streets, \$4.00 per day, room and bath, one person.

Fairmont Hotel, California and Mason Streets, \$4.00 per day, room and bath, one person.

Hotel St. Francis, Geary and Powell Streets, \$7.00 per day up, room and bath, two persons.

Hotel St. Regis, 83 Fourth Street, \$2.50 per day up, room and bath, two persons.

Information regarding accommodations at any other hotels may be obtained by addressing the Official Exposition Hotel Bureau, 702 Market Street, San Fran-

VARIED INDUSTRIES AND MINES

COURT OF FOUR SEASONS

PALACE OF EDUCATION

COLUMN OF PROGRESS

cisco. This Bureau also undertakes to make reservations in approved hotels without charge.

MEETINGS OF OTHER SOCIETIES

The American Society of Civil Engineers, the American Institute of Mining Engineers, and the American Institute of Electrical Engineers will also hold September meetings in San Francisco on the days preceding the Congress.

The headquarters of these societies and their places of meeting are listed below:

<i>Society</i>	<i>Headquarters</i>	<i>Meetings</i>
A. S. C. E.	St. Francis Hotel	Same
A. I. M. E.	Hotel Bellevue	Same
A. I. E. E.	St. Francis Hotel	Civil Center Auditorium

The meeting of the American Society of Civil Engineers is the Forty-seventh Annual Convention of the Society. The programme includes a welcoming address by President Charles D. Marx; a Panama Canal ses-

sion; a reception, dinner and dance in the Old Faithful Inn on the grounds of the Panama-Pacific International Exposition, and excursions to Del Monte, Santa Cruz and San José. The Society, through its Secretary, Chas. Warren Hunt, has extended a cordial invitation to the membership of our Society to participate in these events. The dates of this convention are September 16 to 18.

INTERNATIONAL ENGINEERING CONGRESS, 1915

The holding of a Congress of Engineers from the great associations of the world on the scene of the celebration of the completion of the Panama Canal was conceived as far back as 1912. In February of that year a convention of engineering societies was held in San Francisco, and as the outcome of the recommendations there made the International Engineering Congress, 1915, was organized.

Indefatigable have been the efforts of the Committee of Management of the Congress to secure the success

PALACE OF MANUFACTURES

COLONNADES, COURT OF FOUR SEASONS

of the enterprise by the coöperation of members from the national engineering societies. The last report of this committee announced that practically three thousand members had been enrolled and almost two hundred papers had been received.

The Congress will publish ten volumes of proceedings on the following topics: The Panama Canal; Waterways, Irrigation; Municipal Engineering; Railways, Railway Engineering; Materials of Engineering Construction; Mechanical Engineering; Electrical Engineering, Mechanical Engineering; Mining Engineering, Metallurgy; Naval Architecture and Marine Engineering; miscellaneous, including Military Engineering, Aeronautical Engineering, and Heating and Ventilation.

Members of the Society still have an opportunity of enrolling in the Congress if they wish to do so. The fee is nominal, five dollars, and entitles the subscriber to a certificate of membership, to participation in the deliberations of the Congress, to an index volume of the proceedings, and to one of the volumes listed above. Remittances may be made to Mr. W. A. Cattell, Secretary, Foxcroft Building, San Francisco.

The Congress will be opened at 10 A.M. on Monday, September 20, in the new Auditorium Building, where the subsequent sessions will be held. At the opening session there will be addresses of welcome and responses, an address by General George W. Goethals, Honorary President, and the presentation of the John Fritz Medal to Dr. James Douglas. The second session will be devoted to the Panama Canal, and sessions on the topics mentioned above will follow through the week.

EXCURSIONS IN AND AROUND SAN FRANCISCO

For the benefit of members visiting San Francisco for the September meeting and the Congress, the following excursions to important engineering activities in California have been arranged. Some of these will be by automobile without expense, and others will only entail the cost of a round trip ticket.

- September 18: San Francisco High Pressure Fire System.
Portrero Gas Works Electric Station A, Pacific Gas & Electric Co.
Spring Valley Water Works.
- September 19: Delta Lands of the Sacramento and San Joaquin Rivers.
Spring Valley Water Works.
- September 17 to 18: Great Western Power Company's Hydroelectric development on the Feather River.
Gold dredging at Oroville.
- September 18 to 19: Pacific Gas & Electric Co.'s Hydroelectric development at Lake Spaulding and Drum Power House.

North Star & Empire Mines at Grass Valley.

September 17 to 19: Oil fields at Coalinga.

THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION

Of the eleven main exhibit palaces of the Exposition, some of which are here illustrated, those of particular interest to the members of the Society will be the Manufactures and Varied Interests Building; the Machinery Building; the Mines and Metallurgy Building, and the Education Building.

The great palace of Machinery is the largest on the Exposition site and is nearly a thousand feet in length. In this palace numerous groups comprising examples of steam generators and motors, internal combustion motors, hydraulic motors, and wood and metal working tools are shown.

The exhibits in the palace of Mines and Metallurgy deal with the natural mineral resources of the world, their conversion into metal and manufacture in raw materials and forms for the various industries.

Education is represented by examples including methods of vocational training and municipal training, in addition to general educational work of schools and universities.

The Manufactures and Varied Industries palace contains products of manufacture and manual skill from all nations of the world.

THE PANAMA-CALIFORNIA EXPOSITION

Now being held at San Diego, California, this is also within easy reach of those visiting the Pacific Coast. This Exposition is also in commemoration of the opening of the Panama Canal, but its theme is the exploitation of the possibilities and opportunities of the various sections of this coast, from Alaska to Peru.

The Exposition is staged in Balboa Park, in the heart of the city of San Diego, and its exhibits are grouped in an educational and attractive manner in twelve buildings.

THE RETURN FROM SAN FRANCISCO

Members of the party journeying to San Francisco by the Engineers' Special have the privilege of returning by one of several routes, of which the following are examples:

- Via Southern Pacific or Western Pacific to Ogden and Salt Lake City, over the Rocky Mountains to Denver or Cheyenne, thence via Chicago or St. Louis.
- Via Los Angeles, San Pedro Route to Salt Lake City, and thence as above.
- Via Los Angeles, the Santa Fé Route through Albuquerque (also Denver if desired) to Chicago.
- Via Los Angeles, El Paso and the Rock Island Route to Chicago.
- Via Los Angeles and El Paso to New Orleans, thence via St. Louis, Chicago or Cincinnati.

Via Portland, Tacoma, or Seattle, thence via Ogden and Salt Lake City and the Rocky Mountains to Cheyenne or Denver, and Chicago or St. Louis.

Via Portland, Tacoma and Seattle to St. Paul, thence via Chicago.

Via Portland and Tacoma to Seattle, steamer or rail to Vancouver, thence via the Canadian Rockies, Winnipeg and St. Paul to Chicago.

Mr. Harner, the New York Central Lines agent, will quote any member the rates for return by any of the above or any other routes.

Navy Advisory Board

Following the announcement in the daily papers of the organization of an Advisory Board for the U. S. Navy, of which Thomas A. Edison is Chairman, the Society received an invitation from the Honorable Josephus Daniels, the Secretary of the Navy, asking the appointment of two members to serve on the Board.

Similar invitations have been extended to several other scientific and engineering societies, with a view to having the Board representative of the most advanced thought and experience in the various lines of engineering activity and scientific research.

Inasmuch as there will be no regular meeting of the Council until October, the Executive Committee of the Council took the matter under consideration and have arranged for a ballot by the Council by which means it is expected that an early selection of representatives will be made. It is the desire that the appointees to the Advisory Board should be distinctly representative of the mechanical engineers of the country and the aim will be to select men of foresight and executive ability in combination with inventive talent.

Joint Committee on Standards for Graphic Presentation

Preliminary Report published for the purpose of inviting suggestions for the benefit of the committee

As a result of invitations extended by The American Society of Mechanical Engineers, a number of associations of national scope have appointed representatives on a Joint Committee on Standards for Graphic Presentation. Below are the names of the members of the committee and of the associations which have cooperated in its formation.

- WILLARD C. BRINTON, *Chairman*, American Society of Mechanical Engineers.
(7 East 42nd Street, New York City.)
- LEONARD P. AYRES, *Secretary*, American Statistical Association.
(130 East 22nd Street, New York City.)
- N. A. CARLE, American Institute of Electrical Engineers.
- ROBERT E. CHADDOCK, American Association for the Advancement of Science.

1 Copies may be had from THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, 29 West 39th St., New York: 5 cents to members, 10 cents to non-members

- FREDERICK A. CLEVELAND, American Academy of Political and Social Science.
- H. E. CRAMPTON, American Genetic Association.
- WALTER S. GIFFORD, American Economic Association.
- J. ARTHUR HARRIS, American Society of Naturalists.
- H. E. HAWKES, American Mathematical Society.

The committee is making a study of the methods used in different fields of endeavor for presenting statistical and quantitative data in graphic form. As civilization advances there is being brought to the attention of the average individual a constantly increasing volume of comparative figures and general data of a scientific, technical and statistical nature. The graphic method permits the presentation of such figures and data with a great saving of time and also with more clearness than would otherwise be obtained. If simple and convenient standards can be found and made generally known, there will be possible a more universal use of graphic methods with a consequent gain to mankind because of the greater speed and accuracy with which complex information may be imparted and interpreted.

THE FOLLOWING ARE SUGGESTIONS WHICH THE COMMITTEE HAS THUS FAR CONSIDERED AS REPRESENTING THE MORE GENERALLY APPLICABLE PRINCIPLES OF ELEMENTARY GRAPHIC PRESENTATION

1. The general arrangement of a diagram should proceed from left to right.

2. Where possible represent quantities by linear magnitudes as areas or volumes are more likely to be misinterpreted.

3. For a curve the vertical scale, whenever practicable, should be so selected that the zero line will appear on the diagram.

FIG. 3

FIG. 4

4. If the zero line of the vertical scale will not normally appear on the curve diagram, the zero line should be shown by the use of a horizontal break in the diagram.

FIG. 10

10. The curve lines of a diagram should be sharply distinguished from the ruling.

FIG. 5A

FIG. 5B

FIG. 5C

5. The zero lines of the scales for a curve should be sharply distinguished from the other coordinate lines.

FIG. 6A

FIG. 6B

FIG. 6C

6. For curves having a scale representing percentages, it is usually desirable to emphasize in some distinctive way the 100 per cent line or other line used as a basis of comparison.

FIG. 7

7. When the scale of a diagram refers to dates, and the period represented is not a complete unit, it is better not to emphasize the first and last ordinates, since such a diagram does not represent the beginning or end of time.

FIG. 8

8. When curves are drawn on logarithmic coordinates, the limiting lines of the diagram should each be at some power of ten on the logarithmic scales.

FIG. 12

12. The horizontal scale for curves should usually read from left to right and the vertical scale from bottom to top.

FIG. 13A

FIG. 13B

FIG. 13C

13. Figures for the scales of a diagram should be placed at the left and at the bottom or along the respective axes.

FIG. 14A

FIG. 14B

FIG. 14C

14. It is often desirable to include in the diagram the numerical data or formulae represented.

FIG. 9A

FIG. 9B

9. It is advisable not to show any more coordinate lines than necessary to guide the eye in reading the diagram.

Year	Population
1840	17,069,453
1850	23,191,876
1860	31,443,341
1870	38,558,371
1880	50,155,783
1890	62,622,250
1900	75,594,575
1910	91,972,266

FIG. 15

15. If numerical data are not included in the diagram it is desirable to give the data in tabular form accompanying the diagram.

FIG. 16

16. All lettering and all figures on a diagram should be placed so as to be easily read from the base at the bottom, or from the right-hand edge of the diagram as the bottom.

ALUMINUM CASTINGS OUTPUT OF PLANT NO. 2, BY MONTHS, 1914
OUTPUT IS GIVEN IN SHORT TONS
SALES OF SCRAP ALUMINUM ARE NOT INCLUDED

FIG. 17

17. The title of a diagram should be made as clear and complete as possible. Sub-titles or descriptions should be added if necessary to insure clearness.

LIBRARY SERVICE BUREAU

With a view to bringing closer to members the facilities and usefulness of our splendid technical library, the Library Board has inaugurated a Service Bureau whose duty it will be to maintain a staff of expert searchers and translators to insure prompt and thoroughly efficient service to those members who live at such distance from New York as to make it inconvenient for them to consult personally the books and periodicals, and to those New York members who desire to avail themselves of this service.

Members who desire to be kept posted on the current publications of any engineering subject may receive such service by signing a form which states:

I hereby subscribe \$10.00 for Library Service for one year from date with the understanding that the subscription shall apply on service which I may request with reference to the following:

- Reference cards
- Translating
- Copying
- Bibliographing
- Abstracting
- Searches for patent purposes
- Statistical searches and reports

The Library is not permitted to carry on any work of a commercial character and, therefore, the prices charged members for service are kept down to a merely self-supporting basis. For the purpose of economic administration the subscription feature previously referred to has been established.

Forms have been prepared for the use of those desiring to receive regular service which give the schedule of charges for the different classes of service.

All the work done by the Library Service Bureau is strictly confidential, and this feature is especially important in relation to searches made for patent purposes.

At present there are in the Library over sixty thousand volumes on technical subjects, and there are received currently over one thousand engineering or scientific periodicals. In addition, the searchers have ready access to the New York Public Library and the Library of the Chemists Club.

For those members who are personally able to use the library a bibliography on any subject will, on request, be prepared by the Bureau, and with adequate prior notice, the volumes relating thereto will be set apart for personal perusal.

It is desired that all members shall become better acquainted with the facilities of the splendid library they own, and with the advantages which can be secured by those who avail themselves of the aid furnished by its Service Bureau.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON SEPTEMBER 10, 1915

MEMBERS are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their ages would qualify them and not with regard to professional qualifications, i. e., the ages of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Society by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential, and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received before September 10, 1915.

APPLICATIONS TO BE IN TIME FOR THE ANNUAL MEETING MUST BE ON FILE BY AUGUST 23

The fact that it takes at least three months to complete an election to membership, makes it necessary to post, in the September issue of The Journal, applications for membership which are to be acted upon in season for successful candidates to attend the Annual Meeting as members of the Society.

Members who have friends wishing to join the Society this year will be interested in having this information available, as many do not realize that it is necessary to take action so far in advance.

This is the most desirable time of the year at which to apply, because newly-elected members not only have the privilege of participating in the Annual Meeting, but obtain membership in time to have their names included in the Year Book of the Society, which goes to press annually on January 2d; they also have the opportunity of taking part in any of the meetings held by Local Sections in fourteen of the principal industrial centers of the country.

The advantages offered members are being constantly increased with an aim to fill completely the broad field of usefulness of a national engineering society, efficiently advance the interests of the profession as a whole and be especially helpful to every member of the organization.

Information regarding the Society and the requirements for membership will be promptly forwarded to any persons suggested by members.

SPRING MEETING PAPERS

At the Spring Meeting held at Buffalo, June 22-25, fourteen papers were presented, comprehensive abstracts of which are to be published in The Journal with an account of the discussion. Pamphlet copies of the complete papers without the discussion are available at the prices named in each case. Later, the papers which appear in volume 37 of Transactions may be had in pamphlet form with the discussion added.

A STUDY OF AN AXLE SHAFT FOR A MOTOR TRUCK

BY JOHN YOUNGER, BUFFALO, N. Y.

Member of the Society

While the investigation herein described is one which the writer made to determine the cause of failure of an axle shaft for a large motor truck and also the remedy adopted, it has a very much wider application than to motor trucks, and is testimony to the value of heat-treated steels.

The shaft is shown in Fig. 7 and with its adjacent parts

CHEMICAL

	Per cent.
Carbon about	20
Chromium about	1.5
Manganese about	30
Nickel about	1.00
Silicon about	20
Phosphorus and sulphur below	.04

PHYSICAL

	Lb. per sq. in.
Elastic limit	90,000
Maximum strength	105,000
Reduction in area	66
Elongation	25

The following are the particulars of the motor truck upon which all calculations of strength must be based:

Motor develops 44 h.p. at 1000 r.p.m. under average conditions.

FIG. 1. DIAGRAMMATIC DESIGN OF TRUCK REAR AXLE SHOWING LOCATION OF SHAFT

in Fig. 1. The flutes or splines at the ends are slightly free so that the shaft is under no constraint except to move in a rotary path; in other words it is intended to be subject to pure torsional stresses, with no complicating bending effects. The shaft was made from 2¼-in. diameter chrome nickel bar, turned all over to 2.1235 in. diameter. The shafts broke in service as shown by the illustrations, Figs. 2, 3, 4, and 5. The specifications of the steel read as follows:

Transmission reduction is 3.77 to 1.

Worm gear reduction is 9.75 to 1.

Total reduction, 36.8 to 1.

From various tests the efficiency of the transmitting mechanism between motor and axle shafts on this gear ratio is about 75 per cent., so that therefore 33 h.p. are transmitted as a maximum by the shafts at 27 r.p.m. But, in common with usual road vehicle practice, a differential gear is fitted, so that the power transmitted by each shaft at the wheel is only half the total; the shaft shown in Fig. 7, therefore, is under maximum pure torsional stress due to the transmission of 16½ h.p. at 27 r.p.m.

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion; 5 cents to members; 10 cents to non-members.

FIG. 2 CHARACTERISTIC FRACTURE, SHAFT TURNED DOWN

In considering the effective diameter on which to base calculations of stress, the large diameter of 2 1/4 in. would not be accurate, inasmuch as the flutes at the ends weaken the shaft to a considerable extent, as is obvious from Figs. 2 to 5, where the lines of cleavage are clearly seen to start from the corner of the spline. While it is true that a sharp corner is a very dangerous source of weakness, it was impossible to get a radius of more than 0.02 in. at the fillet without reducing the area of bearing surface. Key seats or splines are always weakening elements, but it is unfortunately impossible to do without them. The diameters of the plain shafts were the same as the diameters of the splined shafts at the bottom of the key-ways. The limit of elasticity and the torque at fracture for the splined pieces are seen to be slightly greater than that for the plain. Yet, when we turn to the work required to produce fracture, we find it takes more energy to break the plain shaft than it does the splined. It would certainly seem as if the projections should give an added strength to the shaft; yet in the ultimate their presence seems to hasten its down-fall. This is borne out by the appearance of the fractures in Figs. 3, 4, and 5, and it would seem that, while the splines add a slight extra strength to the shaft under static conditions, they subtract from it under dynamic conditions where fatigue is likely to result.

Taking the energy required to fracture, a plain shaft could be considered 30 per cent. to 60 per cent. stronger than a shaft with splines added. The immediate conclusion therefore would be that calculation for strength should be based at most on the diameter at the bottom of the splines.

In order to try out practically the value of this conclusion, a truck was loaded up to full 5 tons capacity. Its rear wheels were then anchored somewhat in a cradle, which would allow about 6 ft. of travel, Fig. 10. A driver then made the truck surge to and fro, the extent of the alternations being measured. The idea was to give the maximum stress on the axles by obtaining the full force of the motor as well as the rotational energy of the flywheel acting against the inertia of the truck. One shaft was left parallel in its length, the other was turned down in the centre. The for-

mer broke first and the latter some little time after, 5141 blows being necessary. The total twist in the second exceeded 700 deg., whereas the twist in the first was through an exceedingly short length, all being concentrated near the end of the splines (Fig. 5). It is interesting to note in Fig. 6 the beginning of the planes of cleavage.

From this test the conclusion is justified that the diameter at the bottom of the splines is to be taken in calculations for strength. Accordingly, the design was changed to that of Fig. 8 in which the diameter at the bottom of the splines is 1.75 in. The shaft formula therefore gives

$$\text{Maximum stress per square inch} = \frac{321,000 \text{ h.p.}}{n^2}$$

$$= 36,500 \text{ lb. per sq. in., approx.}$$

This gives a factor of safety of 2.5 based on the elastic limit, or 2.9 based on maximum tensile strength.

FIG. 3 CHARACTERISTIC FRACTURE, PARALLEL SHAFT

Regarding braking problems, this particular design of truck has a powerful brake located near the transmission, so that all the braking effort is transmitted by the rear axle shaft to the wheels. We are quite safe in assuming a maximum load on each rear wheel of 8000 lb. and a coefficient of adhesion of the rubber tire to the road, of 0.6. The diameter of the wheels is 40 in., so that torque on shaft is 96,000 in.-lb. The writer does not believe that we really get this

FIG. 4 EFFECT OF SPLINE

torque owing to the elastic rubber tires absorbing part of this blow; but assuming that it were obtained, we would have a maximum stress of 93,000 lb. per sq. in. set up in the axle from the formula

$$\text{Twisting moment or torque} = \frac{\pi}{2} f r^3$$

(It must be understood that the above loads are not normal working loads, but are the maximum that can be expected. It is obvious, therefore, that the shafts which have broken may have been considerably overstressed, although a large number of these actually ran high mileages up to 30,000 and 40,000 miles before breaking. For this reason, it was felt, that a comparatively small increase in strength might be sufficient to prevent such breakages and a set of experiments was put in hand to determine the governing factors. The necessity for this lay in the fact that it was almost impossible to increase the diameter of the shafts, which was, of course, the obvious step to take.

A study of the fractures shown in Figs. 2 to 5 convinced us that the large splines were a very grave source of weakness. If each spline is considered as a small cantilever of breadth $2b$ jutting out from the shaft, with a load of $2W$ upon it, the bending moment at the junction will be $2Wb$; if we take double the number of splines, but keep the same total bearing area, each spline will have half its former breadth and carry half its former load and the bending moment will then be $\frac{Wb}{2}$, or only $\frac{1}{4}$ of the above. In addition to the gain in strength by this change, the diameter of the shaft at the bottom of the splines can be increased by the

FIG. 5 CHARACTERISTIC FRACTURE

9) with 12 splines and with effective diameter increased from 1.75 in. to 1.8965 in., representing an increase in strength of

$$\frac{1.9}{1.75} = \frac{6.86}{5.36} = 28 \text{ per cent approx.}$$

The body of the shaft was ground and polished to avoid all scratches. It was found from examination of fractures that the slightest flaw was enough to start a breakdown. Particular attention was given to the junction of the main body of the shaft with the parts of larger diameter used for the splines, to avoid grooving of the filleting tool.

The designer naturally looks first to the manufacturing end as the cause of his troubles and one of the first investigations was to assure that the axle was subjected to pure torque and not a combined bending and twisting stress. Half a dozen complete axles, some of which had run up large mileage with no fracture, and the remainder had fractured in their early life, were inspected in detail; no difference was found, the only errors present

being those that fell within what could only be considered as limits of tolerance. This disposed effectually of improvement being effected in machining process.

The other variables being disposed of, the question of material only remained. It had first been the impression that the best material available was being used, and certainly the first physical tests indicated a high grade of alloy steel. The writer had noticed the curious fact, however, that the energy required to fracture a piece of ordinary soft mild steel was practically the same as that required to fracture an exactly similar piece of high-grade alloy steel. Several tests which the writer has witnessed have even shown that a soft steel bar requires more energy to break it than does a hardened bar.

The question, therefore, at once suggested itself: "Should the shaft be of a softer steel

capable of twisting more under a suddenly applied load, and afterwards returning to normal conditions; or should it be of a very much harder steel, which would be more rigid and not deflect so much, but which would require a greater load to break?" The writer reasoned that if the elastic limit could be raised materially, the shafts would stand up better. Experiments made with small heat-treated specimens, which

FIG. 6 LINES SHOWING PLANES OF CLEAVAGE IN A SHAFT ABOUT TO BREAK

height of one spline, and yet keep the outside diameter the same. It was felt, also, that, as the strength should be calculated from the diameter at the bottom of the splines, it would be advisable to turn down the shaft in the middle and so reap the advantage of having it uniformly strong throughout its length, and avoid trouble due to sudden changes in torque-resisting values. This, therefore, gave a shaft (Fig.

could be bent by hand, indicated that this was on the right path and accordingly, after some experiments, two shafts were heat-treated to 175,000 lb. elastic limit (measured in the usual way), and tested on a truck in very severe service; these stood up.

Further tests showed the desirability of increasing the carbon content somewhat, and several shafts were made to the new specifications and sent out on hard service with ex-

pected when hot, under a press. Each individual shaft is then put under the brinell hardness machine, and its brinell number read at the ends and the middle of the bar. This should be 402 to 444. It is then wrapped around with a metal tag, used with the idea of getting reliable results on the different steels we were trying out in our search for a suitable material. In this connection it is interesting to note that 5 per cent nickel steels, chrome vanadium steels, and air hardening

FIG. 7 THE ORIGINAL SHAFT

FIG. 8 SECOND DESIGN OF SHAFT

FIG. 9 FINAL FORM OF SHAFT

cellent results. The material was a domestic steel of the following characteristics:

CHEMICAL		PHYSICAL	
	Per cent		Lb. per sq. in.
Carbon about	. 30	Elastic limit	175,000
Manganese.	. 50	Tensile strength	185,000
Chromium.	. 1 5		
Nickel....	. 3 5		
			Per cent
		Elongation per cent in 2 in.	14
		Reduction of area	53

These experiments proved so satisfactory that in September, 1913, a number of these heat-treated shafts were sent out to replace others. Not one of these nor the original experimental shafts have broken, to the best of the writer's knowledge.

The shafts are machined from hot-rolled bars already heat-treated to show an elastic limit of about 100,000 lb. They are then heated in a gas furnace to a temperature of between 1450 and 1500 deg. Fahr., and quenched in oil. (This double treatment is to insure the grain being properly refined.) They are then reheated to a little over 700 deg. Fahr., and allowed to cool slowly in the air.

Some trouble was experienced at first with warping, but slight experimenting showed they could be readily straight-

ened when hot, under a press. Each individual shaft is then put under the brinell hardness machine, and its brinell number read at the ends and the middle of the bar. This should be 402 to 444. It is then wrapped around with a metal tag, used with the idea of getting reliable results on the different steels we were trying out in our search for a suitable material. In this connection it is interesting to note that 5 per cent nickel steels, chrome vanadium steels, and air hardening

steels were tried out and so far all have been standing up to service. The physical specifications of all these steels are very much alike. The success, therefore, seems due entirely to the higher elastic limit, especially as a number of these axles had six flutes and were not of the later 12-flute type. As a secondary result of the investigations it was thus definitely established that under pure torsional conditions the strength of a shaft is increased by increasing its elastic limit by heat treatment. It would naturally follow, therefore, that similar results could be expected from other components under tensile or shear stress, and accordingly greater attention has been paid to heat treating. The elastic limit has been raised in many pieces with corresponding advantage and, in addition, as a special measure of precaution, each important structural forging or bar is submitted to test on either the scleroscope or the brinell machine to insure that the piece has been properly treated. Both these machines give very reliable readings which can be directly compared with the elastic limit, and by their use a number of forgings seemingly all right, but actually either too hard or too soft, have been detected.

As regards the economic aspect of the use of heat-treated steels, it is found that this process costs between 2 and 2 1/2

cents per lb. and as the strength can in many cases be nearly doubled it clearly effects a large saving. Alloy steels, properly heat treated, are indispensable for motor truck work, as their capacity to resist fatigue is very great. The writer looks forward to their extended use among other mechanical engineers, just as the ball bearing first introduced for cycle and automobile work is now becoming a universal friction saver. As a permanent repair the heat-treated piece of steel is in many cases worth its weight in gold.

DISCUSSION

II. WADE HIBBARD said that, as a member of the Jury of Awards in San Francisco in the Bureau of Engineering, he made use of his privilege to inquire from many of the exhibitors regarding the use in power machinery of heat-treated alloy steels, and confessed that it was a disappointment to find how little it was being used.

He would ask the author to tell in his closure what he means by "elastic limit?" Is it the commercial elastic limit or drop of the beam; or is it a more scientific elastic limit obtained by means of an extensometer, electric contact or otherwise?

With reference to the strains which occur in connection with the reversal of loads, there are Wöhler's experiments and the experiments of those who have followed Wöhler, accounts of which are to be found in any good book on machine design.

CORNELIUS T. MYERS¹ (written). Mr. Younger has treated his subject with characteristic thoroughness and the conclusions set forth, I believe, are worthy of more than mental note by those members of the Society to whom the matter is at all pertinent. The strides made by the automobile industry, comparatively a youngster among the industries of the nation, have not been accomplished without much careful application of mechanical and metallurgical engineering. Analogous problems confront us in the older branches of industry and the suggestions that can be gotten from even a cursory study of the methods in vogue in automobilism should be well worth while.

RADCLIFFE FURNESS² (written). I should like to point out that by increasing the carbon in the material the author increased the true elastic limit and, therefore, the proportion between this and the yield point, thus having a much greater factor of safety in the higher carbon material than existed in the low carbon material.

The two points which are brought forcibly to my mind by Mr. Younger's paper are: First, the desirability of an engineer making a thorough and careful study of the physical properties of the metal which he has in mind to use, in conjunction with the work that he expects this metal to perform, the test conditions being exactly similar to the actual conditions. This has been done by the author in his paper, to my mind, in a most thorough manner.

Secondly, Mr. Younger mentions that alloy steels properly heat-treated are indispensable to motor truck work. Since this is so, it immediately comes to the mind of anyone familiar with metallurgy that the converse is true: namely,

that alloy steels improperly heat-treated are actually a menace to all work where they are used and, in addition, should never be used when not given a known and thoroughly tried heat treatment.

In the fabrication of any steel forging, one is obliged to heat the steel above the critical temperature, which is the temperature at which remarkable changes take place in the molecular arrangement. Since the final physical properties depend upon the rate at which the steel cools through the critical range, the number of degrees heated above the critical range, or the time that it has been held at the temperature

FIG. 10 "CRADLE" IN WHICH TRUCK WAS SURGED TO AND FRO BY ITS OWN POWER

above the critical range when forgings are being manufactured, one can readily see that forgings are subjected to heat treatment in the process of fabrication.

Alloys are added to steel because they emphasize the changes that can be brought about by heat treatment in the molecular arrangement and thus increase the physical properties that can be obtained from the material in hand. Thus, by the addition of alloys, one is emphasizing the difference that can be obtained by varying heat treatments. If the forgings are given no definite heat treatment and are being turned out at different rates, they will be subjected to varying heat treatments and, although it is possible in fabrication to turn out an article which has all the properties of a piece that has been put through a carefully thought-out and prescribed heat treatment, the likelihood of accomplishing this, when the chances of producing other results are infinite, is so small as to be negligible. In addition, one would have many forgings of varying physical properties from the varying heat treatments which they of necessity receive. It becomes necessary, therefore, to treat the material to bring it to a known standard; and, since one has increased the susceptibility by addition of alloys, it is evidently more necessary to heat-treat alloy steels than in the case of simple carbon steels.

It is the duty of all who are interested in the success of alloy steels to emphasize on all occasions the desirability of putting the steels into the condition which will give the best possible results, and of removing the common but fast dying

¹ Engineer, The Timken-David Brown Co., Detroit, Mich.

² Midvale Steel Co., Philadelphia, Pa.

impression that a steel, because it is a nickel, nickel-chrome or chrome-vanadium steel, is better than a plain carbon steel, no matter what heat treatment it may have received, when as a matter of fact the contrary is really true.

The AUTHOR: In reply to Mr. Furness as to the probability of a mistake in heat-treated alloy steels, one method of guarding against this is to subject each individual forging to either a brinell test or a scleroscope test.

Forgings of alloy steel are expensive and the author believes that it is just as necessary to inspect them for the heat treatment as it is to put the gage or a rule alongside of them to find out if they measure correctly. For that reason, therefore, he has an inspection put on each forging consisting of either a scleroscope test or a brinell test in order to insure that the heat treatment has been properly carried out. It is found these two tests give a very good indication of the state of the metal.

With regard to Professor Hibbard's question, the elastic limit of 175,000 lb. is by drop of beam,—the ordinary commercial elastic limit. The extensometer tests show a slightly lower elastic limit. From observation of tests of the axles and from breaking pieces of steel, the author feels that the real elastic limit is lower than that obtained by the drop of the beam. For this reason, many of the axles broke under conditions where they ran perhaps 8,000 to 15,000 miles. It is known that the first calculations were very nearly right, taking into account what might be called a normal elastic limit.

The author once made a test on a truck, driving down town with a pendulum bob in front of him, which was really a rough accelerometer. As the truck accelerated forward, the pendulum bob of course swung backwards and everything seemed to act quite normally until a policeman raised his hand and stopped the machine and then gave a signal to go across the street. The truck then accelerated forward, when suddenly a small machine ran out in front; the brakes were jammed on and the pendulum bob swung right across from backwards to forwards. Several tests were tried after that and the conclusion was reached that the stress on material subject to alternating stresses is not the stress based on what might be called the normal line, but is the summation of the two stresses, and the elastic limit based on this summation should be very much lower, how much lower he did not know exactly. Roughly speaking, the elastic limit is anything from about one-half to two-thirds of what it is thought to be.

Tests made on testing machines appear to be of exceedingly little value. This is perhaps rather a hard thing to say, but it is true, and it is no use making tests on a few specimens of meagre size when the material breaks down when it comes to the practical use of large quantities of full size. The author has come to the conclusion that the practical test is the only real test. All the theoretical tests, the Sankey bending machine tests, the Avery impact tests and the ordinary tensile tests show this high tensile steel actually was not as satisfactory as what engineers call tough material, that is, material of a lower elastic limit, with a higher elongation and higher contraction.

We are still trying to find laboratory machines which will tell us what stresses we actually get in trucks, but we haven't got them yet.

A COMPARISON OF THE PROPERTIES OF A NICKEL, CARBON AND MANGANESE STEEL BEFORE AND AFTER HEAT TREATMENT

BY ROBERT R. ABBOTT, CLEVELAND, O.

Non-Member¹

THE effect of small quantities of manganese upon the physical properties of annealed steel is fairly well known. Up to about 2 per cent, each 0.01 per cent of manganese increases the tensile strength by about 160 lb. per sq. in. Its effect upon the reduction in area and elongation is very small, slightly increasing the former and lowering the latter. From about 2½ to 7 per cent manganese makes steel extremely brittle, and above 7 per cent this effect disappears and we again have a useful alloy. An 11 per cent alloy has a wide range of use in the cast form for crossing frogs, rolls, gears, etc.; it is usually finished by grinding, as it is nearly impossible to machine.

We can classify the average commercial steels made in this country with carbon less than 0.50 per cent into those with manganese contents approximately (a) 0.40 to 0.50 per cent; this group includes the ordinary carbon steel and chrome-nickel steel, (b) 0.60 to 0.70 per cent; this group includes nickel and chrome-vanadium steels. This classification represents fairly well commercial practice; English steels fall readily into it, but with German steels the grouping is not so well defined. It is rare to find a steel in this country with manganese above 1 per cent (and below 2 per cent). Abroad, a considerable amount of steel is used, particularly for frames of automobiles, with manganese varying from 1.25 to 1.75 per cent.

Very little has been published regarding the heat treatment of these high manganese steels, and I am therefore presenting a comparison of the effect produced upon the physical properties of three steels of about the same carbon contents. One of these is a plain carbon steel, another a nickel steel, and the third a manganese steel, containing 1.61 per cent manganese. Their analysis is as follows:

	Carbon steel	Nickel steel	Manganese steel
Carbon	0.342	0.336	0.341
Phosphorus	0.014	0.019	0.047
Sulphur	0.029	0.019	0.025
Manganese	0.54	0.55	1.61
Silicon	0.030	0.188	0.009
Nickel	0.0	3.17	0.0
Chromium	0.0	0.0	0.0
Vanadium	0.0	0.0	0.0
Copper	0.0	0.05	0.02

In these three steels the upper critical temperatures were first determined. Test bars ¾ in. in diameter and 4½ in. long were next machined from each steel; one of each kind was annealed by heating in lead to a temperature 5 deg. Fahr. above the upper critical temperature, holding there

¹ Metallurgical Engineer, The Peerless Motor Car Co.

about ten minutes, and allowing to cool slowly until the lead solidified. The time of this cooling was about ten hours. The lead was then heated slowly to a temperature of 800 deg. Fahr. and the test bars removed. They were then threaded and machined to a standard 2 in. test specimen and ground to a diameter of 0.505 in. (1.5 sq. in.). One end was left longer than the other to allow for hardness tests. They were then pulled in a tensile machine with the following results:

Steel	Elastic	Maximum	Reduction	Elongation	Brinell hardness
Carbon	36,600	67,250	51.0	32.0	120
Nickel	55,000	81,850	59.0	31.2	153
Manganese	61,150	87,850	58.5	29.9	150

From these figures we see that the manganese steel is slightly stronger than the nickel steel, and has practically the same amount of "toughness" as shown by the reduction in area.

For the heat-treated specimens a test bar of the same size was used. The heating was all done in lead and was

FIG. 1 TESTS ON EFFECT OF HEAT TREATMENT ON MAXIMUM STRESS [UPPER CURVES] AND ELASTIC LIMIT [LOWER CURVES]

controlled by a Leeds & Northrup resistance pyrometer. The desired temperature was reached slowly and maintained as nearly constant as possible for ten minutes. All tests which were to be made at the same temperature were made simultaneously. The furnace contained half a ton of lead, and therefore the temperature could be kept very uniform. The bars were quenched in water and were drawn to the desired temperature in a lead furnace holding about three tons, all bars to be drawn at the same temperature being drawn simultaneously. The desired temperature was maintained constant for thirty minutes.

After treatment the bars were machined, ground to a diameter of 0.505 in., and pulled in a tensile machine having an autographic recording device. Hardness tests were made on the long end of the test bar after sawing off and

grinding to a flat surface. The following determinations were made: elastic limit; maximum strength; reduction in area; elongation; brinell hardness; scleroscope hardness; rupture stress; energy in foot pounds necessary to cause fracture. The last three determinations are not considered here. Test bars were treated from above the upper critical temperature and were then drawn to the following temperatures: 300, 500, 700, 800, 900, 1000, 1200, 1300 deg. Fahr.

In Figs. 1, 2 and 3 are plotted the results of these tests

FIG. 2 TESTS ON EFFECT OF HEAT TREATMENT ON REDUCTION IN AREA [UPPER CURVES] AND ELONGATION [LOWER CURVES]

for the three steels. From these charts it can be concluded that practically the same results can be obtained, as far as strength is concerned, by the heat treatment of a 1.6 per cent manganese steel as for a nickel steel of practically twice the per cent of nickel. However, since the nickel steel also contains 0.55 per cent manganese, we actually have an excess of only 1.06 per cent manganese, which apparently has the same effect as about three times the same amount of nickel.

Now, regarding the "toughness," which for the sake of comparison can be considered as being measured by the reduction in area, we see that the manganese steel does not compare so favorably with the carbon or nickel steel for the same temperature of draw. Evidently also, while manganese increases the reduction in area in annealed steels, it has the opposite effect in heat-treated steels.

The next determination was upon the effect of over- and under-heating during the quenching process. For this purpose ten bars of each steel were quenched as follows: One 5 deg. above the upper critical point, six others at 25, 50, 75, 100, 125 and 150 deg. above and three at 25, 50 and 75 deg. below the critical point. These were all drawn to a temperature of 800 deg. Fahr. and the regular tests conducted upon them. The results of these tests are plotted in Figs. 4 and 5. They show that there is very little difference between the nickel and manganese steels as far as over and under heating is concerned.

Summarizing, for a heat-treated 1.2 per cent manganese steel the manganese in excess of that contained in a nickel

steel of a corresponding carbon contents (about 0.34 per cent) exerts a strengthening effect equivalent to about three times the same amount of nickel. While the manganese

FIG. 3 TESTS ON EFFECT OF HEAT TREATMENT ON BRINELL HARDNESS

effect upon a steel which has not been heat-treated is to increase the toughness slightly, its effect upon a heat-treated steel is decidedly the reverse; in the case of nickel, the effect upon an untreated steel is practically zero, while in a heat treated steel nickel increases the toughness decidedly. An untreated steel containing about 1.2 per cent manganese is fully as tough as and is stronger than a nickel steel of about .34 per cent nickel.

The following equations represent fairly well the average

FIG. 4 TESTS ON EFFECT OF OVER- AND UNDER-HEATING ON MAXIMUM STRESS [UPPER CURVES] AND ELASTIC LIMIT [LOWER CURVES]

values of the elastic limits, maximum strengths, reduction in area and elongation of the three steels.

- E = elastic limit in pounds per square inch.
- M = maximum stress in pounds per square inch.
- r = reduction in area in per cent.
- e = elongation in per cent.
- T = temperature of draw in fahrenheit.

For manganese steel

$$\begin{aligned} E &= 284,000 - 163 T \\ M &= 288,000 - 159 T \\ r &= -19 + .068 T \\ e &= -10 + .028 T \end{aligned}$$

For nickel steel

$$\begin{aligned} E &= 302,000 - 183 T \\ M &= 314,000 - 188 T \\ r &= 40 + .024 T \\ e &= 3.5 + .018 T \end{aligned}$$

For carbon steel

$$\begin{aligned} E &= 134,000 - 66 T \\ M &= 170,000 - 77 T \\ r &= -5.8 + .063 T \\ e &= -3 + .026 T \end{aligned}$$

DISCUSSION

HENRY M. HOWE¹ (written): The manganese steel to which Mr. Abbott calls attention has come into use in this country more widely than might be inferred from his remarks. The late Maunsell White developed a steel of over

FIG. 5 TESTS ON EFFECT OF OVER- AND UNDER-HEATING ON REDUCTION IN AREA [UPPER CURVES] AND ELONGATION [LOWER CURVES]

1 per cent. manganese and somewhat lower in carbon than Mr. Abbott's, and this has gone into very wide use where high quality is needed.

Roughly speaking, 1 per cent of manganese is about equivalent to 2 per cent of nickel, at least 1 per cent of manganese accomplishes some of the more important things which double the quantity of nickel accomplishes.

The reason why manganese and nickel are useful for such steels is a very simple one. In order to develop the properties of a given steel very highly it should be heated above the transformation range, in order to cause the usual rather coarse masses of ferrite to become reabsorbed. The steel should then be cooled rapidly, lest in slow cooling through the transformation range the ferrite again should form coarse masses.

If this cooling is done by quenching in water or oil the resultant steel is too brittle; that is to say, the chemical trans-

¹ Columbia University, New York.

formation is arrested and at the same time serious internal stresses are set up. In order to permit the transformation to complete itself, so that the chemical brittleness may be removed, and in order to relieve the stresses which are also a cause of brittleness, the steel must next be reheated, as in tempering or moderate annealing. The rise of temperature enables the chemical transformation to complete itself, so that the metal becomes transformed into ferrite and cementite. It also releases the stresses. But this is accompanied by an incidental damage, namely that the resultant ferrite coalesces more and more into larger and larger masses, and with the increase in the size of these masses the quality of the steel falls off progressively.

The advantage of manganese and nickel is that they cause this coalescence and coarsening to occur very slowly. As a consequence, when the steel is reheated so that the transformation occurs, removing the chemical brittleness, and that the stresses are removed, thus removing the second cause of brittleness, the coalescence of the ferrite is very much slower than in steel with less manganese.

And in general this same sluggishizing effect of manganese and nickel under miscellaneous conditions gives rise to a finer structure than would otherwise form. Their effect in this respect is like that of vanadium, only less powerful.

ON MEASURING GAS WEIGHTS

BY THOMAS E. BUTTERFIELD, SOUTH BETHLEHEM,
PA.

Member of the Society

The author is interested in accurate methods of determining gas quantities, such as the quantity of gas delivered by a fan, a blower, or a compressor, or the quantity of gas generated by a producer, furnace or other combustion apparatus, or finally the quantity of gas used or consumed for various purposes.

In reporting results on gas measurement, the use of volume as an expression of quantity or mass should be eliminated. Gas quantities should be expressed by weight. Volumes of ordinary standard gases even at standard pressure and temperature are useful in determining quantities, but it is almost always misleading to use such volumes as measures of quantity or mass.

The name of a gas even to the engineer is no exact indication of its constitution or physical properties, because commercial gases made by the same process or indeed in the same apparatus are subject to important variations in the proportions of their principal constituents.

Density of a gas may be readily calculated from the chemical analysis, but the result of such calculation giving quantity in pounds should always be reported by the investigator. For fuel gases this would also imply that thermal quality be expressed in heat units per pound, and in general all volume data should be regarded as of only collateral interest.

It is usual to consider that after generation commercial gases retain their composition unaltered. Even gases containing no condensable fatty constituents, however, suffer

considerable changes in their moisture content with changing temperature, due to the corresponding change of vapor tension of steam. If a gas be used at the same temperature with different treatment after water contact or with no water contact, the moisture content will be quite different. The ordinary volumetric analysis gives the composition of the dry gas, which is different from the actual composition as generated or used.

Where accuracy is of importance the moisture content should be measured.

Gasometer measurements furnish the most accurate method of determining gas volumes and weights. It is essential that the temperature of the gas should be uniform in every part of the gasometer.

Displacement gas meters, whether of wet or dry type, are very accurate where the volume of the measuring chamber is unalterable or accurately known at every instant, and where the pressure, temperature and humidity of the gas at the instant of filling are also known, or nearly the same as at calibration. This is not true in fluctuating flow.

The pitot tube, venturi meter, and orifice methods of measurement depend for accuracy on the preservation of a constant relation of velocities over an entire cross-section, accurate measure of this cross-section, and accurate measurement of gas density. It is evidently as easy to calculate weights as volumes from the readings of such meters. They are not at all adapted to measure a rapidly fluctuating flow or a flow accompanied by eddies.

Where the specific heat of the gas is known its weight may be calculated by the change in temperature produced by the addition or abstraction of a known quantity of heat.

Where large volumes of gas are to be measured reliable shunt methods could be developed for measuring part of the flow, just as electric current is measured. A rational form for such a shunt would be a double walled diaphragm placed in the main through which the gas passes. The diaphragm is pierced full of holes all of the same size, say of about one inch diameter. From one in twenty to one in one hundred of these holes communicates with the interior of the diaphragm, the remainder pass through both walls, and are short, slightly flaring tubes with sharp edges. The gas from the interior of the diaphragm is carefully metered and returned to the main, and gives a measure of the total amount flowing. This method should give quite accurate results with either continuous or fluctuating flow.

Finally, we have methods which depend on chemical analysis of the gas and measurement of one constituent which forms a known percentage of the whole.

Various metallurgical formulae are in use for obtaining the result from volumetric analyses of fuel and burnt gas. It is the author's belief that the following method, based on reduction of volumetric analysis to weight analysis is simpler and safer than other methods, and the principal object of this paper is to urge its adoption in a standard code.

An example will illustrate the method. The fuel gas contains 2 per cent moisture. The volumetric analysis of dry fuel gas is $\text{CO} = 6$ per cent, $\text{CO}_2 = 2$ per cent, $\text{CH}_4 = 40$ per cent, $\text{C}_2\text{H}_2 = 4$ per cent, $\text{H}_2 = 46$ per cent, and $\text{N}_2 = 2$ per cent. After burning with air containing 11.2 per cent moisture the volumetric analysis of the dry products of combustion is

$\text{CO}_2 = 8.8$ per cent, $\text{O} = 4.5$ per cent, and $\text{N}_2 = 86.7$ per cent.

It is required to find the ratio by weight or volume of the burnt gas to fuel gas. Call this ratio a_w for weight, or a_v for volume. Then, necessarily, the weight of air is $a_w - 1$, if fuel gas weight be taken as unity.

The four elements, carbon, hydrogen, oxygen and nitrogen are the only ones present in the three gases, and the volumetric analyses are reduced to weight analyses giving proportions of these four elements. The actual volumetric analysis of the fuel gas including moisture is

Constituents CO CO₂ CH₄ C₂H₆ H₂ N₂ H₂O
Per cent 5.9 2 39.2 3.9 45 2 2
The total carbon weight is

$$12 (5.9 + 2 + 39.2 + 2 \times 3.9) = 659.$$

The hydrogen weight is

$$1 (4 \times 39.2 + 4 \times 3.9 + 2 \times 45 + 2 \times 2) = 268.$$

The oxygen weight is

$$16 (5.9 + 2 \times 2 + 2) = 190.$$

The nitrogen weight is

$$28 \times 2 = 56.$$

The density of the gas is

$$\frac{659 + 268 + 190 + 56}{200} = \frac{1173}{200} = 5.86 \text{ times that of hydrogen.}$$

The weight analysis by elements is: carbon = $\frac{659}{1173}$, hydrogen

$$= \frac{268}{1173}, \text{ oxygen} = \frac{190}{1173} \text{ and nitrogen} = \frac{56}{1173}, \text{ or in per cent}$$

C₁ = 56.1 per cent, H₁ = 22.9 per cent, O₁ = 16.2 per cent, and N₁ = 4.8 per cent, using the subscript "one" to denote fuel.¹

Similarly the weight analysis of air is: H₂ = 0.1 per cent, O₂ = 24 per cent, and N₂ = 75.9 per cent, with a density = 14.34 times that of hydrogen. We use subscript "two" to denote air.

The weight analysis of the "dry" products of combustion is: C₃₀ = 3.6 per cent, O₃₀ = 14.4 per cent, N₃₀ = 82 per cent and the density is 14.8 times that of hydrogen. We use subscript "30" to denote "dry" products of combustion.

The weight of any element in the burnt gas (before condensation of moisture) is the sum of the weights in fuel gas and air, giving rise to the four fundamental equations:

$$C_1 + (a_w - 1) C_2 = a_w C_3, \text{ carbon equation} \dots\dots\dots [1]$$

$$H_1 + (a_w - 1) H_2 = a_w H_3, \text{ hydrogen equation} \dots\dots\dots [2]$$

$$O_1 + (a_w - 1) O_2 = a_w O_3, \text{ oxygen equation} \dots\dots\dots [3]$$

$$N_1 + (a_w - 1) N_2 = a_w N_3, \text{ nitrogen equation} \dots\dots\dots [4]$$

Since the weight of carbon in air is negligible

$$C_1 = a_w C_3, \text{ or } a_w = \frac{C_1}{C_3} \dots\dots\dots [5]$$

Since the relative proportions of carbon and nitrogen in the burnt gas cannot be altered by the separation of moisture, we may write

$$\frac{\text{carbon in fuel plus carbon in air}}{\text{nitrogen in fuel plus nitrogen in air}} = \frac{\text{carbon in dry burnt gas}}{\text{nitrogen in dry burnt gas}}$$

or

$$\frac{C_1 + (a_w - 1) C_2}{N_1 + (a_w - 1) N_2} = \frac{a_w C_3}{a_w N_3} = \frac{a_w C_{30}}{a_w N_{30}}$$

Simplifying

¹ In the equations which follow, the numerical subscripts do not indicate numbers of atoms.

$$\frac{C_1}{N_1 + (a_w - 1) N_2} = \frac{C_{30}}{N_{30}}, \text{ and } a_w = 1 + \frac{C_1 N_{30} - N_1 C_{30}}{N_2 C_{30}} \dots\dots [6]$$

Equation [6] gives a simple expression for the weight ratio from the analyses by weight of fuel and "dry" burnt gas. The weight of moisture in the burnt gas is nine times the total weight of hydrogen in fuel and air, or

$$9 \{ H_1 + (a_w - 1) H_2 \}$$

and the weight of "dry" burnt gas per pound of fuel is

$$a_w - 9 \{ H_1 + (a_w - 1) H_2 \}.$$

Then

$$\frac{C_3}{C_{30}} = \frac{N_3}{N_{30}} = \frac{a_w - 9 \{ H_1 + (a_w - 1) H_2 \}}{a_w}$$

and

$$C_1 = a_w C_3 = [a_w - 9 \{ H_1 + (a_w - 1) H_2 \}] C_{30} \text{ and } a_w = \frac{C_1 + 9 \{ H_1 - H_2 \} C_{30}}{(1 - 9 H_2) C_{30}} \dots\dots\dots [5a]$$

Similarly for nitrogen

$$N_1 + (a_w - 1) N_2 = [a_w - 9 \{ H_1 + (a_w - 1) H_2 \}] N_{30} \text{ and}$$

$$a_w = \frac{N_2 - N_1 - 9 \{ H_1 - H_2 \} N_{30}}{N_2 - N_{30} (1 - 9 H_2)} \dots\dots\dots [4a]$$

The oxygen in fuel and fuel less the oxygen that separates from the burnt gas as moisture is equal to the oxygen in the "dry" burnt gas, or

$$O_1 + (a_w - 1) O_2 - 8 \{ H_1 + (a_w - 1) H_2 \} = [a_w - 9 \{ H_1 + (a_w - 1) H_2 \}] O_{30}$$

or

$$a_w = \frac{O_2 - O_1 + (8 - 9 O_{30}) (H_1 - H_2)}{O_2 - 8 H_2 - O_{30} (1 - 9 H_2)} \dots\dots\dots [3a]$$

Applying equations [3a], [4a], [5a] and [6] to the solution of the problem given we use the recapitulation of analyses by weight.

	Fuel	Air	Dry burnt gas
O	16.2	24	14.4
N	4.8	75.9	82
H	22.9	0.1	
C	56.1		3.6
Density	5.86	14.34	14.8

Then from [3a]

$$a_w = \frac{O_2 - O_1 + (8 - 9 O_{30}) (H_1 - H_2)}{O_2 - 8 H_2 - O_{30} (1 - 9 H_2)} = \frac{0.24 - 0.162 + (8 - 9 \times 0.144) (0.229 - 0.001)}{0.24 - 8 \times 0.001 - 0.144 (1 - 9 \times 0.001)} = 18.05$$

From [4a]

$$a_w = \frac{N_2 - N_1 - 9 (H_1 - H_2) N_{30}}{N_2 - N_{30} (1 - 9 H_2)} = \frac{0.759 - 0.048 - 9 (0.229 - 0.001) 0.82}{0.759 - 0.82 (1 - 9 \times 0.001)} = 18.13$$

From [5a]

$$a_w = \frac{C_1 + 9 (H_1 - H_2) C_{30}}{(1 - 9 H_2) C_{30}} = \frac{0.561 + 9 (0.229 - 0.001) 0.036}{(1 - 9 \times 0.001) 0.036} = 17.79$$

From [6]

$$a_w = \frac{C_1 N_{30} - N_1 C_{30}}{N_2 C_{30}} = 1 + \frac{0.561 \times 0.82 - 0.048 \times 0.036}{0.759 \times 0.036} = 17.79$$

$$\text{The percentage error} = \frac{18.13 - 17.79}{18.13} \times 100 = 1.9. \text{ The error evidently lies in the too rough approximation in de-}$$

termining $C_p = 0.036$. The value of the check given by the separate determinations is evident. The author has had this method in use for some years with very satisfactory results.

The author has been requested to give reasons why gas quantities should be expressed in weight rather than by volume. There are two very important reasons.

First. If gas quantity is expressed in pounds we have the simplest possible unit. Erroneous statements of weight will not often be made and are easily checked. On the other hand, if quantities are expressed by volume, we must give volume, temperature and pressure both under observed conditions and reduced to some standard pressure and temperature. There is considerable probability of errors in neglecting or forgetting to reduce volume to standard conditions, or in neglecting to state the conditions assumed standard. Further, weight makes an immensely stronger appeal to the senses than volume. This in itself makes it harder for the writer to make errors and easier for the reader to detect errors and comprehend results.

Second. The value of a definite gas in the various industries is determined by its weight rather than by its volume. For instance, in furnace work, it is necessary to furnish a certain weight of air to consume the fuel. In measuring the output of a compressor, it is important to know the number of pounds of air delivered against the discharge pressure. The capacity of an air pump is determined by the number of pounds of air it can remove from a certain vacuum. The capacity of a gas engine is determined by the number of pounds of air and fuel it can draw into the cylinder. In all of these cases the volume is of subordinate interest. Comparison on the basis of volumes is misleading.

In a combustion process involving solids or liquids and gases the custom of giving fuel quantities in pounds and air and gas quantities in cubic feet is not conducive to clear thinking. Imagine an investigator stating that a certain number of cubic feet of coal was charged into a furnace! Of course weight of gas cannot be determined ordinarily without calculation. But the calculation involved is not greater than that required to put volume readings in form permitting definite and precise understanding of results.

In reference to the illustrative example given, the author wishes to state that, in his method of calculating the weights of air and burnt gas from a known fuel weight, simple weight calculations are used and combustion formulae are not used. This is the distinguishing feature of the method. The number of pounds of any element entering a reaction must be the same as the weight leaving. Equations 1 to 4, contain all the fundamental equations, following which the modifications required are shown when the complete analysis of burnt gas, including moisture, is not known. When weight ratio is known, as air, volume ratio can be easily found by dividing by density ratio.

DISCUSSION

ARTHUR M. GREENE, JR., suggested that if the equations or methods given by the author were to be adopted, it would be better if the nomenclature were changed so that the literal values were more suggestive of the things for which they actually stood. One of the great faults in connection with equations is that literal values are so formed as to suggest something entirely different from the things for which they stand.

THE USE OF CORRUGATED FURNACES FOR VERTICAL FIRE TUBE BOILERS

BY F. W. DEAN, BOSTON, MASS.

Member of the Society

I HAVE been impressed for many years with the value of corrugated furnaces for vertical boilers, but only recently have actually used them. By their use staybolts are

FIG. 1. VERTICAL BOILER WITH CORRUGATED FURNACE

done away with, and as there appear to be no disadvantages in the furnace this is a most important feature. As many hundreds of staybolts are avoided in each boiler, there are

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion; price 5 cents to members; 10 cents to non-members.

just so many less opportunities for breakage and needed repairs.

This type provides for expansion and contraction of the tubes in a safe manner, but on account of its somewhat flexible character it should be assumed that it is advisable to support the lower tube plate as near the edge as practicable. The ordinary firebox is rigid vertically and supports the edge of the lower tube plate, but as the corrugated firebox has slight elasticity it is best to hold up as much of the tube plate as practicable by the tubes and provide little or no elasticity in the tube plates. The flat and unstayed portions of the upper and lower tube plates should be made equal in diameter in order to balance.

The behavior of the firebox end of the boiler when under pressure led to some speculation, for the area of the fire door opening theoretically unbalances it. When under hydrostatic pressure, various gauges were used for showing distortion, but none could be discovered.

In regard to sizes of such furnaces the catalogue of the American maker gives 60 in. as the maximum inside diameter, but in fact this company can make them up to 72 in., and almost 1 in. thick. They have been made slightly larger in Germany and the furnace of the boiler illustrated was obtained in that country. If the inside diameter is 72 in., the grate will be 3 in. larger or 75 in. and the grate area 30.68 sq. ft. It is easy enough to generate 200 h.p. on a grate of this size with considerable capacity for forcing beyond this, and there is no difficulty in providing the heating surface for this horsepower.

In regard to pressure, a furnace 72 in. in diameter and 0.95 in. thick will carry 200 lb. If there were sufficient demand for larger furnaces they would probably be forthcoming. The theory of heat transmission through plates, and experience, show that thick furnaces, especially if without riveted joints, are unobjectionable.

The introduction of corrugated furnaces for the fireboxes of the vertical type of boiler is, I think, a real improvement in steam boilers. The type possesses the important qualities of giving maximum and permanent economy, superheating the steam from 20 deg. to 40 deg., being free from brickwork and requiring small floor space per horsepower.

DISCUSSION

W. F. MACGREGOR (written). In contemplating a change in any well known type of construction, it is natural to consider first the effect on that portion which experience has shown to have given the most trouble. This in vertical fire-tube boilers is tube leakage at the crown sheet. Our first question is, then, Will a flexible furnace tend to increase or diminish tube leakage, granting that the corrugated furnace is more flexible?

When the first Manning boilers were built, it was thought necessary to provide for the differential expansion between the tubes and shell, and an attempt was made to do so in the O. G. ring, but it was found to be impracticable. The amount of differential expansion cannot be great, and it is questionable if the tubes acting through the medium of the flexible crown sheet can produce a change in length of the corrugated furnace. On the other hand, it is possible to imagine that the corrugated furnace may gradually change in length and tend to produce tube leakage. As to whether the tube leakage will be greater or less with a corrugated furnace can only be shown by experience.

But the principal point in considering any new boiler construction is safety. Before abandoning the stay-bolted construction for other types we should bear in mind its good points as well as the bad ones. The stay-bolted surface is increased in strength by a slight deformation or bulging of the plates, while the corrugated furnace is weakened by any deformation, especially if local in character. Leakage at stay-bolts or a slight bulging of the plates, is sometimes a "blessing in disguise," in giving warning of conditions in the boiler that should be corrected in good time to avoid serious damage or disaster. Broken stay-bolts in stationary boilers are so common as to condemn this type of construction, but when provided with tell-tale holes they do not constitute a source of danger.

After considering safety, durability, efficiency and convenience, we must also take into account the cost of construction, and while the figures showing the cost of the corrugated furnace are not at hand, I believe it is more expensive than the other type. The most apparent advantages of the corrugated furnace in the vertical fire-tube boiler are the decreased resistance to circulation and the increased facilities for cleaning.

H. WADE HIBBARD objected to the staying of the top tube sheet of the boiler shown in the figure. He referred to the statements of the author that this particular boiler will carry 300 lb. pressure and that the steam is superheated to as high as 40 deg. superheat. The temperature at the top of the diagonal stay for the tube top-sheet must be very much higher than the temperature of the superheated steam, which means that the top foot of the diagonal stay must certainly be at the temperature of blue heat. It is a well known fact, established by tests and experience, that in the blue heat region iron and steel are brittle; and if bent within the blue heat zone are far more liable to crack than if at a higher temperature or at a lower temperature. As the pressure in the boiler changes, the diagonal stay will be constantly subjected to bending action and there will be danger of the diagonal stay breaking at its bend.

ARTHUR M. GREENE, JR. If we look sideways at the illustration of this boiler, we have practically a locomotive type boiler, especially if we put the firebox a little eccentric, and I would like to ask the author if he could include in his paper, in the discussion or the closure, some facts as regards the action of the Vanderbilt firebox in locomotive boilers, because the experience of the railroad people with that type of boiler, especially in the firebox end, would be of great value to members of this Society if they should consider the adoption of Mr. Dean's form of boiler.

FORREST E. CARDULLO. I agree with Professor Greene with regard to the safety of the general form of design, and also with Professor Hibbard as regards the diagonal stay, but that matter might be very easily taken care of by carrying the boiler, in a conical form, from the joint flush with the crown sheet of the firebox up to the upper tube sheet, so as to eliminate entirely the necessity of staying that part of the boiler.

I see no reason why anyone should build a 200 h.p. vertical tubular boiler. Such a boiler, in my experience, invariably causes stack temperatures of 800 or 1000 deg., which means that it is inherently a wasteful form of apparatus, unless provision is made for utilizing the waste heat.

THE EFFECT OF RELATIVE HUMIDITY ON AN OAK TANNED LEATHER BELT

BY WILLIAM W. BIRD, WORCESTER, MASS.

Member of the Society

AND FRANCIS W. ROYS, WORCESTER, MASS.

Non-Member¹

IT has long been a recognized fact that the weather has a more or less noticeable effect on leather belts. In experimental work it has often been found impossible to duplicate results when testing the same belt on different days. In

was changed. Thus the field being narrowed to these limited conditions of constant initial length, width, thickness and speed of the belt; diameters of the pulleys; horse power transmitted, and temperature, the investigation was carried out to determine:

- a. The effect produced on the center distance by varying the sum of the tensions, the relative humidity remaining constant.
- b. The effect of the relative humidity on the center distance, the sum of the tensions remaining constant.
- c. The effect of the relative humidity on the sum of the tensions, the center distance remaining constant.

FIG. 1. GENERAL LAYOUT OF THE APPARATUS

practice, those who are familiar with the behavior of leather belts have noticed a difference in the action of belts from day to day, under varying conditions of the weather. However, when the generally accepted rules for belting are consulted, it will be found that the discussion of the weather has been entirely omitted for once. Of the several weather conditions which can be noted readily, it was thought that the variation of the relative humidity of the atmosphere would offer the most promising field and therefore the effect of this variation was chosen as the subject for a special investigation.

The most noticeable effect of an increase in the humidity was found to be in the lengthening of the belt. If the distance between the pulley centers remained constant, this lengthening of the belt would decrease the sum of the tensions. On the other hand, the sum of the tensions could be maintained by varying the center distance as the humidity

A general layout of the apparatus used in these experiments, which were conducted at the Worcester Polytechnic Institute, is shown in Fig. 1. It may be described as follows:

A shaft which carries a pulley on one end and an Alden dynamometer on the other is mounted on a carriage which is free to move in a horizontal direction at right angles to the shaft. On the same level with this first shaft and parallel to it, is a jack shaft driven at constant speed. This jack shaft has a pulley on one end the same size as the pulley on the dynamometer shaft and the "belt under test" runs over these two pulleys. The Alden dynamometer furnishes the load, which is equivalent to $T_1 - T$ or the difference between the tensions of the tight and slack sides, and the platform scales weighs the sum of the belt tensions or $T_1 + T_2$, as shown in the figure.

In order to measure all of the power transmitted by the belt, the shaft bearings were so designed that they formed a part of the dynamometer. Fig. 2 shows this arrangement in more detail. The bearings consist of pairs of S. K. F. ball bearings in which the shaft turns. The ball bearings are carried in a housing which is free to turn inside of a

¹ Worcester Poly. Inst.

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discount; price 5 cents to members; 10 cents to non-members.

pair of Standard roller bearings. Thus what little friction there may be in the ball bearings will tend to turn the housing which is attached to the dynamometer casing and thereby becomes a part of it.

In the rear of the room, Fig. 1, is a Sturtevant heater and blower, the heater to keep the temperature under control and the blower to circulate the air in the room. A live steam jet inside the heater was used for humidity control. The degree of relative humidity was measured by a precision hygrometer of the hair type, a wet and dry bulb thermometer and a sling psychrometer, a modification of the pattern developed by the U. S. Weather Bureau, the last method giving very satisfactory results.

The belt used in this investigation was a four-inch, single, oak tanned leather belt furnished by the Graton & Knight Mfg. Co. of Worcester. The pulleys were a pair of cast iron crown face pulleys, twenty-four inches in diameter with a six inch face. The initial length of the belt was such that the center distance at 20 per cent humidity, $T_1 + T_2$, equaling 320 lb., was 9 ft. 6 $\frac{3}{4}$ in.; this makes the belt approximately 25 $\frac{1}{2}$ ft. long. Standard conditions were assumed to be $T_1 = 240$, or 60 lb. per in. of width, and $T_2/T_1 = 3$, where T_1 is the tension in the tight side of the belt and T_2 the tension in the slack side; this gives $T_1 - T_2 = 160$ lb. and as the belt speed remained constant at about 1900 ft. per minute, the horse power was approximately 9.21 all of the time. The slip was between 0.8 and 0.9 of one per cent.

Experiments were run to see if a difference in the modulus of elasticity of the belt, when running, could be detected at 20 per cent, 55 per cent and 90 per cent humidity. Tests were also made at these humidities to see if a difference in the slip due to different values of the modulus of elasticity could be shown. No noticeable effect could be detected. The results are plotted as curves in Figs. 3 and 4, and as a surface in Fig. 5.

The three black spots indicated on the surface of Fig. 5 all occur at $T_1 + T_2 = 320$ lb. Now starting at any one of these points and keeping the center distance constant, take the course indicated by the line along which the printing occurs. This line is seen to cross the lines of constant tension, the tension increasing as the relative humidity decreases, or vice versa.

The surface shown in Fig. 5 might well be called the characteristic of this belt, and it indicates in a general way what might be expected from similar belts. Leather itself will vary; the tanning is different; the quantity and quality of belt dressing is never twice the same. All of the factors being more or less unknown, it will be impossible to make definite prediction regarding other belts.

However, in a general way, it may be stated that the effect of a change in relative humidity is greater at high humidities than at low, that the effect is shown more rapidly in a single than in a double belt, and that increasing the humidity shows immediate results while a decrease in humidity takes some little time to be effective.

Curves are given in the paper, derived from Fig. 5 and illustrating, for belts set up at various humidities, the effect of changes in the humidity on the ratio of the tensions. Two of these relations are shown in Fig. 6, for a standard set-up of 55 per cent relative humidity, which is near the normal, and a change in relative humidity will not produce either an excessive ratio of tensions or an undue sum of tensions.

As the higher relative humidities generally occur at temperatures above 70 deg., a series of experiments was run at 50 deg. temperature with the relative humidity varying from 20 per cent to 90 per cent, and another series at 90 deg. temperature, $T_1 + T_2$ and h.p. being constant for all of these tests. These results are shown in Fig. 7, which also has the corresponding results at 70 deg. from previous experiments. This would indicate that the belt lengthens as the temperature increases, the relative humidity remaining constant; that the amount of this lengthening is somewhat greater at high relative humidities than at low relative humidities; and that the lengthening due to an increase in the relative humidity is greater at temperatures higher than 70 deg. and less for temperatures under 70 deg.

It would appear from the experiments that the lengthening

FIG. 2 DETAIL VIEW OF THE DYNAMOMETER

of the belt which takes place when the humidity increases is very nearly proportional to the relative humidity, while no definite relation to absolute humidity exists. The fact that the lines in Fig. 7 are not parallel would indicate that either there is some slight effect due to changes in the absolute humidity or, what is more probable, that the coefficient of expansion is greater at 90 deg. than at 20 deg. temperature.

The general conclusions are:

First. If a belt be set up at low relative humidity, slipping will probably occur if the relative humidity increases to any great extent, especially if accompanied by a rise in temperature.

Second. If a belt be set up at high relative humidity, excessive pressure on the bearings and stretching of the belt will result from a decided decrease in relative humidity, especially if accompanied by a fall in temperature.

Third. If a belt be set up at a medium relative humidity, the tensions will not be excessive at lower relative humidities, nor will there be any great danger of slipping at high relative humidities unless accompanied by excessive temperature changes, in other words, the factor of safety in the ordinary belt rules is sufficient to take care of the effect of

changes in the relative humidity if the set up be made at a medium per cent of relative humidity.

Fourth. If a belt be set up at any relative humidity with a spring or gravity tightener, a load 50 per cent greater than

real explanation of the matter in the disregard of these two points. It is very common to take up belts at night or on Sunday. During the winter time the temperature and relative humidity are very apt to be markedly different from those during regular working hours.

The results also show the advantage of more frequent use of belt tighteners. The highest efficiency of drive and the maximum life of the belt can only be secured by keeping the slack side tension as low as possible. The injury to the belt by bending it in the reverse direction as it goes around the tightener pulley is practically negligible if the pulley is made of large diameter; in fact, this loss and that due to the friction of the tightener is far less than that due to the extra load on the bearings of the main shafts due to the belt without a tightener never being at its condition of minimum stress

FIG. 3 RELATION BETWEEN $T_1 + T_2$ AND CENTER DISTANCE AT THREE CONDITIONS OF RELATIVE HUMIDITY. HORSE POWER CONSTANT

FIG. 4 RELATION BETWEEN PER CENT RELATIVE HUMIDITY AND CENTER DISTANCE AT THREE CONDITIONS OF $T_1 + T_2$. HORSE POWER CONSTANT

the standard can be transmitted at either high or low humidity without danger of stretching the belt, shipping or excessive pressure on the bearings.

DISCUSSION

GEO. N. VAN DERHOEF (written). This paper is very interesting as it goes far in explaining some of the peculiar actions of belt drives, and it is to be hoped that it will attract general attention to the subject of belt tensions. It is strange that, in all the experimental work that has been done from time to time on the transmission of power by leather belts, this feature of effect of humidity should not have been investigated before.

The results again show the importance of using spring belt clamps in tightening belts, and also that when these are used attention should be given to temperature and relative humidity. It is quite likely that those who have not found the use of spring belt clamps all they expected may find the

FIG. 5 BELT PERFORMANCE SURFACE FOR AN OAK TANNED LEATHER BELT 4 IN. WIDE, SHOWING RELATION BETWEEN CENTER DISTANCE, SUM OF TENSIONS AND PER CENT RELATIVE HUMIDITY

except just before taking up. A belt tightener is, however, of little value unless it is used to keep the belt just as loose as possible; it is very unfortunate that this important device was given the name of "tightener" instead of "loosener."

Nearly all belted electric generators and motors are arranged with sliding bases, and the belts used with them are considerably smaller than would generally be used with equal loads for other machinery.

The great success of the continuous system of rope transmission is due very largely to the fact that the tension can be kept at a minimum by means of the automatic tension carriage. While it is impossible to secure as favorable results with a belt drive, they can frequently be more or less approximated by the intelligent use of belt tighteners.

CARL G. BARTH wrote that some fifteen years ago, while working for the Bethlehem Steel Company, he attempted to study the influence of humidity on the tensions of two belts in the shop, by daily plotting simultaneous humidity readings and readings of belt tension scales applied to the belts. However, due to the unlooked-for extraordinary variations in the

loads transmitted by these belts (at times they would carry heavy loads and again they would run idle for days at a time), no definite results were obtained, whereas he could not help believe that results of some value would have been secured if the belts had transmitted a fairly uniform load day and night.

Previously, the drop in tensions of two other belts had been studied during the winter months, when the shop was

FIG. 6 EFFECT OF CHANGE OF HUMIDITY FROM 55 PER CENT. HORSE POWER CONSTANT

heated and both the temperature and the humidity thus kept within fairly small limits of variation. The results¹ were very satisfactory when the crudeness of the scales used was considered. The belts were re-tightened to a maximum tension when this had fallen to a minimum, which was carefully watched for by a system of inspection controlled by a tickler. A weakness in this has also been that on damp days old belts sometimes, and new belts frequently, reach the minimum tension between inspections, and thus at times require re-tightening during working hours, which is the very thing it was striven to avoid.

While the prescribed tension is so moderate that its rise due to a sudden drop in the humidity obtaining at a re-tightening will not do any great harm when the shaft and its bearings are properly proportioned and constructed, still it always appeared to him that some allowance should be made for the humidity, and he was of the opinion that the results obtained by the present experimenters would prove of value. However, he believed the results could be more readily applied if the experiments were repeated along the following slightly different lines:

Take a brand new first class belt and put it under an initial tension of 240 lbs. per square inch of cross section, over revolving pulleys transmitting no power. Measure its length under this tension while the humidity is kept constant. Keep this up until the tension has fallen to 120 lbs., or one-half the original amount. Re-tighten the belt over the same pulleys to 240 lbs. by cutting out the necessary fraction of its length, note this length, and proceed as before; repeat this procedure for at least one school year.

During the next two school years, repeat the process under different degrees of humidity, and with belts of the same

size and make and preferably cut from the same roll as the first, or, if this is not feasible on account of expense, build and equip three separate rooms for the purpose and do all the work in one year.

Next, thoroughly impregnate the belts with some good belt dressing, such as Kling-Surface or Plomo, and repeat the experiments. It is claimed, and it is undoubtedly true, that belt dressings keep out the moisture to a considerable extent.

He was sure that the results to be obtained by a constant length of the belt under no load transmission would be more readily applicable in practice than would the results obtained by a constant load transmission with variable belt length.

F. G. GILBRETH thought we paid too much attention to the cost of the belt; it is to the cost of the up-keep of the belt and its effect on the achievement of the task of the worker that we should look, and he would like to know the effects of these experiments if carried on in practice on those two features.

WM. S. ALDRICH (written). Considering the number of variables and the atmospheric conditions to be controlled,

FIG. 7 RELATION BETWEEN CENTER DISTANCE AND RELATIVE HUMIDITY OF THREE DIFFERENT TEMPERATURES

the results are well worthy of attention in the every-day use of belting. Especially will this attention be possible in factories having heating and humidifying systems under more or less automatic control. The factors of temperature and humidity have already been found to influence shop production, and the cost of regulating them is more than compensated in certain lines and developments through increased economy and efficiency, and the enhanced general welfare of the workmen.

Setting up the belt, therefore, under the standard and maintained temperature and humidity of the shop, may come to be the order of the day. The 55 per cent relative humidity chosen by the authors for their standard test comparisons seems reasonable, but the 70 deg. temperature chosen as an accompanying standard shop temperature would be uncomfortable in practice. The best working temperature is still a mooted question and depends on the class of workmen, the kind of physical work and the humidity. The best range is probably a little under or over 60 deg., according to local circumstances. 60 or 62 deg. is also about the standard normal temperature for comparisons of engineering data, in English measures.

The barometric pressure must be taken into consideration in standardizing atmospheric conditions with regard to the

¹ Transmission of Power by Leather Belting, Barth, Trans. A. S. M. E., vol. 31, p. 43.

relative and absolute amount of moisture present. It is not unusual for this to range over two inches of mercury in the course of a day in very changeable weather. Were barometric readings taken throughout and all observations reduced to standards of comparison for the conditioned relative humidity selected?

A careful study of the comparative results at different temperatures, illustrated in Fig. 7, will show that it is probably the actual amount of moisture present in the air which most influences the stretch of the belt, and this is, therefore, the determining factor. In the diagrams, the scale values of the relative humidity may be interpreted as directly proportional to the actual moisture, assuming, however, that the barometric pressure was constant throughout the test.

From Meteorological Tables¹, the absolute amount of moisture present in the air under standard conditions, is:

Deg. Fahr.....	50	70	90
Gr. Troy.....	4.076	7.980	14.780

In other words, at the standard conditioning of the air in the shop of 55 per cent relative humidity, the actual moisture in the air, at the above temperatures will be 2.24, 4.39 and 8.13 grains, respectively. These weights are not quite in geometric progression, but they are sufficiently cumulative to suggest interesting comparisons. They show to what extent the belt can absorb moisture as the temperature rises—how hygroscopic it really is. In short, the belt seems to have almost unlimited capacity to absorb moisture as the temperature of the air rises, and in comparison with the accompanying equal increments of belt stretch under test.

The authors have well pointed out that the difficulties inherent with so many variables as naturally arise in belt testing indicated constant speed and constant load as prerequisites. It would be interesting to know how these latter might vary under varying humidity with constant center distance. It is this latter condition which is imposed on the belt in actual service. For precise work in certain driving operations, it may even be desirable to go to the expense of waterproofing the belt if this should prove feasible.

A. F. NAGLE (written). This is a laboratory experiment and as such has an educational value, but its practical value may be questioned. Practical considerations, that is, men and materials, do not admit of too great refinements. Belt tensions should be adjusted by a mechanical engineer, with spring scales to guide him; but the operating mechanic will cut out an inch, more or less, if he finds a belt does not drive his machine. When the works are large enough to employ special men to attend all belts, something like the refinements alluded to in this paper may be carried out, but even then the practice is liable to fall into disuse.

The author should give the actual thickness of the belt used. Single thickness is not specific enough, for belts in the market vary nearly two to one in thickness.

W. W. BIRD replied that if a belt is fitted up with a spring or gravity tightener, it practically adjusts itself, and a very material difference is made in regard to the up-keep. He was running a great many machines with an idler or spring arrangement to take up and tighten the belt, and this is done automatically; the arrangement not only lengthens the life of the belt, but also has a bearing on the question of up-keep. The question of a few dollars for a belt is nothing in comparison with the loss of use of a machine.

LAPS AND LAPPING

BY W. A. KNIGHT, COLUMBUS, O.

Member of the Society

AND A. A. CASE, COLUMBUS, O.

Non-Member¹

THE process of working down a surface by lapping, that is by wearing it down by the use of a loose-grained abrasive in connection with a lubricant was first applied in the grinding and polishing of precious stones. Later the process was applied to the working of hardened steel, and, from this, gradually extended to cover a wide variety of operations common to machine-shop practice.

There are two methods of using a surface lap which, for want of better definitions, will be termed the "wet" and the "dry" methods. In the wet method there is a surplus of oil and abrasive on the surface of the lap.

With the dry method, the lap is first charged by rubbing or rolling the abrasive into its surface. All surplus oil and abrasive is then washed off, leaving a clean surface, but one that has embedded uniformly over it small particles of the abrasive. It is then like the surface of a very fine file or oil stone and will cut away hardened steel that is rubbed over it.

The lubricants most commonly used for lapping are lard and machine oils, kerosene, and gasoline. Alcohol and turpentine have been recommended. It is well known that turpentine can be used to advantage when drilling hard steel.

Abrasive materials are usually emery, alundum, corundum, carborundum, or others of a similar kind, but sold under various trade names, as Crystolon, Axolite, Carbon-dite, etc. Diamond dust, ground glass, oil stone powder, and ground pumice stone are used for certain kinds of work.

The object of the experiments described was to secure, if possible, reliable data on:

- The relative efficiencies of the different abrasives.
- The relative efficiencies of different lubricants.
- The rate of cutting with laps made of cast iron, soft steel, and copper.
- The wear of the laps, compared one with the other and with the amount of steel ground off with each.
- The effect of pressure on the rate of cutting.
- The rate of cutting by the wet and the dry methods.

To carry out the experiments, a machine was constructed with which quantitative results could be obtained with various combinations of abrasive, lubricant and lap material.

The usual method was followed of keeping all variables constant except one, and, having determined the effect of that one, to proceed to the next. It developed, however, that some of the variables affecting the results were not entirely within control. Thus, for instance, the size of the grains of abrasives is one of the factors affecting the rate of cutting, and this factor is continually changing during the process.

Again, when using volatile liquids, like gasoline, turpentine, and alcohol, fresh additions had to be made to the plate to make up the loss from evaporation.

¹ Instructor, Ohio State Univ.

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion; price 15 cents to members; 30 cents to non-members.

¹ Smithsonian Institution, Washington, D. C.

Thorough precaution was taken to reduce all uncertain factors to the lowest possible limit and confidence is felt that the results are well within the limits of practical accuracy.

The machine which was designed and used for these tests is shown in Fig. 1. The horizontal shaft *B*, driven by motor *A*, transmits motion through spiral gears to two vertical shafts *C* and *D*. Shaft *C* carries the lapping plate at its upper end and shaft *D* the slotted crank disk *E*, by means of which, and the connecting rod *F*, the specimen holder *H*

in the tube. At *k* is a hardened steel plug, which is also a smooth working fit in the tube. This plug has a conical seat at each end in which bear the tapered ends of screw *s* and pin *j*. A perfectly free vertical motion is obtained, whereby the weights can follow up the wear of the specimen with practically no friction.

The bushing *o* which carries the specimen is counterbored in order that any side thrust may be brought as near the lower surface of the specimen as possible. To move the specimen from under the tube for examination, or removal,

FIG. 1 SIDE ELEVATION OF MACHINE

is made to reciprocate between the center and outer edge of the lapping plate. The motions of the lapping plate and specimen holder cause the latter and its specimen to follow a path relative to the plate like that shown in Fig. 2.

As at first constructed the machine was autographic, but too many uncertainties were introduced by the friction of the pencil and other conditions and this feature was finally abandoned.

The specimen holder is shown in section in Fig. 3. The specimen is held in the hardened steel bushing *o* in end of lever *l*, which receives its motion through connecting rod *f* to which it is attached by studs *m* and *n*. The specimen is held against the lapping plate by the pressure of the weights, shown in the figure, transmitted to the specimen through the yoke *c*, screw *s* and pin *j*. These parts are supported by a tube *a* held by the split block *b* which in turn is clamped to the connecting rod *f*.

The nut *d*, through which passes the screw *s*, is of tool steel, hardened, ground and lapped to a smooth working fit

the knurled nut *n* is loosened, thus permitting the arm *l* to be turned about the stud *m*.

The lapping plate is shown in section in Fig. 4. The lap surface is at *A*. A gray iron plate, cast originally $\frac{1}{2}$ in. thick and finished down to $\frac{3}{4}$ in. thick, is held to the lower plate *B* by means of screws. The outer rim *C* is also fastened by screws and is removable.

The copper and steel laps were built up the same way. The copper plate was made of plate copper $\frac{1}{4}$ in. thick; since this was too thin to be tapped into, it was secured to the cast plate by means of solder. The steel plate was made of fire-box steel $\frac{1}{4}$ in. thick and secured in the same manner as the copper plate. The surfaces of all laps were finished by grinding.

The distributor, or wiper, is an important feature of the machine. It is shown in detail in Fig. 5. It was essential that there be a uniform distribution of the charge of abrasive over the entire surface of the plate. Centrifugal force was depended upon to work the charge from the center of

the plate outward, and a wiper, *T*, consisting of a strip of wood resting on the plate and inclined at an angle of 15 deg. to a radial line from the center, was counted on to shear the charge back toward the center. Motion was given to the wiper through the medium of an eccentric *R* placed on the shaft *D*. To prevent an accumulation of part of the charge around the inner surface of the outer ring, a small auxiliary wiper was placed as shown at *Q*.

The test specimens were of hardened tool steel, of $\frac{5}{8}$ -in. drill rod. Fifty-five pieces $\frac{1}{2}$ in. long were cut from the same bar and numbered consecutively. They were hardened by heating in the muffle of a regulated gas furnace, and quenching in clear salt water.

Three abrasives were selected as being representative of those on the market. These were Naxos Emery, from the Safety Emery Wheel Co., Springfield, O.; Carborundum, di-

FIG. 2 OUTLINE TRACED BY SPECIMEN ON LAP

rect from the Carborundum Company, Niagara Falls, N. Y., and Alundum, from the Norton Company, Worcester, Mass. All the tests were carried out with abrasive No. 150. Each of the abrasives was tried with seven different lubricants, five different pressures, and three different laps. The lubricants were lard oil, machine oil, kerosene, gasoline, turpentine, alcohol, and soda water.

Starting a series of tests, say with emery as the abrasive and with east iron lap, the first test was made with lard oil and with a pressure of 5 lb. per sq. in. on the specimen. The pressure was then increased to 19 lb. per sq. in., other conditions remaining the same, and another run made. The pressures were then increased to 15, 20, and 25 lb., giving a group of five runs with lard oil.

Machine oil was then substituted for lard oil and a like group of tests made, after which tests were made with the other lubricants in the same way. This gave for east iron-emery a series of 35 tests.

Carborundum was next substituted for emery and the same number of tests repeated. This was followed by a like series with alundum, making the total number of tests with east iron lap 105.

The east iron lap was then replaced by one of steel and a second series of 105 tests run with the steel lap. This was followed by a like series with the copper lap.

The conditions of the tests are described fully in the paper.

The log of a single test is shown in Fig. 6, while Fig. 7 shows the plotted results of a typical individual test of the east iron-emery series. A summary of all the results of tests is given in Table 1.

In Fig. 8 is given a typical series of characteristic curves obtained by summing up the ordinates of the individual test curves for the different lubricants, abrasives and lap materials. For instance, the gasoline curve in this figure is obtained by summing up all the ordinates of the five curves in Fig. 7.

Lubricants. The action of the different lubricants presents an interesting study. The same lubricant acts differently with the different abrasives and again differently with different laps.

Taking the results of the emery-cast iron series of tests alone, as shown in Fig. 8, it would seem that the change in the viscosity and lubricating properties would offer a reasonable and fairly complete explanation of the difference in their behavior. Gasoline, which is lowest in these respects, has the highest rate of cutting, which is well maintained, being nearly as high at the end of 4000 rev. as at the beginning. Next is kerosene, the rate of cutting of which is high, but which shows slightly more of a decreasing rate as the end of the run is approached. Soda water is below kerosene, but maintains its rate of cutting more like gasoline.

The paper here includes a detailed consideration of the results from various lubricants. The following is a summary:

Lard and Machine Oil. For these lubricants, it is to be observed:

- That in tests under all conditions, their curves are of the same form and follow each other closely.
- That lard oil without exception gives the higher rate of cutting.
- That in general the initial rate of cutting is higher than with the lighter lubricants, but falls off more rapidly as the run proceeds.
- That both the highest and lowest results of the whole number of tests were obtained with these two lubricants. The lowest with machine oil, emery-cast iron lap, with lard oil a little above it; the highest with lard oil, carborundum-steel lap, with machine oil a little below it.

Table 2 shows this progressive increase in the values obtained with the different combinations:

TABLE 2 AMOUNT GROUND FROM SPECIMEN WITH MACHINE OIL AND LARD OIL FOR THE DIFFERENT COMBINATIONS OF LAP AND ABRASIVE

MACHINE OIL			LARD OIL		
Cast Lap	Emery	1320	Cast Lap	Emery	1673

	Carborundum	2825		Carborundum	3340
Steel Lap	Emery	1744	Steel Lap	Emery	2160
	Alundum	1890		Alundum	2557
	Carborundum	4199		Carborundum	4619
Copper Lap	Emery	3250	Copper Lap	Emery	3459
	Alundum	3997		Alundum	4065
	Carborundum	4148		Carborundum	4540

Gasoline and Kerosene. On the cast iron lap gasoline shows the highest results of any of the lubricants tested. It is not so good on copper and still less so on steel. Taking into account all three abrasives, its relative value on the different laps is as follows:

Cast iron 127 Copper 115 Steel 106

Kerosene shows more nearly the characteristics of gasoline than of the heavier oils. Like gasoline, it gives the best results on cast iron and the poorest on steel. It does not work so well with carborundum on the copper lap.

Turpentine and Alcohol. There is no evidence to show that turpentine possesses any superior advantage over the other lubricants. On any lap it does good work with carborundum. With emery it does fair work on the copper lap, but with emery on the cast iron and steel lap it is distinctly inferior.

Alcohol in some ways acts very much like turpentine. It also gives the lowest results with emery on the cast iron and steel laps.

Soda Water. Soda water gives reasonably good results with almost any combination of lap and abrasive. While it is seldom the best, it is never the worst. It does its best work on the copper lap and poorest on steel, although there is not much difference between its work on the cast iron and steel. On the cast iron lap it does better work than machine oil or lard oil, but not so good as gasoline.

Abrasives. It may be well to call attention to the fact that emery and alundum are similar abrasives, both being aluminum oxides of the form Al_2O_3 . Emery is a natural product, more or less contaminated with iron or other impurities. Alundum is an artificial product and, in general, of greater purity than the natural product. Carborundum, on the other hand, is an entirely different material, being a carbide of silicon, SiC . Naturally, then, emery and alundum might be expected to show more nearly the same characteristics, while carborundum would deviate more or less from them.

The curves in Figs. 9 and 10 show the rates of cutting for the three abrasives with cast iron lap, and with machine oil and lard oil respectively. The paper gives similar sets of curves for all the different combinations of lap and lubricant.

The total amounts of steel ground from the specimens with each abrasive are given in Table 3.

TABLE 3 AMOUNTS IN MILLIGRAMS GROUND FROM SPECIMENS WITH DIFFERENT COMBINATION OF LAP AND ABRASIVE

(Emery 18105		(Emery 17965		(Emery 25612	
Cast Lap	Alun. 21733	Steel Lap	Alun. 21712	Copper Lap	Alun. 28499
	Carb. 27673		Carb. 28188		Carb. 28646

The evidence all the way through tends to the conclusion that there is for each different combination of lap and lubricant a definite size grain of abrasive that will give maximum rate of cutting.

The hardness of the various laps, as determined by the research department of the Westinghouse Electric and Manufacturing Co., was as follows:

By the brinell method			
Cast iron 109	Steel 87	Copper 43	6
By the scleroscope			
Cast iron 28	Steel 18	Copper 5	

A comparison of the three laps with all combinations of abrasive and lubricant is given in twenty sets of curves. Two sets are shown in Figs. 11 and 12.

Figures are given to show that, with the proper abrasive

FIG. 3 SECTION THROUGH SPECIMEN HOLDER

and lubricant, steel and cast iron are equally as good (for all practical purposes) as copper.

Wear of Laps. One of the remarkable facts brought out was the great difference in wear of the laps. The wear on all laps was about twice as fast with carborundum as with emery, while with alundum the wear was about one and one-fourth times that with emery. On an average the wear of the copper lap was about three times that of the cast lap. Table 4 shows this clearly.

TABLE 4 AMOUNTS GROUND FROM THE LAP SURFACE FOR EACH 100 MILLIGRAMS GROUND FROM THE SPECIMEN

EMERY		ALUNDUM	CARBORUNDUM	TOTAL
Cast iron	81.2	118	158	357.2
Steel	114	149	190	453
Copper	233	293	410	938

As regards permanence of form, cast iron is altogether better than either steel or copper, and taking into account its first cost and that with proper abrasive and lubricant its rate of cutting is practically as good as copper or steel, it is far and away the best lap material.

From results obtained on the wear of the laps, it is evident that the theory of the lodgment of the abrasive in the softer lap surface is not well founded. The action appears to be more mutual between the surfaces.

Within the limits of the pressures used; that is, up to 25

FIG. 4 SECTION THROUGH LAPPING PLATE

FIG. 5 PLAN OF DISTRIBUTOR

lb. per sq. in., the rate of cutting is practically proportional to the pressure.

The higher pressures, 20 and 25 lb. per sq. in., did not do so well on the copper lap as on the others. There was some evidence tending to show that for this lap the practical limits of pressure had been reached.

Of the 63 combinations tried out, the 15 giving best results are presented in Table 5.

Dry Lapping. Experiments on dry lapping were carried out on the cast iron, steel and copper laps and also on one of tin made expressly for the purpose.

Carborundum alone was used as the abrasive and a uniform pressure of 15 lb. per sq. in. was used on the specimen throughout the tests. In dry lapping much depends on the manner of charging the lap.

The results of these tests are shown in curves in the paper

TABLE 5 COMPARATIVE VALUES OF THE BEST COMBINATIONS, TAKING EMERY-CAST IRON LAP AND MACHINE OIL AS UNITY

Carborundum—Steel lap —Lard oil	3.52
Carborundum—Copper lap—Lard oil	3.14
Carborundum—Cast lap —Gasoline	3.12

Carborundum—Steel lap —Machine oil	3.17
Alundum —Copper lap—Turpentine	3.15
Carborundum—Copper lap—Machine oil	3.14
Alundum —Copper lap—Alcohol	3.10
Carborundum—Copper lap—Alcohol	3.09

and are tabulated in Table 6. Fig. 13 gives one set of curves.

The greatest difference due to different charging is shown by the tin lap. When abrasive No. 150 is rolled into its surface the cutting is about two and one-half times as fast as when the same abrasive is rubbed in. Also it is about three times as fast as when abrasive "F" is rolled, and six times as fast as when "F" is rubbed in.

TABLE 6 RESULTS OF TESTS ON DRY LAPPING

Lap	REVOLUTIONS			
	100	200	300	500
	Milligrams ground from specimen			
Cast	3.6	6	7.6	8.6
Carborundum No. 150 lap Steel charged by rolling	10.3	13	15.3	16.6
Copper	11.3	16.3	19	23.3
Tin	18.6	25.6	30.6	39
Cast	2	3.3	4	5
Carborundum No. 150 lap Steel charged by rubbing	6.6	8.6	9.6	11
Copper	6.6	9.6	11.6	13.6
Tin	7.3	10.3	12.3	15.3
Cast	8.6	12.6	14.6	16.6
Carborundum "F" lap charged by rolling	6.3	8.3	9.3	10.6
Copper	6	8	9.6	11
Tin	7	9.3	10.3	12
Cast	2.6	5	6	7
Carborundum "F" lap charged by rubbing	5	7	8	9
Copper	3	5	6.6	8.6
Tin	2	4	5	5.3

It thus appears that with soft and ductile materials like copper and tin the best results are to be obtained by rolling a comparatively coarse abrasive into the surface, but that with a harder and more brittle material like cast iron a finer grade should be used.

A comparison between the wet and dry methods is more or less unsatisfactory. In dry lapping the rate of cutting decreased rapidly after the first 100 revolutions of the machine—much more rapidly than with the wet method. It seems no more than fair, then, in making comparisons to consider the amounts ground off during the first 100 revolutions. Further, the highest result obtained with each lap is taken as the basis of comparison. With these data, it is found that with the tin lap, charged by rolling carborundum No. 150 into the surface, the rate of cutting, dry, approaches that of the wet. With the other laps, the rate for dry is about $\frac{1}{2}$ that of the wet. Table 7 exhibits this.

It may be of interest to know the rate of cutting in linear measure. With the size of specimen used, the removal of 39 milligrams represented a length of 0.001 in. With a pressure of 15 lb. per sq. in., the average of the best results was just about 22 mg. for 100 revolutions of the machine. The length of path traversed by the specimen was 36 in., or 3 feet per revolution. Hence, the specimen moved over the lap a distance of 300 ft. to have ground from its surface 0.00056 in., or 0.00019 in. for 100 ft. of travel over the lap surface.

With dry lapping on the tin lap, the best result was 18.6 mg. for 100 revolutions, which gives 0.00016 in. per 100 ft. of travel. This is with a pressure of 15 lb. per sq. in. on the specimen, and, of course, with a higher pressure a greater amount would be ground off.

FIG. 6 LOG OF A TYPICAL TEST

The main facts, as developed by the investigations and deductions therefrom, are summarized as follows:

- a The initial rate of cutting is not greatly different for the different abrasives.
- b Carborundum maintains its rate better than either of the others, aluminum next, and emery the least.
- c Carborundum wears the lap about twice as fast, and aluminum $1\frac{1}{4}$ times as fast as emery.
- d There is no advantage in using an abrasive coarser than No. 150.
- e The rate of cutting is practically proportional to the pressure.
- f The wear of the laps is in the following proportions:
Cast iron 1.00 Steel 1.27 Copper 2.62
- g This wear is inversely proportional to the hardness by the brinell test.
- h In general, copper and steel cut faster than cast iron, but where permanence of form is a consideration, cast iron is the superior metal.

TABLE 7 COMPARISON OF WET AND DRY LAPPING; PRESSURE, 15 LB.; ABRASIVE, CARBORUNDUM; 100 REV. OF MACHINE

	Best results with			
	Cast Lap	Steel Lap	Copper Lap	Tin Lap
Wet	20	21	22	
Dry	8.6	10.3	11.3	18.6

- i Gasoline and kerosene are the best lubricants to use with cast iron lap; kerosene, on account of its non-evaporative qualities, being first choice.
- j Machine and hard oil are the best lubricants to use with copper or steel lap. They are least effective on the cast lap.
- k For all laps and all abrasives (of those tested), the cutting is faster with lard oil than with machine oil.
- l Alcohol shows no particular merit for the work.
- m Turpentine does fairly good work with carborundum, but in general is not as good as kerosene or gasoline.
- n Soda water compares favorably with other lubricants. Taken as a whole, it is slightly better than alcohol and turpentine.

FIG. 7 CHARACTERISTIC CAST IRON-EMERY TEST

FIG. 8 COMPARISON OF LUBRICANTS

- o Wet lapping is from 1.2 to 6 times as fast as dry lapping, depending on material of the lap and manner of charging.
- In an appendix is given a rather full bibliography of the subject of lap and lapping.

DISCUSSION

CHARLES E. GILLETTE (written). Except for the work of Schlesinger at Charlottenburg, in 1906, for the Prussian Department of Commerce and Labor, very little of a purely scientific character covering grinding has been published. Professor Alden in his paper, Operation of Grinding Wheels in Machine Grinding, presented before this Society last De-

ember, sets forth the controlling factors governing the action of abrasives when used in the form of grinding wheels; the principles brought out in his paper will form the basis of much valuable experimental work in the future.

The authors are, therefore, to be complimented for their addition to the small store of available data on the action of abrasives under actual operating conditions.

In lapping, as in other operations requiring the use of abrasives for the removal of material, rule of thumb methods have predominated, and such information as has been obtained cannot be said to have been based upon scientific investigations.

FIGS. 9-10 COMPARISON OF ABRASIVES

FIGS. 11-12 COMPARISON OF LAPS

Lapping, in the sense accepted by our best mechanics, infers the use of a perfect master surface to obtain upon a piece of work a level surface and a certain finish or accuracy of dimensions compatible with the purpose for which the lapped piece is to be used. In tool making, where accurate duplication of parts is necessary, lapping reduces the chance for wear and insures the maintenance of standards. In opti-

cal work lapping is resorted to for the purpose of obtaining as near as possible absolutely accurate dimensions, together with a finish or polish that will not interfere with the passage of light waves.

For roughing or blocking down, that is, where the work has not been ground on a surface grinding machine previous to the lapping operation, a different method is used. It would seem, therefore, that while the authors have conducted tests along the methods used in blocking down, the information obtained regarding the action of the abrasives could not be successfully utilized in actual lapping practice.

The point which is most forcibly brought out is that car-

FIG. 13 TYPICAL CURVES OF DRY LAPPING TESTS

bide of silicon acts more efficiently on hardened steel than do the aluminous abrasives. One of the absolute laws of grinding is that aluminous abrasives act more efficiently on materials of high tensile strength, like steel and its alloys, while the carbide of silicon is most efficient on materials of a low tensile strength, such as cast iron, brass, bronze, etc. This is due to the physical properties of the two abrasives, the one being very hard and tough while the other is slightly harder, but relatively quite brittle.

However, lapping may bring into action different properties of the abrasives than is obtained in the solid abrasive wheel. In lapping, the grains are under compression, while in a grinding wheel each grain on the grinding surface might be considered a cantilever subjected to sudden loading at its end, repeated with great frequency.

Considering that the action of an oilstone is like that of a lap which has been charged by either having the abrasive rubbed or rolled into it, the results of a series of tests conducted by the Norton Company may be of interest. The object of these experiments was to compare the cutting qualities of oilstones made of aluminous and carbide of silicon abrasives. The only variable was the composition of the oilstones—there being one aluminous and three carbide of silicon abrasives used. The lubricant was a light grade of machine oil.

A universal grinding machine was used in the test, a special attachment being devised to hold the test piece—a hardened steel chisel with a 1½ in. blade. The oilstone was

clamped to the table of the machine and traversed under the chisel blade at a fixed velocity. The chisel was so prepared that the surface in contact with the oilstone measured $1\frac{1}{2}$ by 1 in.

A pressure of 40 lb. per sq. in. was selected as giving sufficiently accurate results. It was found necessary to use an excessive amount of lubricant to prevent the oilstone from loading or filling up before the end of the test. The chisel blade was traversed a distance of 500 ft. across the oilstone, the stone then being turned over and a run of 500 ft. being made on the other side of the same stone.

While the testing apparatus was not as nicely adjusted as the machine described in the paper, the results obtained were considered sufficiently accurate for commercial purposes. A summary of them follows: Milligrams removed from chisel per 1000 ft. travel across the oilstones

Aluminum	145
Carbide of Silicon No. 1.....	33
Carbide of Silicon No. 2.....	42
Carbide of Silicon No. 3.....	90

These results indicate, without question, that the aluminous abrasive cuts the hardened steel tool much faster than carbide of silicon when used in the form of an oilstone. The size of abrasive used on the oilstones corresponds very closely to the sizes used by Professor Knight in his test.

A very interesting question has been brought out by these tests which ought to be given further consideration. Is there a certain "critical point," so-called, at which all abrasives have an equivalent cutting action under identical test conditions, and either side of which each type of abrasive has its own distinctive field? In other words is carbide of silicon in the coarse sizes more efficient on materials of a low tensile strength and in the fine sizes more efficient on materials of a high tensile strength than aluminous abrasives? A theoretical consideration of the physical properties of the two types of abrasives will show why the action of loose abrasive grains as used in rough lapping may be considerably different than when they are held more or less solidly in a body, such as a charged lap, oilstone or grinding wheel.

The U. S. Bureau of Standards places the hardness of carborundum at 9.6, aluminum 9.4 and emery at approximately 9 on Mohr's scale. Carborundum, a carbide of silicon abrasive, is brittle. Aluminum and emery, aluminous abrasives, are very tough in comparison. Tests upon grains of emery, aluminum and carborundum show the relative compressive strength to be approximately as 1.00: 1.8: 2.0. This shows that emery would break down under straight compression first, aluminum second and carborundum last.

Professor Knight states "emery appears to be more brittle and passes through the change quicker than the others, with aluminum next and carborundum the least susceptible to such a change." Thus it would seem that in blocking down, where the abrasive grains are compressed between the lap and work, the ability to resist crushing is a more important factor than the actual hardness or toughness. Emery, being relatively weaker in compression, breaks down into the impalpable sizes faster than the other abrasives, hence does less effective work during the period of test. This presupposes that the coarser sizes of abrasives cut the faster.

With the abrasive held in a ceramic body, such as an oilstone or grinding wheel, the tougher aluminous grains stand

up under the shearing action of the test piece longer than the brittle carbide of silicon abrasives. The tougher abrasive grains maintain their cutting edges and remain sharp longer than the brittle abrasives, which soon dull over, become glazed and stop cutting.

An examination of the curves in the paper shows that there is no great variation in the initial rate of cutting of any of the abrasives when tried under similar conditions. Any such slight variation might well be caused by a microscopic change in test conditions. Even with the utmost care it is almost impossible to obtain identical conditions in such a test. The wide variation in results obtained in wet and dry lapping or from charging the laps by rubbing or rolling shows the wide limit of the possible results that might be obtained. In testing solid abrasive wheels, the same wide variations are experienced with wet and dry grinding, slight variations in pressure, method of preparing the grinding surface (dressing the wheel) for test, the feeds and speeds used.

It is possible that the slight differences in the sizes of the abrasive grains obtained from the various manufacturers would have an influence on the results as the size of the holes in screens of a certain mesh varies according to the size of the wires used in the screen.

For lapping, a round solid grain which will stand up and maintain its shape is to be preferred to one which will break down and present new sharp cutting points to the work. Such a grain would cut the work being lapped, and in cutting would produce scratches which would be difficult to eliminate.

Commercially only the abrasive flours, so-called, are employed for lapping, in general the size known as FF being the coarsest used. The diameter of a grain of FF averages 0.002 inches and the material is too fine to screen in the usual way. In order to obtain a uniform product, it is necessary to hydraulically classify the abrasive flours.

One of the largest small tool manufacturers in this country having experimented with all abrasives available for lapping found 65F aluminum to be the fastest cutting abrasive material for his purpose. Cast iron laps are used with lard oil as a lubricant. The carbide of silicon flours were found to cut very fast, but at the same time it was impossible to eliminate scratches so deep that they could not be removed under commercial conditions. The amount of wear on the lap increased noticeably at the same time by the use of the carbide of silicon abrasive.

It would seem that, if carbide of silicon grain is more efficient than the aluminous abrasives in lapping hardened steel, then it would be more universally employed in place of the emery and aluminum flours which seem to hold the field at present. It may be that the action of loose abrasive grain is materially different than when held in a body; however the cases are few, in actual practice, where carbide of silicon is more efficient than aluminum when working on materials of a high tensile strength. With this exception, the authors have shown the action of loose grain abrasives in the fine numbers to be similar to the coarser sizes when used in solid wheel form.

The amount of time and patience necessary to obtain data for this paper can only be appreciated by those who have been engaged along similar lines. Professor Knight and Mr. Case are to be commended for the care and detail shown in their paper.

THE SURFACE CONDENSER

BY C. F. BRAUN, SAN FRANCISCO

Associate-Member

THIS paper analyzes the functions of the surface condenser, presents briefly the fundamental principles governing design, discusses rational ratings, and compares typical commercial designs.

The primary functions of a surface condenser are to reduce the back pressure on the exhaust side of a steam prime mover; to conserve and return to the steam generator, in the water of condensation, as many heat units as possible; and to remove air from the feed water, thus reducing pitting of boilers. In accomplishing these results the condenser must handle four separate fluids: steam, air (including other non-condensable vapors), water of condensation, and cooling or circulating water. As the desirable state of these several fluids is not the same, the problem at once becomes a complicated one. Briefly, the conditions to be approached are:

Steam should enter the condenser, be conducted freely to all parts with least possible resistance, reduced to the lowest practicable temperature (and consequently pressure) and converted into water.

Air, a non-conductor, should be rapidly cleared from the heat-transmitting surfaces, collected at suitable places, practically freed from entrained water and water vapor, and cooled to a low temperature for removal at minimum volume, with consequent least expenditure of mechanical energy.

Condensate should also be rapidly cleared from the heat transmitting surfaces, freed from air, collected at suitable points for removal, and returned to the steam generator at the maximum practical temperature.

Circulating water should pass through the condenser with least friction, deposit a minimum amount of precipitated chemicals or debris, and absorb a maximum amount of heat.

The main principle of design of the condenser is the transference of heat from the steam through the dividing surface to the cooling water. The transfer per unit of area or of size is a measure of the efficiency of the apparatus and is directly proportional to the temperature difference or head. The temperature of the water increases during its passage through the condenser, and that of the steam decreases; it is therefore necessary to obtain mean values for temperature differences. A simple arithmetic mean is not correct, but the following formula, developed mathematically by Grashof, has repeatedly been proven accurate and is almost universally adopted.

$$M = \frac{D_1 - D_2}{\log_e \frac{D_1}{D_2}} \dots \dots \dots [1]$$

where

M = mean temperature difference

D_1 = temperature difference between fluids at beginning
= $T S_1 - T W_1$

D_2 = temperature difference between fluids at end
= $T S_2 - T W_2$

$T S_1$ = initial temperature of steam

$T S_2$ = final temperature of steam

$T W_1$ = initial temperature of circulating water

$T W_2$ = final temperature of circulating water

It is commonly assumed that $T S$ is constant throughout the condenser, by which this formula reduces to

$$M = \frac{T W_2 - T W_1}{\log_e \frac{T S - T W_1}{T S - T W_2}} \dots \dots \dots [2]$$

Since the frictional drop through the steam space of a condenser is usually 0.5 in. or more, representing with high vacuums a temperature difference of say 10 deg. fahr., it is evident that the use of formula [2] for applying to large condensers data obtained on smaller ones, or for analyzing the performance of a condenser or various sections of a condenser, will lead to serious errors.

With any given set of temperature values the mean temperature difference can be varied in only one way, namely, by arrangement of heating surfaces. These must be such as to produce counter-current flow, the circulating water entering where the steam is coolest and leaving where it is hottest.

Transfer of heat through a unit of condenser tube area per unit of mean temperature difference was early recognized as varying greatly under different conditions, the most apparent variation being an increase with increase of water velocity. Many experimenters have carried out extensive and careful tests to determine values of this heat transfer and a common formula is $H = K V^{1.2}$. That such a formula is fundamentally incorrect and misleading is at once apparent when it is considered that certain resistances to heat flow, namely, that of the tube and that on the steam side of the tube, are practically constant and entirely independent of the water velocity.

Resistance. The transfer of heat produced by the temperature head is opposed by a total resistance R which for analysis divides conveniently into the resistance R_v on the vapor or steam side of the surface, the resistance R_m of the metal walls of the surface, and the resistance R_w on the cooling water side of the surface. A simple equation expressing heat transfer in useful terms may be written as follows:

$$R = \frac{M}{H}$$

in which

H = number of heat units transferred per unit time

M = mean temperature difference

R = total resistance = $R_v + R_m + R_w$

Even with high steam pressures and with superheat, the total B.t.u. to be extracted by the condenser may safely be assumed as 1000, and it is convenient to adopt an arbitrary resistance unit such that

$$H = \frac{1000 \times M}{R} \text{ or } W = \frac{M}{R} \dots \dots \dots [3]$$

in which

H = B.t.u. per sq. ft. per hour

M = mean temperature difference in deg. fahr.

R = resistance per sq. ft. of surface

W = pounds steam condensed per sq. ft. per hour.

The symbol U will be used when M is unity, so that U = B.t.u. per sq. ft. per hour per deg. mean temperature difference. This resistance R may also be expressed in terms of equivalent conductivity by the equation

$$R = \frac{1000 \times L}{C \times 4290}$$

in which

L = thickness of substance in inches

C = conductivity in e.g.s. units.

The paper here considers the deduction of the resistances R_m , R_v and R_w and how they are influenced by design and by factors of operation, such as coatings of oil, air and scale, upon the condenser surfaces.

FIG. 1 HEAT TRANSMISSION—VELOCITY CURVES

The writer believes that the results of the tests by Orrok¹ (Fig. 1, Curve A) provide the most reliable data available on heat transfer through condenser tubes. In Fig. 2 (curve A) are plotted total resistances R obtained by applying the values from Orrok's curve in Fig. 1 to equation [3], in which M is taken as unity. For convenience, these resistances are plotted against reciprocal velocity instead of against velocity.

The paper shows that for ideal conditions $R_v = 0.333$ and that for a No. 18 gage brass tube $R_m = 0.044$, making $R_v + R_m = 0.333 + 0.044 = 0.377$, and it is reasonable to assume that Orrok's tests approach these conditions sufficiently closely so that a reasonable value to accept for $R_v + R_m$ for his tests is 0.4. On this assumption curve B, Fig. 2, is plotted showing the relation of R_w to the reciprocal velocity.

A curve, Fig. 1 (B), plotted from the values on curve (B), Fig. 2, represents the relation of heat transfer from the surface of a condenser tube to velocity of the water in contact with that surface. From this curve U_w varies directly with V according to the equation

$$U_w = 245 + 141 V.$$

This variation of resistance, inversely with velocity, is due to the fact that the particles of water in contact with the surface at any instant form a non-conductor which prevents the flow of heat from particles in the body of the water to the surface of the tube. The transfer of heat is really by convection, and the more rapid the removal of the heated

particles and their replacement by cooler ones, the greater the heat transfer. With the same velocity this transfer of particles is much more rapid in a small tube than a large one, where, so to speak, a cold core of water exists. This indicates the desirability of small tubes and experience dictates $\frac{3}{4}$ in. to $\frac{7}{8}$ in. inside diameter as a maximum.

For apparent reasons of economical construction most condensers consist of a cylindrical shell containing closely-spaced round tubes. The water may pass through the tubes and the steam around them, or vice versa. While the steam circulates automatically as a result of condensation, the water moves only sluggishly due to slight change of gravity with change of temperature. The arrangement, therefore, of passing the water through the tubes, is invariably employed, thus making it possible to give the water a rapid positive movement.

Among metals commercially available for use in condenser tubes, copper has the highest conductivity and when properly alloyed, is less subject to corrosion than most others, thus permitting the use of thinner surfaces. Hence practically all condenser tubes are copper or high percentage copper alloy.

The size of tube is a determining factor in the thickness, larger tubes requiring greater thickness for mechanical strength, and from this viewpoint also small tubes are desirable.

The arrangement of heating surfaces for easy cleaning and the construction of water channel covers independent of pipe connections is important, although frequently neglected.

To prevent the formation of a coating of oil which has an effect more serious than a coating of scale, a fairly high steam velocity must be maintained over the tubes, and corners which become stagnant places must be eliminated.

FIG. 2 RESISTANCE—RECIPROCAL VELOCITY CURVES

The paper here considers typical designs of condensers, pointing out their advantages and defects.

An exhaust opening of liberal size with a dome extending the length of the shell, Figs. 11 and 14, will cause the steam to be distributed to the ends of the tubes and prevent stagnant corners such as represented by the shaded portions in Figs. 3, 4 and 5.

Baffle plates for directing the steam to remote parts of the condenser introduce resistance to steam flow and should be avoided, except for the small plate directly in front of the exhaust inlet to protect the tubes from entrained water in the exhaust.

¹ Transmission of Heat in Surface Condensation, Geo. A. Orrok, Trans. Am. Soc. M. E., Vol. 32, page 1139.

The steam passing over the tubes condenses and diminishes in volume as it progresses, and hence in ordinary condensers the steam flow velocity rapidly decreases and becomes practically nil in the portion away from the inlet, permitting air to stagnate. This steam flow velocity may be maintained by constructing a gradually reducing steamway, a triangle with steam entering over one entire side, Fig. 6, being theoretically

Fig. 10 shows a commercial form of condenser which, however, has a shell of a shape that is somewhat inconvenient to construct. Fig. 9 shows similar taper passages embodied in a round shell, but the large heavy baffle plates which occupy the available tube space are objectionable. Fig. 7 shows this feature also, but the shape of the shell and the resistance to steam flow make it an impractical construc-

correct, or by gradually reducing the pitch of the tubes or by making lanes or passages to various parts of the steam space by omitting tubes, Figs. 11 and 14. Any one of these methods properly applied should be effective and result in good steam distribution at uniform velocities, prevent the stagnation of air at any point, and minimize the frictional drop.

The design in Fig. 8 likewise has too many baffles which increase the weight and obstruct the steam flow. The design in Fig. 14 approaches that of the others in principle, but the shape of the water passages is objectionable; when a condenser is incorporated in the base of a turbine, these lanes should start from opposite the buckets as nearly as possible.

If a liberal pitch be employed for the tubes, and ample lanes be provided, the frictional drop, even through a large condenser, need not exceed 0.4 in. and less in smaller ones. Figs. 11, 13 and 14 show proper distribution, but Figs. 4, 7, 8, and 12, having long steamways and closely pitched tubes, may have frictional drops as great as 2 in.

It is important that a sufficient number of air removal connections be located at points where air accumulates (Fig. 11).

The quantity of air allowed to enter a condenser should at all times be minimized and the importance of tight joints and pipe connections should be impressed upon operators. As only a very small quantity can enter with the feed water, it is evident that proper operating attention to the tightness of condenser shell, low-pressure stages of the turbine, piping and valves, will reduce the air in the condenser to a very low figure. If a large quantity of air were present in a condenser, it could be detected by vacuum and temperature readings taken at the same part of the steam space, the tem-

perature indicated being that of the vapor, and the pressure that of the sum of the pressures of the vapor and of the air.

rapid increase of frictional resistance and consequent cost of pumping, erosion of the tubes if the water contained sand, and an undesirable number of passes or a very long condenser. For these reasons a velocity flow is ordinarily limited to about 4 to 6 ft. per second. Experience shows 1 in. outside diameter to be the lower limiting size of tubes and this allowable only in very large condensers having a high circulating water ratio. Frictional loss may be minimized by using long tubes and fewer passes, reducing water passage and tube entrance loss.

Even distribution of water through all tubes is important and narrow channels causing high velocities, Figs. 3 and 4, or inlets directing water onto the tubes, Fig. 3, must be avoided, since uneven distribution is sure to result, those tubes not in the stream line receiving little water and being therefore largely ineffective.

Curve *C*, Fig. 1, is arrived at by accepting a coefficient of heat transmission *U*, of say 550, for a water velocity of 4 ft. per sec. This coefficient is about the best obtainable in prac-

FIG. 11 WELL-DESIGNED CYLINDRICAL CONDENSER

perature indicated being that of the vapor, and the pressure that of the sum of the pressures of the vapor and of the air.

In order to determine the completeness of the distribution of the steam to all parts of the steam space, the writer has computed the coefficient of heat transmission *U* for each pass for two large condensers and has found this coefficient for the first pass only about 10 per cent. less than for the second, indicating that with proper steam distribution and effective air removal the value of *U* will be about the same for all parts of the surface. If, however, steam distribution is poor and the clearing away from the surfaces and the removal of the air unsatisfactory, the value of *U* for the first pass may be only 50 per cent. of that in the second. In a like manner, if the tubes away from the center are not doing their proportion of work, this will be indicated by the temperature readings taken on the water flowing from them.

The resistance on the water side of the condenser could be eliminated if very high water velocities through exceedingly small tubes could be used. This, however, would cause a

notice and there are considerable data available for this water velocity. By comparing this with the valve on curve *B*, Fig. 1, the value of $R_s + R_m$ is determined as say 0.6, which is used in plotting the points on curve *C*, Fig. 2. Perhaps in most cases a value of 0.8 for $R_s + R_m$, giving curve *D*, would be safer to use for design. If we accept 4 as a desirable water velocity we obtain from curve *D*, Fig. 2, $R = 2$, corresponding to an allowable value for *U* of say 500 B.t.u.

There follows in the paper a consideration of condenser design with reference to desirable temperature conditions and methods of removal from the condenser for each of the four fluids.

Steam must be maintained at the lowest practicable pressure, and hence the temperature must approach closely that of the circulating water discharge. There must be a difference, however, in order to produce heat flow; this should be kept within 10 deg. Fahr.

Air must be removed from the condenser by a mechanical pump, the energy required for operation being directly proportional to the volume of air moved. This volume

should be minimized by causing the air finally to pass over the coldest tubes.

The curves, Fig. 15, show the enormous effect, upon the volume of air mixed with saturated water vapor, of the partial pressure of the steam as indicated by the temperature. Thus, with a vacuum of 28 in. (2 in. absolute) corresponding to a steam temperature of 101 deg. Fahr., 1 lb. of air, for a temperature of the mixture of 95 deg. Fahr. corresponding to a partial steam pressure of 1.6 in. will have a volume of say 1200 cu. ft.; whereas if the partial pressure of the steam is reduced to 1 in. absolute, bringing the temperature of the mixture to 80 deg. Fahr., this volume will be only 400 cu. ft. These figures indicate the importance of embodying in the condenser design an air cooler, especially in condensers with high vacuum.

Actual tests have proven that for ordinary wet vacuum pumps to handle the mixture of air, vapor, and water and maintain even moderately high vacuums it is necessary to cool the condensate 10 to 15 deg. below that due to the vacuum, which of course requires more circulating water and wastes more heat from the system. Another serious objection to the wet vacuum system is that compressing an emulsion of air and water is a most effective method of mixing the air with the condensate to return to boilers. Centrifugal air pumps having no clearance space, do not lose efficiency at high vacuums, and are rapidly coming into use, but the reciprocating type still has the advantage of requiring much less power for operation.

Condensate should be removed at a high temperature. Especially in large condensers, a number of condensate removal connections should be provided on the shell to insure free and quick flow to the removal pump, generally a centrifugal which, unlike a plunger pump, will handle varying quantities without speed changes, and which if properly vented never becomes vapor-bound.

Circulating water, to reach minimum quantity, must have an exit temperature closely approaching the steam temperature. The great effect of a comparatively small variation in this temperature may be appreciated by considering the maintenance of a 29 in. vacuum (79 deg. Fahr.) with circulating water at 60 deg. Fahr., the quantity required being twice as much if heated to within 14 deg. of the steam temperature, than if heated to within 9 deg., and the energy required to pump the circulating water being 8 times as much.

The optimum amount for this minimum temperature difference is always a compromise between condenser cost and pump and pumping cost, but with well designed apparatus should not exceed 10 deg. Fahr. With poor designs, especially those having parallel flow, this difference is sure to be 15 to 20 deg. Fahr. For service with circulating water obtained from cooling towers or other expensive source it might be warrantable to have this difference as low as 5 deg. Fahr.

Regarding general structural features, proper provision for accommodation of expansion strains is usually accomplished by securing tubes into the tube sheets with packings and ferrules; a more modern method is to expand the tube into one head and pack at one end only, thus eliminating one half the leak possibilities. The proper supporting of tubes to prevent sagging and cracking is important and supporting plates drilled true with the tube sheet should be located not more than 8 ft. apart. Shells should be made of cast iron, and not of steel, which is corroded by the gases con-

tained in the steam, and water channels and covers should be separate castings so that tube ends may be readily exposed for cleaning without breaking pipe connections.

The connections between and relative location of condensers and auxiliaries are important factors in condenser efficiency, but in most cases are beyond the control of the manufacturer and consequently are neglected and are a common source of condenser trouble. The exhaust pipe, condensate piping and air pump piping should all be amply large, although the last is ordinarily much larger than necessary.

The surface condenser, like most other apparatus, is subject to irrational, meaningless, and misleading ratings, the most objectionable being square feet per engine horse power, on account of the wide variation in the amount of steam required per engine horse power, say 9 to 25 lb. per hour. The more common rating is pounds steam condensed per

FIG. 12 BASE AND DOUBLE WING CONDENSER, ILLUSTRATING EXCESSIVELY LONG STEAMWAY

FIG. 13 BASE CONDENSER WITH TAPER PASSAGE

FIG. 14 CONDENSER GIVING TAPER PASSAGE EFFECT WITHOUT BAFFLES

square foot, common marine practice being to allow 1 sq. ft. per 10 lb. of steam and to hope for a vacuum somewhere between 23 in. and 26 in.; this is little better as it does not consider even cooling water temperature which may range from say 40 to 80 deg. Fahr. A comprehensive rating must include the following:

- (a) Quantity of steam condensed.
- (b) Vacuum obtainable (corrected to 30 in. barometer).
- (c) Temperature of available cooling water.
- (d) Cooling water exit temperature.
- (e) Condition of air at point of removal.
- (f) Friction head on cooling water.
- (g) Temperature of condensate at point of removal.

The first four items express the heat transmitting efficiency

and can for purposes of comparison be reduced to B.t.u per sq. ft. per deg. difference per hour.

Since a higher vacuum at the air pump than at the exhaust inlet is of no value, the mean temperature difference used for comparing results on condensers should be computed, on the assumption that the steam temperature

The complete equation for the condenser is

$$S = \frac{W \times Q}{M \times U} \text{ or } U = \frac{W \times Q}{M \times S}$$

in which

U = B.t.u. per sq. ft. per deg. fahr. difference per hour.

$=$ coefficient of heat transmission.

M = Mean temperature difference in deg. fahr.

W = Pounds steam condensed per hour.

S = Square feet of cooling surface.

Q = Total heat removed by circulating water per pound steam condensed (usually taken as 1000 in all cases for simplicity).

Thus for example, assuming results as follows from two condensers, we can say that A is 50 per cent. more efficient than B.

DISCUSSION

P. E. REYNOLDS (written). A few years back it appeared to be the main idea of the designer to crowd as much cooling surface as possible into the least space, regardless of accessibility of the surface to the steam, or the friction loss entailed in bringing the steam to the surface.

There is no doubt that large exhaust openings, combined with steam distributing domes of ample dimensions and steam lanes or passages through the tubes, are some of the main features of efficient surface condensers designed to maintain high vacua.

Regarding the variations of heat transfer with water velocity, although Mr. Braun may be theoretically correct in stating that Mr. Orrok's exponential formula is fundamentally wrong, since the resistance to heat transfer of the tube itself and that on the steam side of the tube are constant, yet it seems that since these resistances are constant it is a useless complication for all practical conditions of condenser designs to take them into consideration.

Regarding parallel flow and counter-current condensers, I agree with Mr. Braun that the latter give the best results; however, Mr. Braun's proof of the fact by means of the general formula

$$M = \frac{T_1 - T_2}{\log_e \frac{T_1}{T_2}}$$

for the logarithmic mean temperature difference I do not consider correct. It is my understanding that in the mathematics involved in the derivation of this formula, the assumption is made that the heat absorbed by the cooler fluid results in a corresponding decrease in temperature of the hotter fluid. As these conditions do not prevail in a steam condenser, since the steam temperature is not decreased by the abstraction of heat at constant pressure, I would not consider that this formula could be correctly applied.

The formula:

$$M = \frac{TW_1 - TW_2}{\log_e \frac{TS - TW_1}{TS - TW_2}}$$

based on the assumption that the steam temperature TS is constant throughout the condenser, is the only one that can be correctly used. However, it appears that too much weight should not be attached to the mean temperature as given by this formula, since the assumptions on which its mathematics is based are not fulfilled in actual surface condensers, and if a true mean temperature difference between the cooling water and steam is desired, it is probable that the arithmetical mean is as nearly correct as any.

H. WADE HIBBARD mentioned that in the author's reference to the exhaust pipe between the engine and condenser

he would suggest adding that in some installations it is desirable to use a steam separator to remove the water from the exhaust steam before it goes to the condenser.

THE AUTHOR. Referring to the remarks of Professor Hibbard, who suggests that it may be desirable to have a steam separator between the prime mover and the condenser, I will assume that he thinks it advisable to remove the water from the exhaust steam so as to reduce the coating of condensate which will adhere to the condenser tubes. This has been tried many times, and very elaborately by one or two manufacturers, that is, by the installing of drain plates, which might be called separators, in the condenser; and it has been invariably found that these will offer resistance to the flow of steam, besides complicating and increasing the cost of the design, which more than offset any possible value that they might have in increasing the heat transfer by reason of decreasing the resistance on the steam side of the tube, and I feel sure that this is now an established fact.

Replying to Mr. Reynolds' remarks, I must point out some obvious fallacies.

His statement that the resistance R_s on the steam side of the tube, and the resistance R_m of the tube are, in condensers, nearly constant, does not agree with facts.

Actually, R_s varies greatly with varying amounts of air present, as is plainly apparent when one considers the marked effect upon vacuum produced by even the most minute of air leaks. Furthermore, repeated tests on two-pass condensers, from which the performances of each half the condenser has been computed separately, have invariably shown that the coefficient of heat transfer is less in that half which contains the air outlets.

R_m , which properly includes the resistance of *any solids adhering to the tube*, increases greatly, as we all well know, when the condenser becomes foul with scale or oil, and the value to be given it should depend upon the quality of the circulating water, the presence or absence of oil in the exhaust and the continuity of service required.

Mr. Reynolds' limitation of the logarithmic mean temperature difference formula is also incorrect. The only assumption involved in the mathematical derivation is the proportionality of heat transmitted to the first power of the temperature difference. This proportionality is not absolutely true in a commercial condenser, due to the presence of air, but it is certainly more desirable to start with rational and the theoretically correct formula, making allowances in practical design for known influencing factors, than to revert to rule of thumb methods and accept formulae such as the arithmetical mean for temperature difference which we know to be fundamentally wrong. To fulfill Mr. Reynolds' conditions for the correctness of formula [1] it is only necessary to consider the steam as a fluid having an infinitely large specific heat.

THE RELATION BETWEEN PRODUCTION AND COSTS

BY H. L. GANTT, NEW YORK

Member of the Society

MANUFACTURERS in general recognize the vital importance of a knowledge of the cost of their product, yet but few of them have a cost system on which they are willing to rely under all conditions.

While it is possible to get quite accurately the amount of material and labor used directly in the production of an article, and several systems have been devised which accomplish this result, there does not yet seem to have been devised any system of distributing that portion of the expense known variously as indirect expense, burden or overhead, in such a manner as to make us have any real confidence that it has been done properly.

There are in common use several methods of distributing this expense. One is to distribute the total indirect expense, including interest, taxes, insurance, etc., according to the direct labor. Another is to distribute a portion of this expense according to direct labor, and a portion according to machine hours. Other methods distribute a certain amount of this expense on the material used, etc. Most of these methods contemplate the distribution of *all* of the indirect expense of the manufacturing plant, however much it may be, on the output produced, no matter how small it is.

If the factory is running at its full, or normal, capacity, this item of indirect expense per unit of product is usually small. If the factory is running at only a fraction of its capacity, say one-half, and turning out only one-half of its normal product, there is but little change in the total amount of this indirect expense, all of which must now be distributed over half as much product as previously, each unit of product thereby being obliged to bear approximately twice as much expense as previously.

When times are good, and there is plenty of business, this method of accounting indicates that our costs are low; but when times become bad and business is slack, it indicates high costs due to the increased proportion of burden each unit has to bear. During good times, when there is a demand for all the product we can make, it is usually sold at a high price and the element of cost is not such an important factor. When business is dull, however, we cannot get such a high price for our product, and the question of how low a price we can afford to sell the product at is of vital importance. Our cost systems, as generally operated at present, show under such conditions that our costs are high and, if business

Mr. Gantt's paper at the Spring Meeting drew out a large amount of discussion, which is here reported nearly in full. The paper contends that, whereas it has been common practice to make the products of a factory running at a portion of its capacity bear the whole expense of the factory, the only expense logically chargeable to a product is that needed for its production when the factory is running at its full or normal capacity. The expense of any portion of a plant not needed in production is a business expense to be deducted from profits, or entered as a loss if the profits will not cover it. The determination of the expense required for normal operation is primarily an engineering problem, instead of an accounting problem, and the cost accountant of the future must himself be an engineer.

is very bad, they usually show us a cost far greater than the amount we can get for the goods. In other words, our present systems of cost accounting go to pieces when they are most needed. This being the case, many of us have felt for a long time that there was something radically wrong with the present theories on the subject.

As an illustration, I may cite a case which recently came to my attention. A man found that his cost on a certain article was 30 cents. When he found that he could buy it for 26 cents, he gave orders to stop manufacturing and to buy it, saying he did not understand how his competitor could sell at that price. He seemed to realize that there was a flaw somewhere, but he could not locate it.

I then asked him what his expense consisted of. His reply was labor 10 cents, material 8 cents, and overhead 12 cents. My next question was: Are you running your factory at full capacity? I got the reply that he was running it at less than half its capacity, possibly at one-third. The next question was: What would be the overhead on this article if your factory were running full? The reply was that it would be about 5 cents; hence the cost would be only 23 cents.

The possibility that his competitor was running his factory full suggested itself at once as an explanation.

The next question that suggested itself was how the 12 cents overhead, which was charged to this article, would be paid if the article was bought. The obvious answer was that it would have to be distributed over the product still being made, and would thereby increase its cost. In such a case it would probably be found that some other article was costing more than it could be bought for; and, if the same policy were pursued, the second article should be bought, which would cause the remaining product to bear a still higher expense rate.

If this policy were carried to its logical conclusion, the manufacturer would be buying everything before long, and be obliged to give up manufacturing entirely.

The illustration which I have cited is not an isolated case, but is representative of the problems before a large class of manufacturers, who believe that *all of the expense, however large, must be carried by the output produced, however small.*

This theory of expense distribution is quite widespread, and clearly indicates a policy, which in dull times would, if followed logically, put many of our manufacturers out of business. In 1897 the plant of which I was superintendent was put out of business by just this kind of logic. It never started up again.

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion; price 5 cents to members; 10 cents to non-members.

Fortunately for the country, American people as a whole will finally discard theories which conflict with common sense; and, when their cost figures indicate an absurd conclusion, most of them will repudiate the figures. A cost system, however, which fails us when we need it most, is of but little value and it is imperative for us to devise a theory of costs that will not fail us.

Most of the cost systems in use, and the theories on which they are based, have been devised by accountants for the benefit of financiers, whose aim has been to criticize the factory and to make it responsible for all the shortcomings of the business. In this they have succeeded admirably, largely because the methods used are not so devised as to enable the superintendent to present his side of the case.

Our theory of cost keeping is that one of its prime functions is to enable the superintendent to know whether, or not, he is doing the work he is responsible for as economically as possible, which function is ignored in the majority of the cost systems now in general use. Many accountants, who make an attempt to show it, are so long in getting their figures in shape that they are practically worthless for the purpose intended, the possibility of using them having passed.

In order to get a correct view of the subject we must look at the matter from a different and broader standpoint. The following illustration seems to put the subject in its true light:

Let us suppose that a manufacturer owns three identical plants, of an economical operating size, manufacturing the same article,—one located in Albany, one in Buffalo and one in Chicago,—and that they are all running at their normal capacity and managed equally well. The amount of indirect expense per unit of product would be substantially the same in each of these factories, as would be the total cost. Now suppose that business suddenly falls off to one-third of its previous amount and that the manufacturer shuts down the plants in Albany and Buffalo, and continues to run the one in Chicago exactly as it has been run before. The product from the Chicago plant would have the same cost that it previously had, but the expense of carrying two idle factories might be so great as to take all the profits out of the business; in other words, the profit made from the Chicago plant might be offset entirely by the loss made by the Albany and Buffalo plants.

If these plants, instead of being in different cities, were located in the same city, a similar condition might also exist in which the expense of the two idle plants would be such a drain on the business that they would offset the profit made in the going plant.

Instead of considering these three factories to be in different parts of one city, they might be considered as being within the same yard, which would not change the conditions. Finally, we might consider that the walls between these factories were taken down and that the three factories were turned into one plant, the output of which had been reduced to one-third of its normal volume. Arguing as before it would be proper to charge to this product only one-third of the indirect expense charged when the factory was running full.

If the above argument is correct, we may state the following general principle: THE INDIRECT EXPENSE CHARGEABLE TO THE OUTPUT OF A FACTORY

BEARS THE SAME RATIO TO THE INDIRECT EXPENSE NECESSARY TO RUN THE FACTORY AT NORMAL CAPACITY, AS THE OUTPUT IN QUESTION BEARS TO THE NORMAL OUTPUT OF THE FACTORY.

This theory of expense distribution, which was forced upon us by the abrupt change in conditions brought on by the war, explains many things which were inexplicable under the older theory, and gives the manufacturer uniform costs as long as the methods of manufacture do not change.

Under this method of distributing expense there will be a certain amount of undistributed expense remaining whenever the factory runs below its normal capacity. A careful consideration of this item will show that it is not chargeable to the product made, but is a business expense incurred on account of our maintaining a certain portion of the factory idle, and chargeable to profit and loss. Many manufacturers have made money in a small plant, then built a large plant and lost money for years afterwards, without quite understanding how it happened. This method of figuring gives a clear explanation of that fact and warns us to do everything possible to increase the efficiency of the plant we have, rather than to increase its size.

This theory seems to give a satisfactory answer to all the questions of cost that I have been able to apply it to, and during the past few months I have laid it before a great many capable business men and accountants. Some admitted that this viewpoint would produce a very radical change in their business policy, and are already preparing to carry out the new policy.

It explains clearly why some of our large combinations of manufacturing plants have not been as successful as was anticipated, and why the small, but newer plant, is able to compete successfully and make money, while the combinations are only just holding their own.

The idea so prevalent a few years ago, that in the industrial world money is the most powerful factor, and that if we only had enough money, nothing else would matter very much, is beginning to lose its force, for it is becoming clear that the size of a business is not so important as the policy by which it is directed. If we base our policy on the idea that the cost of an article can only legitimately include the expense necessarily incurred either directly or indirectly in producing it, we shall find that our costs are much lower than we thought, and that we can do many things which under the old method of figuring appeared suicidal.

The view of costs so largely held, namely, that the product of a factory, however small, must bear the total expense, however large, is responsible for much of the confusion about costs and hence leads to unsound business policies.

If we accept the view that the article produced shall bear only that portion of the indirect expense needed to produce it, our costs will not only become lower, but relatively far more constant, for the most variable factor in the cost of an article under the usual system of accounting has been the "overhead," which has varied almost inversely as the amount of the product. This item becomes substantially constant if the "overhead" is figured on the normal capacity of the plant.

Of course a method of accounting does not diminish the expense, but it may show us where the expense properly belongs, and give us a more correct understanding of our business.

In our illustration of the three factories, the cost in the Chicago factory remained constant, but the expense of supporting the Buffalo and Albany factories in idleness was a charge against the business, and properly chargeable to profit and loss.

If we had loaded this expense on the product of the Chicago factory, the cost of the product would probably have been so great as to have prevented our selling it, and the total loss would have been greater still.

When the factories are distinctly separate, few people make such a mistake, but where a single factory is three times as large as is needed for the output, the error is frequently made, with results that are just as misleading.

As a matter of fact it seems that the attempt to make a product bear the expense of plant not needed for its production is one of the most serious defects in our industrial system to-day, and farther reaching than the differences between employers and employees.

The problem that faces us is then first to find just what plant, or part of a plant, is needed to produce a given output, and to determine the "overhead" expense on operating that plant or portion of a plant. This is primarily the work of the manufacturer, or engineer, and only secondarily that of the accountant, who must, as far as costs are concerned, be the servant of the superintendent.

In the past, in almost all cost systems the amount of "overhead" to be charged to the product, when it did not include all the "overhead," was more or less a matter of judgment. According to the theory now presented, it is not a matter of judgment, but can be determined with an accuracy depending upon the knowledge the manufacturer has of the business.

Following this line of thought it should be possible for a manufacturer to calculate just what plant and equipment he ought to have, and what the staff of officers and workmen should be to turn out a given profit.

If this can be correctly done, the exact cost of a product can be predicted. Such a problem cannot be solved by a cost accountant of the usual type, but is primarily a problem for an engineer, whose knowledge of materials and processes is essential for its solution.

Having made an attempt to solve a problem of this type, one of the most important functions we need a cost system to perform, is to keep the superintendent continually advised as to how nearly he is realizing the ideal set, and to point out where the shortcomings are.

Many of us are accustomed to this viewpoint when we are treating individual operations singly, but few have as yet made an attempt to consider that this idea might be applied to a plant as a whole, except when the processes of manufacture are simple and the products few in number. When, however, the processes become numerous or complicated, the necessity for such a check becomes more urgent, and the cost keeper who performs this function becomes an integral part of the manufacturing system, and acts for the superintendent, as an inspector, who keeps him advised at all times of the quality of his own work.

This conception of the duties of a cost keeper does not at all interfere with his supplying the financier with the information he needs, but insures that information shall be correct, for the cost keeper is continually making a comparison for the benefit of the superintendent, of what has been done with what should have been done. Costs are valuable only as com-

parisons, and comparisons are of little value unless we have a standard, which it is the function of the engineer to set.

Lack of reliable cost methods has, in the past, been responsible for much of the uncertainty so prevalent in our industrial policies; but with a definite and reliable cost method, which enables us to differentiate between what is lost in manufacturing and what is lost in business, it will usually become easy to define clearly the proper business policy.

DISCUSSION

In presenting his paper at the meeting the author introduced it with the following remarks:

I was moved to present this paper not because the ideas were absolutely new, but because they are of such great importance to manufacturers, and are apparently so little understood by many of them.

Since publishing this paper I have had my attention called to the work of numerous accountants, and especially manufacturers, who, within the last few years, have discarded tradition, and made excellent progress toward a rational system of expense distribution. Some have apparently solved the problem completely. Nevertheless it is a fact that the generally accepted theory of only a few years ago, was that the product of a shop must bear the total expense of owning and operating that shop. It is also a fact that this theory is still misleading many manufacturers. In addition, the expense of selling was often added as a part of the cost of the article.

The first step taken by students of this problem was to separate the cost of manufacturing from that of selling. According to this division, the expense of manufacturing stops when the article is delivered to the shipping department or placed in the finished stock room. All expenses incurred from this time on belong to the sales department and are deductions from profits.

This separation took one variable and confusing element out of the manufacturing cost; but with a widely varying product and a relative fixed "burden" or "overhead" charge, the manufacturing cost was still subject to fluctuations over which the superintendent had no control, and hence not only gave no measure of the efficiency with which the shop was run, but was no guide at all to the salesman; and was actually misleading when business was dull.

The next step in the evolution of a rational cost system was to establish a fixed "overhead" based on past experience. This had the great advantage of making costs comparable, and of giving the salesman a definite limit by which to be governed.

It had the disadvantage that if the output was at a less rate than the usual previous rate, there was left unabsorbed a portion of this "overhead;" and vice versa, if the product was greater than at the previous average rate more "overhead" was accounted for than was actually incurred. Of the various methods adopted to take care of this residual "overhead," the two that are best known are, first by charging it to a fund that is eventually charged back on the cost of the product, and second by charging it directly to business as a profit or loss. The second method seems the most logical of the two, and for those who are guided only by what has been done in the past, seems to be entirely satisfactory. Indeed for him who is an accountant only, and not familiar with

manufacturing methods, it is apparently the only possible solution.

To the engineer, however, who is not so much concerned with *what has been done* as with *what should be done*, it is not at all satisfactory.

If a plant has been built that is larger than is needed to supply the available market, the business error of building the excess portion of that plant should not be charged as a manufacturing cost, but directly to the business as a loss. For instance, if we should build two identical plants where only one was needed, the expense of owning and maintaining one of them in idleness could not be charged to the goods manufactured in the other, but would have to be deducted from the profits of the business.

In the same way the expense of any portion of a plant not needed in production should not be charged to the articles produced, but is a business expense and must be deducted from profits, or entered as a loss, if the profits will not cover it. *In other words, the only expense logically chargeable to a product is that needed for its production when the factory is running at its full or normal capacity, which may be quite different from that used in its production in the past.*

Inasmuch as the determination of this fact is primarily an engineering or manufacturing problem, and not primarily an accounting problem, it becomes evident that cost methods must be based on engineering knowledge, and the cost accountant of the future must himself be an engineer or manufacturer, or be guided by one.

Granting this, it is safe to predict the early dawning of the day longed for by Uncle John Sweet, when *the man who knows what to do and how to do it* shall gradually supplant *the man who knows what was done and who did it*.

D. B. RUSHMORE. Speaking entirely from an individual standpoint, I would say that all of my experience points to the fact that free industrial competition in general means nothing but final bankruptcy. This is because of certain elements of human nature which, for a great variety of reasons, allow business to be taken by someone below cost.

In figuring the cost of any product the largest and most indeterminate item is usually the overhead expense, and the proper use of this overhead after it is once obtained is of course the difficult part of the problem. The manufacture and production of power and commodities is usually subject to considerable fluctuations, and in the extreme case of a small power house for a widely fluctuating load, in which the power may vary from zero to a maximum over irregular intervals, the instantaneous cost of power will vary enormously. These fluctuations may be momentary, hourly or even annually, and the proper distribution of the overhead in order to determine the average cost is necessarily a problem requiring judgment.

The year has usually been taken as the unit of time. The question is, can this period be enlarged so as to include an average of several of the past years, and can these figures be used in an attempted prophecy of the future. It would certainly seem as if this were a feasible and sensible point of view.

FORREST E. CARDULLO. I think the idea advocated in the paper is correct, but there are two points to which I would call attention: One is that the loss incurred and charged to profit and loss must be made up in the selling price. The

other one is the question as to whether it is better to charge that loss annually against the product, or to capitalize it and get rid of it once and for all.

W. N. POLAKOV. The question is, whether the cost at which a product has been manufactured in the past is the cost at which this product shall be and can be manufactured. If the overhead is not properly differentiated from the cost of production; and if the cost of production is not known,—not as it was in the past, but as it ought to be,—we shall not be in a sound position.

To quote an example, there is an electric plant which carried \$200,000 overhead a year. The records show that the plant generated current at between 0.72 and 0.68 cent per kw., depending on the load factor.

If with an annual output of 60,000,000 kw-hr. (or about half capacity), the overhead charges were distributed per kw-hr., it would be $\frac{1}{3}$ cent; if the output were 80,000,000, the overhead would be $\frac{1}{4}$ cent and if there were a full output of 120,000,000, allowing a margin for peaks and breakdowns, the overhead would be 0.166 cent.

Consider at the same time that the capacity of the plant may not have been sufficient for the increased business and that a public utility company was willing to sell any amount of current for 0.83 cent per kw-hr. One would immediately, in accordance with the old method, go to the old records and get the lowest figure, 0.68 cent, for which current had been manufactured, and then add the minimum overhead of 0.166 cent, giving 0.85 cent instead of the 0.83 cent which the public service corporation offered. On this basis one would seem to be warranted in buying the current, at least for the present, because of the saving of 0.02 cent on every kw-hr. When new records are compiled, it would be found that the cost of production of the plant in question had risen to 0.91 cent because the output was reduced and the overhead was 0.25 instead of 0.166. We finally come to the point where we think there is no use of carrying our plant any longer, so it is shut down and all the power purchased outside at 0.83 cent.

If this were done it would mean that we would get the power at 0.83 cent, plus the overhead on the dead plant of \$200,000. In this case the cost per kw-hr. would be 0.996 cent, and we would then remember that while the plant was in operation current had been manufactured for 0.85 cent. Where would be the expected saving? It apparently was there,—it was on the books, but it appears to be lost. Where has it gone? One fallacy of such calculations is that we use the past records instead of the exact scientifically established standard of what the cost ought to be. In fact, in this case it ought to be only 0.4, as I know from actual experience that the cost was brought down in this plant from 0.72 to 0.44, which, added to the overhead even in accordance with the old method, would be only 0.6, consequently the expected saving of some \$25,000 on the plan of buying power would be turned into a loss for the company of over a quarter of a million dollars.

W. W. BIRD. This paper is of special interest to me as it indicates in a way the evolution of the mechanical engineer. Twenty or thirty years ago we came to the meetings of this Society and we heard Thurston talk about the steam engine indicator. The mechanical engineer of those days made boiler and engine tests. Ten years ago we heard Taylor tell

about the stop watch and routing cards for workmen. The mechanical engineer of that period not only went into the power house of an industrial plant, but also into the shop. The engineering thought as expressed by the planning department was carried out in the shop just the same as the ideas as expressed by the blue prints from the drafting room were followed.

Now Gantt comes along and tells us that it is not good engineering to put all of the shop burden on productive labor all of the time. In other words, the mechanical engineer of today is applying the general principle of cause and effect in the office of our industrial plants the same as he has in the other departments.

At the Worcester Polytechnic Institute, we are working along these lines and our students have laboratory work in the office of our commercial shops just the same as they do in the steam and other laboratories.

Good engineering is needed in the accounting department and I am very glad that the author has presented this paper for our consideration. We ought to tackle this problem of

application to such a concern as a gas company, whose fixed charges can be accurately determined.

CONTRIBUTED DISCUSSION

CHARLES PIEZ. No matter to what degree of refinement a cost keeping system may be carried, costs are, at best, but fairly accurate approximations, and to be even that must represent averages over long periods. If the costs are to be used as the basis of selling quotations, they should be based on normal and not on exceptional conditions.

Too many manufacturers still sell at what they assume to be the market price, in the hope that ingenuity and rigid economy will let them out at a profit. But permanency in business will never be the lot of the manufacturer who permits the buyer to name the price and who does not fortify his position by a thorough knowledge of costs.

With the wide fluctuations to which manufacturing is unfortunately subjected, it is essential that a fairly accurate determination be made of what normal capacity, normal expense and therefore normal costs are; very few factories run uniformly at 100 per cent capacity; a great many vary in the course of a business cycle from 50 per cent capacity in times like the present, to 150 per cent capacity in boom times. Not only is there wide variation in total output, but departments frequently show great variations independent of general business conditions.

As a rule, a manufacturing enterprise whose business shows considerable fluctuation must have a capacity slightly in excess of the normal or average requirements if prompt service to the customer is necessary.

In our own business we have assumed normal output to be the output of each department secured by its full complement of men working 2500 hours per year which represents 90 per cent of the possible working hours per annum on a 54-hour week basis.

The average factory expenses are distributed on a pay roll representing this degree of activity and our average or standard departmental and general expense factors are based on the output which this degree of activity represents. Costs are based on the average factors, and are therefore fairly uniform and wholly independent of the fluctuations of business.

At the end of each month the standard or average factors are compared with the actual factors for each department and the total of all expenses is compared with the total obtained by distributing the standard rates. In times of depression the standard rates fail to distribute the total expenses and the debit balance goes to reduce the profits. When the business is running considerably above the assumed normal the standard factors produce a credit balance which goes to increase the profits.

The sheets showing the comparison between actual and standard expense rates, which the cost department submit to the management each month, keep the management informed and enable it to correct the standard rates when changed conditions render corrections advisable. By following the method of distributing expenses through carefully ascertained standard factors, we secure in a ready and practical way the results which the author advocates.

In this connection it might be well to point out the opportunity for a valuable service which the Society might render not only to its members, but to the manufacturing community

FIG. 1. DIAGRAM SHOWING RELATION OF FIXED CHARGES, PRODUCTION COST AND INCOME

shop burden the same as we would one in power transmission. Let productive labor carry that part of the burden for which it is responsible and can regulate, and let the men higher up do the same.

The responsibility of our manufacturing plants should not be divided. Starting from the top, responsibility should be delegated and definitely placed and then if a plant cannot be made a success, let the self executing laws of nature do their work and put the plant out of existence.

JAMES A. WHITE showed a diagram, Fig. 1, which he had found useful in determining the effect of fixed charges. Assuming that it is known what the fixed charges are, a line is drawn to represent them as indicated. Above are added lines to represent labor and material costs, which vary with the output. A fourth line represents sales income, which varies directly as the amount of business done, and starts at the zero point of the diagram. The point where the sales income line crosses the total cost line indicates where it is advisable to shut down the factory; the shaded space at the left indicating loss, and the upper space at the right, profit. This diagram is difficult to apply to a factory, but it is easy of

at large. The Society has the honor of having recommended several mechanical standards, which have had universal adoption. Would it not be wholly within its province to give the subject of expense distribution in mechanical plants some attention, and make recommendations for the standardization of such distribution?

There can be no real comparison of costs unless there is uniformity in cost accounting; neither will violent fluctuations in prices in times of depression cease until uniform and standardized systems of expense distribution take the determinations of costs out of the realm of conjecture and place it on a firm foundation of ascertained facts.

FRANK H. NEELY. This paper does much to clear up the uncertainty with which most manufacturers consider indirect expense and its application to costs. Further, it shows in clear relief the urgent need of the engineer in laying out and deciding upon the business issues of manufacturing.

In times such as we are just passing through, the idea of making money has to give way to the idea of the preservation of a working organization and of taking care of the workers who in good times past have helped make the profit, and who, if the author's idea is followed out, will have a great deal of work that would otherwise have gone to factories not so apparently loaded down with indirect expense.

About three years ago, in standardizing the processes in a factory making a complete line of candies and crackers, I found it necessary to develop my cost records very much along the line of the author's paper. This business is seasonal, and in the three fall months the volume is practically double what it is in any other similar period in the year.

This, of course, made the costs appear high in the first part of the year and extremely low in the busy season, which forced the standardization of costs on the lines described in the paper for the individual product; and each department, as the year progresses, shows its profit or loss, at the same time absorbing its just pro rata of indirect expense, regardless of the volume manufactured.

STERLING H. BUNNELL. The reason why cost systems are generally of so little use to the manufacturer is that they are planned for no other purpose than to meet the needs of the accountant in balancing his books. The fact that cost keepers are accountants and not manufacturers is the only explanation of the belief so prevalent that the cost of the product of a given month is equal to the total expenditure of the month.

The fact is, that the cost of to-day's product is the result of the whole past existence and future purpose of the factory organization. Experience is expensive before it becomes a direct source of profit; equipment, working force, financial resources and goodwill all enter into the cost, not only of the factory product of to-day, but also of the product of future days and years. The cost of the day's product, therefore, includes more than the chance portion of the total cost of operating the plant that happens to get into the day's accounts.

Cost records are expensive, and, therefore, have no reason for existence if not practically useful. They should show the works management that the cost of product is within its proper standards. For this purpose, the items of material and direct labor are sufficient, and the burden figure of secondary importance. But the cost figures should also show the

sales department the minimum selling prices which will cover the total of operating cost. Material, direct labor and factory burden furnish only part of the total which selling price must cover in order to insure continued profit.

The determination of this extra overhead necessary to maintain an average of profit is the great problem of factory accounting. The tools in continuous use must carry the expense of those which may be idle, and the busy years must earn the profit for the times of bad trade. The reservation of a surplus, to provide stability of dividends, is generally approved. In an unprofitable year, the unearned dividend may then be paid from the surplus. The use of an account for unearned burden, and offsetting this deficit by a proper increase in the general overhead rate, is exactly parallel. Every lost minute of operation causes a loss in earnings. If idle tools are necessary incidents of the business, the losses on them must be made up from the general income of the plant, or a deficit will result. This accords with the principle set forth by the author. The time lost in the factory operation must in the end be paid for by a mortgage on the busy hours; but there is no reason why the mortgage should be foreclosed immediately by writing off the whole cost of operation against the product of the lean month, when that would involve selling at an apparent loss.

It is indeed surprising that there are business men who do not seem to realize that high efficiency is more profitable than surplus capacity. As the charges on idle equipment must be carried by the equipment which runs, there should be just as little idle plant as possible. Fluctuations in demand are better cared for by increasing output with existing equipment, than by adding new tools which are likely to stand unused under average conditions. It is often easier to buy more machines than to find the causes of loss of output by the present ones. But, when the inevitable contraction comes, the management which has met demands by increasing the output of the existing plant instead of by adding equipment, is likely to be in position to continue dividends by drawing on an ample surplus.

KEPPELE HALL. The author's contention that overhead or indirect charges cannot be arbitrarily distributed over product without regard to conditions, and still have costs serve as a useful guide to the management or superintendent, is illustrated by the following example:

An electric light company in a small town was supplying current for lighting and a small amount of power. The business necessitated running the plant all day, although the day load was very light. An opportunity was offered to secure a very good day load by furnishing power to a street railway company, but the price at which the contract could be obtained was below the cost of production. This cost of production included the entire overhead expense prorated over the output. At first sight the proposition seemed undesirable; but on further investigation it appeared that, with the exception of a small amount of oil for lubrication and a negligible increase in depreciation owing to increased load, the only additional expenditure necessary to take on this business was the cost of the extra coal consumed and the removal of the extra ashes. No additional employees would be required in the power station or in the office. The contract was accepted and, in spite of the increased output, the price obtained was *below cost*. As a matter of fact the in-

come derived from this contract paid the company's entire coal bill and very handsomely increased the net profits. If this matter had been judged entirely on costs, it would have appeared a losing proposition, while as a matter of fact, it proved a dividend payer. Of course, this business could only be considered feasible as long as the demand for the higher priced lighting current did not encroach on the reserve capacity of the plant.

An objection that might be raised against the author's proposed solution of overhead expense distribution is that it does not hold the superintendent responsible for such items of the indirect expense as he has under his control during slack times. For example, suppose the normal output is 100 and necessary indirect expense is \$100. If the output drops to \$50 and the indirect expense to \$80, the output would be charged with \$50 and the remaining \$30 would be thrown into a profit and loss or business account. How are we to know whether or not the superintendent is rightly responsible for a portion of that \$30, which he might have saved? In such a case is it not advisable to divide the indirect expense, hold the product responsible for such portion of it as the superintendent can control, and relieve it of that portion over which he has no control?

It would appear that task work has a very important bearing on the subject of accurate costs. Where tasks have been scientifically set, and where the proper amount of material has been determined upon, the superintendent's chief responsibility is to see that, whatever the conditions of business, the work is done in the proper time and the proper amount of material is used. If this is strictly followed, any extra expense incurred on account of poor business conditions is not the superintendent's responsibility.

A good arrangement for proportioning indirect costs is to have a machine or work place rate fixed so as to cover all indirect expense under normal conditions. Each job is then charged with the direct labor and material and the machine or work place hours. The balance of the indirect expense, which is not absorbed by the machine and work place rates, is placed in an account known as an under-absorption account. This account increases in dull times and decreases in very busy times. The net result at the end of a given period shows the under or over-absorption of the indirect expense. The cost of the product is estimated from the sum of the three items (labor, material and machine or work place hours), and, except for variations in the efficiency with which the work is done, holds the costs practically constant. An account of this kind is very useful in equalizing costs over periods of slack production which are apt to occur in almost any business. It also serves to equalize unusual expenses which in some processes are incurred at certain periods of the year, such for example as with a product which requires a large amount of steam in cold weather and practically none in warm weather. This arrangement distributes this unusual expense over both periods and tends to equalize the cost.

A matter, which is not given the importance it deserves in management, is the fact that it is possible to regulate almost any business so there will be no great variation in output due to seasonal demands for the product or variations in the condition of business. Proper management should make an effort to control these conditions and has done so in a number of cases.

For example, a concern manufacturing automobiles has

standardized its output so that it does not vary from one year's end to the other. This has been accomplished by offering special inducements to agents to dispose of the product during the dull season and also by manufacturing its product during this season, except some of the more expensive parts which can be put on in a comparatively short time, and holding this product until the seasonal demand arises.

CARL G. BARTL. The question Mr. Gantt endeavors to answer in his paper is only another form of the old question of how low we may take orders in dull times, and it does not seem to me that he has reached the bottom of it.

The true answer to the question may be made no matter what the policy of a concern regarding the distribution of its overhead expenses, so long as these are definitely known and properly analyzed.

This is by means of what Mr. Taylor called dull time "limit costs," the making up of which is practised by all concerns which fully understand the true nature of manufacturing costs.

In very dull times it is unfortunately not so much a question of how much money we can make by taking orders, but how to manage so as to hold an organization together and to lose as little money as possible, for the fixed charges go on even if we take no orders at all and allow the organization to disband.

In making up a "limit cost," we therefore leave out all consideration of the fixed charges of a plant, and also such other overhead expenses as, without being absolutely fixed, become so for the time being, because we purpose not to disrupt our organization entirely.

The overhead expenses to be added to flat labor and material in making up a limit cost are, therefore, such only as will actually be incurred by virtue of undertaking the work under consideration.

If this limit cost is less than the market value of an article it will then be correct to manufacture the article ourselves rather than to buy it, or to offer it in the market for anything, however little, over and above this limit cost, for this margin will help carry the fixed charges.

Suppose the limit cost of the article in the case cited in the paper could have been shown to figure up to 20 cents only, this would have constituted a still stronger argument against the buying of the article at 26 cents, even if the full and true cost at the time of manufacture was 30 cents.

R. E. FLANDERS. In the firm with which I am connected the plan is followed of setting the overhead rate to agree with average business conditions over a long period, taking into account both good times and bad. An overhead account is carried, to which are charged all the items that go to make up the shop overhead expense; and in like manner to this account are credited all sums apportioned as overhead charges to work in process.

In busy times there will evidently be a deficit in this overhead account. In dull times, on the contrary, the continuance of the heavy expenses, coupled with the small volume of productive labor to which they may be applied, will produce a heavy unapportioned balance in the account. The plan is so to set the average overhead rate that the deficits and excess balances will about cancel each other. From time to time this overhead rate requires adjustment to meet

changed business conditions, both internal and external. These changes are, however, neither frequent nor violent.

This plan, without doubt, is used by many other concerns besides my own, all of which have doubtless been led to adopt it for substantially the same reasons. It is worth while, therefore, to compare this plan, which we may call the *average rate* plan, with that set forth by the author, which we may call, for simplicity, the *proportional rate* plan.

In the first place, the average rate, being practically unchanging, is the more easily applied.

The average rate has the same advantage as the proportional rate in the matter of avoiding sudden and violent fluctuation in the cost figures due to corresponding fluctuation in the output.

The average rate offers the most direct method of distributing what may be called the "cataclysmic" overhead expenses. In this category are included such items as taxes, etc., which impose a disastrous load on the period in which they fall, unless they are apportioned piecemeal over the full term to which they apply.

The main difference between the two plans is that with the average rate the burden of carrying idle equipment and organization through dull times is distributed into the cost of work in good times, while the proportional rate takes it out of the cost system entirely and charges it to profit and loss.

Now, I contend that there is good reason for absorbing this periodically recurring expense in costs, rather than in profit and loss. This charge has not the nature of an extraneous calamity, like an embezzlement or unwise investment. We are forced, unfortunately, to reckon with cycles of boom and depression as one of the conditions of doing business in this country. This condition is therefore a regular factor in the cost of production, and should be so treated.

This argument becomes all the stronger when it is remembered that cost figures have a two-fold use. Not only are they employed for comparison with previous costs, but they are used as well to determine whether articles can be profitably manufactured at a given selling price; in some cases, in fact, they are used for setting selling prices. There is nothing like having all unavoidable expenses firmly imbedded in the cost figures, instead of allowing them to rattle around loose in the ledger.

To sum up the matter, it may be said that the use of the average rate directly disagrees with what the author states as a fallacy, that *all of the expense, however large, must be carried by the output produced, however small*. In fact, it seems to me to be the prime merit of the average rate plan, when based on an overhead account, that no legitimate expense escapes from distribution to costs. The errors which the author sees in this principle are not inherent in the principle at all, but are caused by an illogical application of it. The *average rate* seems to me to answer all, or nearly all, of his objections.

The proper solution of problems such as outlined by Mr. Gantt, of a factory running below normal capacity, is independent of any particular method of applying overhead charges. You can increase its output without perceptibly increasing the overhead charges, and you may safely reckon the cost of the increased production as equal to labor plus material only. Forget about the overhead. Any margin between the cost and the price at which you can buy or sell may be considered as profit, in the sense that it will, by that much,

help to carry your overhead and thus reduce your expenses. This is not a matter of accounting, but of common sense.

In his discussion of the effect of the size of a plant and of a business the author opens up a line of thought which leads to interesting conclusions as to the ideal size of plant. That size, for a concern manufacturing staple articles, would seem to be such as to be able to take care of some reasonable percentage over the minimum demand in dull times. A plant so proportioned, with reserve and credit good enough to run full and build a fair stock in dull times, could be operated with the minimum attainable overhead rate. It would therefore capture practically all of this dull time business, and get, as well, the maximum profit on its output in good times, if it were well managed otherwise. In fact, the greatest danger to such a business would be the ever-present temptation to expand—a temptation which, if yielded to, might entirely undermine the foundations of its prosperity.

D. C. FERNER. Mr. Gantt's interesting paper suggests hope for a branch of cost accounting that is still struggling for intelligent analysis and even a semblance of uniformity. I refer to a proper determination of the cost of operating motor trucks. Every alternate step in production, conversion and distribution of any product is that of transportation. Raw stock, stock in process, finished stock must be moved on to the ultimate consumer. At many points motor driven road trucks, shop trucks, crane trucks, tractors and trailers can be used to advantage, but comparatively few managers can see the necessity for making the change. Present methods are built around equipment very limited as to capacity and sales value, but strong in associations, sentiment and book valuation. Depending on how good a horse trader the stable boss may be, the manager figures he can use horses and hand trucks for several years to come. He hesitates to adopt machine equipment on account of its initial cost, and its cost of operation. He has never kept accurate costs of horse delivery and the very limited amount of machine costs that are available are based on conditions that do not fit his business. He finds too that each machine is loaded with a fixed portion of the yearly overhead charges of the installation, whether the particular machine has been in operation all or a portion of the time. In other words a fixed charge is made against each machine working or idle and at the end of the year the total fixed charges for the year have figured prominently in the "cost of operation per mile" or per ton.

Following the author's suggestions, if a motor truck is laid up for lack of work its fixed charges or overhead for that period should be charged against profit and loss, and it should be up to the manager to find outside work for his trucks.

Going still further, if a motor truck is laid up for repairs, the fixed charges for that period of time should be added to the cost of repairs, and should not appear as fixed charges against the actual cost of operation.

By a proper analysis of operating and maintenance costs, the manager can always find a guide for reducing the idle time and increasing the earning capacity of each individual machine and the installation as a whole.

C. BERTRAND THOMPSON. One important purpose of factory cost accounting is to provide a basis of comparison of

the cost of production from one period to another. Obviously, for this comparison to be of any value, the items to be compared must be based on similar conditions; or if this is impossible, the varying factor should be isolated in such a way that its influence may be separately considered.

A normal manufacturing cost is that which is accurate when the plant is running at its normal capacity, and this should be made the basis for comparison. Therefore, if the plant is not running at its normal capacity, the factor of idle time must be kept account of separately if comparisons are to be of any value.

The conclusion from these considerations is that in periods of depression and subnormal operation, costs should be figured on the basis of the equipment actually used, and the cost of idle equipment should be determined and charged simply in the profit and loss account, to be taken care of in the selling price so far as competitive conditions permit.

Mr. Gantt notes that this method may affect the policy of the plant, but unfortunately does not offer a suggestion as to what the new policy should be. Merely charging the cost of unused plant and equipment to profit and loss does not really solve the problem, which is—How can this loss be made good? When it is a question of closing whole plants there is a possibility of selling them and thus at least cutting off a part of the loss; but when it is a question of part of a plant being unused it is practically impossible to end the loss by merely disposing of the superfluous part.

One suggestion offered is to take the possibility of subnormal operation into account in setting the normal selling price. This is good so far as competition permits and so far as only average deviations from normal operations are anticipated. It cannot, however, take care of long continued abnormal conditions such as we have been experiencing. Viewed broadly, the condition of subnormal operation in a plant is due to the sales organization rather than the producing organization, not overlooking the fact that the sales organization has a perfectly legitimate excuse for not keeping the plant busy up to its fullest capacity. In view of this fact, the producing organization should not be penalized for the lack of opportunity to produce.

The excess cost should not of course be charged to the sales department any more than to the producing department. Special emphasis nevertheless, should be laid on the fact that it rests on the sales organization to reduce or eliminate the loss.

Here is a field for a further application of scientific management. Thus far this type of organization has been limited almost exclusively to production, and there it is doing extraordinarily effective work. Its successful practitioners in this field ought not to be expected to undertake the considerably different problem of distribution. But there is a clear call for the application to the marketing problem of the same type of analysis, scientific research and accurate determination of laws and principles that has characterized the development of scientific management in production.

WILLIAM KENT. Mr. Gantt's paper is an admirable presentation of the evils that result from the adoption of a system of costkeeping, usually advocated by accountants, in which all the indirect expense, burden, or overhead, in a given period of time, such as a month, is charged as part of the cost of the output of that period, even if the amount of

that output, on account of depression of business or other cause is far below normal. The only excuse for such a system is an accountant's one, that it enables the cost ledger to be balanced each month.

Mr. Gantt's statement of the general principle or theory of the correct method of charging indirect expense against product is strictly sound and logical, but it is not a new theory or principle. I have been acquainted with it and have believed in it for many years, although I do not recall that I have seen it in print. I have often made a statement of the principle something like this: "The burden to be charged against any product is the average burden of a normal year for the same quantity of product. If the total cost of keeping a certain machine in a shop for a year, including cost of light, heat, power, repairs, depreciation, rent, etc., divided by the number of hours the machine may be expected to run in a normal year is say 20 cents per machine hour, then the charge for burden to be made against the product of that machine is fixed at 20 cents per hour for the time the machine runs in the following year, whether it runs the normal number of hours or not."

In this connection attention may be called to an example of incorrect reasoning which sometimes follows a strict adherence to distributing burden on the machine hour system. An owner of a machine shop who had a tabulated hourly burden charge for each machine, varying with the size of the machine, the cost of running it and the number of hours that the machine was expected to run in a year, noticed that a small piece was being turned in a very large lathe. He told the foreman that he should not use the lathe for that piece because the burden charge on it was too heavy, and it would make the piece cost too much. The foreman replied that all the other lathes were busy and that there was no heavy work on hand for the large tool, and he thought he would make the big lathe "do something for its keep." The foreman was right, and, moreover, the burden that should be assessed against that piece in making up its cost, if the cost was to be used as a basis for estimating on future orders for similar pieces, is not the machine hour rate of the big lathe, but only that of a small one, on which the work would ordinarily be done.

THE AUTHOR. If I am to draw any conclusions from the discussion of this paper, it has had the effect which I hoped it would have, namely, to make clear that a cost accountant to be really useful to a manufacturing company must understand the manufacturing process.

There is one point, however, which does not seem to have been clearly grasped by some, and that is that what I propose as the real cost of an article is not what it apparently has cost in the past, but what it should cost if the proper manufacturing methods were used and the shop were run at full capacity. This might be called the *ideal cost*, and toward its attainment all efforts should be directed. Mr. Polakov's discussion illustrates this most clearly.

It was perhaps twenty years ago when the great necessity for a knowledge of costs began to be apparent, and manufacturers in general began to give the subject careful consideration. The demand for "cost accountants" soon became so great that almost any clerk who had had experience in a manufacturing plant was able to get a job as cost accountant, much as, today, almost anybody who calls himself an "efficiency engineer," even though he may never have had any

engineering experience whatever, seems to be able to gain the confidence of some manufacturer.

Such cost accountants, with a few high-sounding theories and a little bookkeeping experience, but with absolutely no shop knowledge, have too often been able to gain the confidence of the financier, whose policy has been governed by the reports obtained from such sources. The result of such an epidemic of cost accounting has undoubtedly been seriously detrimental to our industries, and it is with a great deal of satisfaction that I see the best accountants of today absolutely repudiating false theories and, if not actually keeping pace with engineers on the subject, at least traveling the same road.

The class of people that advertised themselves as "cost accountants" when "costs" was the watchword, today follow the slogan of "efficiency." This is certainly a step in advance as far as their work is concerned, but before we sacrifice everything on the altar of "efficiency," let us ask whether efficiency is a *means* or an *end*, and get the answer.

It is our duty to ourselves and to society to do well, or efficiently, whatever we do but are we not in danger of losing sight of our object if we lay too much stress on the efficiency with which we strive for it?

It does not take much thought to convince us that *efficiency* is not an *end*, but a *means*; and that it may be beneficial or detrimental as the end is worthy, or unworthy.

To do efficiently something that should not be done at all, benefits nobody. Would it not be better to do something worth while, however inefficiently? Let us stop, therefore, in this wild cry for efficiency long enough to ask what its proper aim is.

If its object is to enable the few to accumulate wealth at the expense of the many, it is not worth while, for an industrial system that allows this will finally fail. If its aim is to enable one man to take unfair advantage of another in any manner it is not suitable to a democratic nation; and it is the country as a whole that must be considered, when we discuss such a broad question as this.

The greatest problem before our industrial world today is the establishment of harmonious coöperative relations between employer and employee. Efficiency is one of the most potent factors in the solution of this great problem, but it can be directed either for or against this solution.

Should we not know on which side it is to be used before we commit ourselves to it?

Before we support too strongly, then, this striving for efficiency, let us be sure that it is to be directly toward a worthy object. Efficiency alone will not cure our troubles, for misdirected efficiency *may be* just as detrimental in the future, as misdirected *cost accounting* has been in the past.

On the other hand, a combination of properly directed efficiency and proper cost methods are absolutely essential to the solution of our industrial problems; and the hopeful thing about the newer ideas of cost keeping is that they point the way of measuring not only the efficiency of the workmen, but that of the manager and of the financier.

Past methods have too often not only failed in this respect, but have frequently been so devised as to relieve the man at the top of the responsibility that was justly his, and to saddle it on the subordinate. The introduction of methods that will relieve this situation will be a long step in the solution of our industrial problems.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

There are still some people inclined to make a distinction between theory and practice. An article abstracted in the present issue brings a rather striking illustration of the fact that of late such a distinction is rapidly losing its sense. On the face of it, an investigation into the velocity of reaction in chemical processes belonging to what is known as physical chemistry, would appear to be "highly theoretical" and quite removed from "practice" and yet here we have a description of an entirely practicable and apparently valuable process for the production of hydrogen, based exclusively on the knowledge of facts derived from an investigation into the velocities of reaction at various temperatures as affecting the relative inertia of chemical processes.

THIS MONTH'S ARTICLES

The analysis and testing of explosion engine fuels are extensively discussed in an article in a German periodical.

Data of tests on air permeability of various building materials are reported, including such comparatively recent materials as chalky sandstone and perforated bricks.

The theory of resistance of rolling a hard body over a plastic surface is reported from an article in a Russian technical periodical, where also are given data from tests on the power consumed by wheels equipped with metal tires rolling over soft ground, of the power consumption in pure rolling of an American caterpillar tractor and the economy obtained in transporting heavy pieces of artillery by the use of the so-called Bonagente band.

An automatically operating refrigerating apparatus of Swiss design is described in considerable detail.

In the section on Steam Engineering is described a special system of replacing boiler tubes, which not only allows of the use of old tubes over and over again, but makes a joint between an old tube and the boiler actually stronger than one between the boiler and a new tube to which this method has not been applied. In the same section are discussed methods of calculation of safety valves with high lifts. The author shows that the so-called Cario formula for safety valves with high lift does not apply in the case of high efficiency boilers, and quotes tests showing that with valves dimensioned in accordance with that formula, the steam pressure may, under certain conditions, exceed the maximum permitted limit. A process of calculating de Laval nozzles by means of the PV diagram is reported from a German periodical.

From the Journal of the American Society of Naval Engineers is abstracted a paper on heat transmission and tube length in marine feed water heaters, by Leo Loch. Particular attention is called to this paper both on account of the experimental data reported and very interesting theoretical considerations presented by the author.

Some fallacies in cement testing are discussed by W. Lawrence Gadd in the Transactions of the Concrete Institute. Among other things, the author calls attention to the fact that tests of fineness of cement are apt to give erratic results because the mesh of the sieve is but seldom uniform and also because, while the mesh is specified, the size of the sieve which may materially affect the results is, as a rule (in particular

in the British Standard specifications), overlooked. The author likewise does not see that there is any use in the specific gravity test.

A paper by F. J. Sehlunk, on automatic scales, has been abstracted from an advance publication in the Scale Journal. It is of interest as giving a reliable classification of various types of automatic scales and describes the various fundamental principles of their construction.

The very important subject of the hardening of metals is discussed in abstract from the Transactions of the Faraday Society. While lack of space prevented the giving of more detailed abstract of the various papers presented to the Society on that subject, it is believed that interesting data will be found in the abstract of papers by Professor Ernst Cohen, of Utrecht, J. C. W. Humfrey (The Amorphous Phase in the Hardening of Steels) and Sir Robert Hadfield.

The question of the future developments in heating and ventilating is discussed by A. H. Barker, before the Society of Engineers. The author takes a rather novel view of some sides of that important branch of engineering, reports data of interesting tests and, among other things, explains certain phenomena which have been recognized for a long time but not fully understood; e.g., the unpleasant effect produced by radiator heat. The author distinguishes between temperature of air and radiant temperature, describes apparatus for measuring either of the two and attempts to throw light on some little understood phenomena by separating both the above referred to kinds of temperature.

From a bulletin of the University of Illinois are described experiments referring to the study of boiler losses.

FOREIGN REVIEW

Internal-Combustion Engineering

ANALYSIS AND TESTING OF EXPLOSION ENGINE FUELS.

The article discusses the question of the utilization of gasoline, benzol, motor spirit and other fuels in explosion engines, with special regard to automobile motors. It is very complete, covers extensive references to German publications, both books and articles, and goes fully into the question of analysis and testing.

The author points out that hitherto the sale of gasoline, benzol, etc., was mainly based on confidence in the seller and that it is only quite recently that an attempt at establishing specifications has been made. The author believes that the pleasure vehicle will use, in the future as now, real gasoline, which he calls, in this connection, "luxury" gasoline; that the commercial vehicle might use mixtures of gasoline and benzol or heavier oil generally, and that stationary engines will use the cheapest and heaviest grades.

As mentioned above, the author discusses in detail the methods of testing motor fuels, under the following heads: *a* Determination of specific weight; *b* Color and external appearance; *c* Test by smell of the filter residue; *d* Length of evaporation on a watch glass; *e* Behavior with respect to litmus paper; *f* Color reaction with sulphuric acid; *g* Qualitative and quantitative determination of aromatic hydrocarbons and unsaturated combinations; *h* Benzol test by

means of isatin and sulphuric acid, (0.1 isatin and 30 grams sulphuric acid); *j* Benzol test by nitration with nitric and sulphuric acids; *k* Benzol test by means of "dragon ruby" (a special preparation made from pitch obtained from the blood of a Sumatra palm dragon); *l* Test for the determination of coal tar, lignite, benzine and sulphur compounds by means of silver nitrate; *m* Test for water by means of calcium chloride; *n* Fractional distillation; and, *o* Investigation of fuels by refraction.

The purpose of the article is to help in establishing a standard specification for fuels used for various purposes; the author gives samples of such specifications, viz., three specifications for gasoline (light automobile grade, middle weight commercial vehicle grade, and the still heavier grade for stationary engines) motor benzol and motor spirit. *Die Analyse und Wertbestimmung der Motoren-Ben; ne, -Benzole und des Motor-Spiritus des Handels*, Dr. Karl Dieterich, *Auto-*

FIG. 1A ARRANGEMENT FOR TESTING AIR PERMEABILITY OF BUILDING MATERIALS

mobil-Rundschau, vol. 16, no. 9 10, p. 65, May 1915, 32 pp., p. 1.

RUNNING DIESEL ENGINES ON TAR OILS.

By cutting off the supplies of Galician oils, the war forced the Austrian engineers to turn their attention to other sources of fuel for running Diesel engines. The most natural were various forms of tars and tar oils with which considerable experience has been gained elsewhere previous to the war. The present article discusses the character of these new fuels, their methods of use (with some practical advices), and design of Diesel engines for heavy oils. Some test data are given. (*Dieselmotoren mit Teerölbetrieb*, Hans Schmidt, *Elektrotechnik und Maschinenbau*, vol. 33, no. 23, p. 277, June 6, 1915, 6 pp., p).

Materials of Construction

AIR PERMEABILITY OF BUILDING MATERIALS.

This paper presents data on air permeability of various building materials.

Investigations on the same subject have been previously carried out by C. Lang (in 1877) and by W. Gosebruch (in 1897). The present investigation was carried out in the laboratory of technical physics of the Technical High School at Munich, and was prompted by the necessity of determining the air permeability of materials which have been brought out on the market in recent years, for example, chalky sandstones.

The permeability was determined by means of the experimental arrangement shown in Fig. 1A. The stone *St* was placed in a funnel shaped sheet iron container *B* and packed, air tight, on the sides with a mixture of plastilin and putty made of wax and colophonium. The stone, on one side, is exposed to atmospheric air and on the other side to a gage pressure of about 100 mm of water produced by an air supply from the steel flask *S* containing air under a pressure of 150 atmospheres and equipped with the reducing valve *V*, by means of which the air can be taken for any length of time at any pressure desired. From the valve, the air passes through an air meter *U* and a drying flask *T*, to the funnel *B*. The drying flask contains calcium chloride by means of which the moisture is, as far as possible, kept away from the stone *St*. Between *T* and *B* there is a three-way cock *D*, by means of which the air meter *U* may be calibrated without dismantling the experimental arrangement (the method of calibration of the meter is described in detail). Directly in front of the material investigated are located, through cock

FIG. 1B CURVES SHOWING COEFFICIENT OF PERMEABILITY FOR BUILDING MATERIALS

stoppers, a water manometer *M* and thermometer *Th*. The readings of these instruments enable one to reduce the volume of air flowing through to the normal conditions of 760 mm mercury pressure and 0 deg. cent. temperature.

The material investigated was of various thicknesses, on the average 60 mm. The part of the stone facing the outside atmosphere had often to be limited to 10 x 10 cm, because with a larger area of outflow the air velocities in the meter and drying flask were too high, which created undesirable disturbances, such as carrying over of particles of calcium chloride into the piping. The duration of test was, on the average, 30 min., and air temperature about 20 deg. cent.

Each test was, as a rule, repeated three times and the data reported represent an average of all the three tests. The Lang law was sometimes used in calculations; viz., that the volume of air flowing through is inversely proportional to the thickness of the material. The values obtained are shown in the second column of Table 1. From them is calculated

the coefficient of permeability c , under the assumption that the volume of air Q flowing in a unit of time through an area F of stone is inversely proportional to its thickness d , and directly proportional to the gage pressure p . Under this assumption the volume of air flowing through the stone is defined by the equation

$$Q = c p F$$

and c indicates therefore the volume which will flow per hour through 1 sq. m. of stone surface, 1 m. thick, at a gage pressure of 1 mm. of water (Table 1, because of lack of space, is given in an abbreviated form). The "perforated stones" were bricks having four cylindrical perforations of 4 cm. in diameter, running parallel to their long edge, 12 cm. long. In addition to tests at the constant gage pressure of 100 mm, a series of tests were also made at variable pressures, data of which are given in the original article in

TABLE 1 DATA OF TESTS ON AIR PERMEABILITY OF BUILDING MATERIALS

Material	$Q - 1$ per hr.	c (Average value)
Sandstone	5,680,000	
	3,715,500	
	3,136,500	997
Chalky sandstone	76,060	
	39,170

Hand made brick (hard burned)	7,540	2 26
Machine made brick	8,346	
	6,820	
	1,915	
	1 880	1 42

a table. From these data, the coefficient of air permeability c was calculated and is shown in the curves of Fig. B. As has already been noticed by Gosebruch, c is not constant but increases as the pressure decreases, this increase being materially greater with goods of porous material than with tougher materials. The decrease of air permeability with an increase of the pressure differences is to be explained by the fact that the rapid growth of frictional resistance at greater pressure differences, and hence increased velocity of flow, produces a strong reduction of the motion of air through the material in the case of materials with very large pores. There is, in addition to that, the influence of flow produced by the phenomenon of expansion and turbulent motion in the hollows which affects still more the air permeability of the material at higher pressures. (*Die Luftdurchlässigkeit von Baumaterialien*, Hans Freiherr von Thielmann, *Gesundheits-Ingenieur*, vol. 38, no. 23, p. 265, June 5, 1915, 3pp., 3 figs. e .)

Mechanics

THEORY OF RESISTANCE TO ROLLING OF A HARD BODY OVER A PLASTIC SURFACE

The present investigation has been made in connection with the design of the first tractor constructed in Russia.

When the tractor was first built, it was found that losses

due to pure rolling constituted 40 per cent of the useful output of the engine, which of course made the tractor very inefficient. Certain alterations of design reduced these losses to 25 per cent, which showed the importance of accurately understanding the phenomenon of rolling resistance. The present investigation has in view only rolling resistance of such bodies as wheels of wagons, tractors, and chains used on caterpillar tractors. In addition to that are investigated the driven wheels of modern heavy field artillery pieces, equipped with flat band shoes of the Bonagente type.

The general property of the surface of rolling of such bodies is that one can entirely neglect both the elastic and permanent deformation in their surfaces of rolling as compared with the deformation of the roadways of rolling (such as have been considered in the present case). These limitations exclude the use of rubber automobile tires and other elastic tires. Further, the investigation is limited to the case of rolling where the resistance to rolling is sufficiently large; that means types of ground, and such loads, which permit of neglecting the elastic deformation of the roadway as compared with its permanent deformation.

Finally, in order to derive general laws of rolling resistance, it is necessary to know the law of resistance of the ground to crushing under the conditions of crushing which occur in rolling. The author derives the following formula for expressing the specific resistance f in kg per sq. cm of the ground to crushing

$$f = f_0 y \dots \dots \dots [1]$$

where f_0 (in kg per cu. cm) is the coefficient of specific resistance of the ground to crushing, i. e., the load in kg per 1 sq. cm of surface of ground, which causes permanent deformation of the ground to a depth of 1 cm. This formula shows that the specific resistance of the ground to crushing is proportional to the depth of the permanent deformation or crushing which corresponds to it.

As regards the resistance to rolling proper, Appell considers that pure resistance to rolling represents a couple opposing the rolling; the axis of this couple is parallel to the line of contact between the rolling body and ground, and may be located along the latter. The author considers only the case when the rolling body moves uniformly forward along a horizontal surface. The resistance to rolling R , he measures by the work of rolling L_R referred to a unit of length of path l travelled through by the body. In such a definition, the resistance to rolling is thought of as a certain imaginary force applied at all points of the rolling body, which has its axis of rotation traveling through paths identical with that of the entire body. The work of rolling in the general case is that work of the rolling body which is done by the surface forces acting between the surfaces of the rolling body and the ground (while the work of rolling necessarily includes that of sliding, the latter is here neglected). If the rolling body is assumed to be hard, no work is spent on the deformation of its surface since none is supposed to take place. In the case of rolling a hard body over plastic ground, the entire work of rolling represents the work of crushing of the ground, its slip and friction of the surface of rolling against the ground. The work of internal resistance, such as friction in the journals, and the work of gravity on inclines, are not included in the work of rolling. The essential feature in the dynamic method applied by the author to the determination of resistance to rolling is the

calculation of the work of deformation of the ground, the latter being determined from the conditions of equilibrium of the body, i. e., equilibrium of load applied to it, tractive effort and resistances of the ground.

From this, the author proceeds to the investigation of resistance to rolling on soft ground of the endless chain of a caterpillar (the tests were made on an American tractor made by the Holt Caterpillar Tractor Company). In the first part of the investigation it is assumed that the chain is smooth; that is, without protuberances which grip against the ground. The width of the chain is B cm and the length, L cm. The load Q kg is assumed to be distributed uniformly over all of the bearing surface, the specific pressure of this surface against the ground being represented by $q = \frac{Q}{BL}$.

In that case, in the ground a deformation will occur to the depth y_0 , at which the specific resistance of the ground f in kg per sq. cm will balance the specific resistance of the bearing surface $q = f$, wherein $f = f_0 y_0$.

It was found, by the way, that if the average value of f_0 of specific resistance of the ground be known, the depth of crushing of ground by the caterpillar of the tractor can be found from the following expressions:

$$y_0 = \frac{Q}{f_0 B L} ; f_0 = \frac{Q}{y_0 B L} ; Q = f_0 y_0 B L \dots \dots \dots [2]$$

In order to calculate the work of compression of the ground to the depth y_0 cm, the coefficient f_0 is assumed to be the same as above, which means that the work of slip of ground and the work of gliding of the chain over the ground is neglected, which can be done because these losses are actually practically negligible. The specific resistance of the ground f , which is overcome over an elementary section of the ground dy , will cause an expenditure of work $f dy$ and over the whole path y_0 , the compression of the ground $l_0 =$

$\int_0^{y_0} F \cdot dy = \int_0^{y_0} F_0 \cdot y_0 dy = F_0 \frac{y_0^2}{2}$ which is (in kg per cm) the specific work of deformation, on the assumption that the specific pressures and depths of deformation are proportional to each other. Let the specific resistance of the chain to rolling be equal to R kg, and the tractor travel an arbitrary distance of s cm. The work done by the resistance R will then be Rs kg per cm and this work of rolling is the work of deformation of the ground. But if the tractor travel through a distance s cm, the deformation made by the chain over this distance will represent a groove of area Bs and depth y_0 cm. The specific work of deformation to depth y_0 is $F_0 \frac{y_0^2}{2}$ and hence the total work of deformation over an area Bs will be

$$Bs F_0 \frac{y_0^2}{2} = Rs, \text{ hence} \\ R = \frac{F_0 y_0^2}{2} \cdot B \dots \dots \dots [3]$$

From this the author proceeds to the investigation of resistance to rolling of wheels of heavy artillery pieces equipped with flat band shoes of the Bonagente type. He goes through the calculation very carefully, and, among other things, compares the resistance to rolling of a Bonagente band with resistance to rolling of a cylindrical wheel of the same diameter and width of rim. He determines the formula and finds that while, with the Bonagente band, the expenditure of energy for the motion of the heavier gun is

3.14 h.p., the same gun, when moved on wide cylindrical wheels, will require 19.3 effective h.p., which shows that the introduction of flat movable supporting elements on the surface of rolling axles of all kinds of conveyances decreases the resistance to rolling of this surface many times. Among other things, he shows that in a chain (caterpillar type) rolling along a certain roadway, the coefficient of resistance to rolling increases in proportion to the load, while the resistance to rolling of the chain increases in proportion to the square of the load; hence, it is very inadvisable to overload the chain. With the same specific load per unit of over-all supporting surface of the chain, the resistance to rolling and the coefficient of the resistance to rolling of the body is greater the wider the chain and smaller the narrower the chain, but a long narrow chain is more advantageous than a wide, short one. In this connection, the author points out an interesting similarity between the caterpillar chain on one hand and a ski or skate on the other hand. Experience has shown that the latter two must be long and narrow in order to reduce the resistance to minimum. In general, whenever the friction of gliding goes together with crushing, destruction, or wearing of the roadway, it will depend not only on specific pressure of the body against the roadway, but also on the width of the body normal to the direction of motion. (*Teoriya soprotivleniya katanya tverdaya tyela po plasticheskamoo pooti*, B. B. Schultz, *Proceedings of the Imperial Russian Technical Society* (in Russian), vol. 49, no. 3, p. 81, March 1915, article not finished. *et al.*).

Refrigeration

AUTOMATICALLY OPERATING REFRIGERATING APPARATUS "AUTOFRIGOR"

The article describes refrigerating devices and installations of the Swiss Federal Exposition in Bern 1914. The part abstracted here refers to an automatic cooling apparatus for household use, called "Autofrigor," built by Esher Wyss & Co., Zurich, Switzerland.

The apparatus consists essentially of a reciprocating compressor built in, together with the condenser, in the casing K and driven by a vertical shaft from the electric motor M . Below the casing is located a ribbed evaporator R , the whole having therefore the shape of a vertical cylinder and taking up very little room. Methyl chloride is used as a cooling medium. Many of the details of design are of interest. The cylinder of the compressor z , has an oscillating motion. It is supported by transversal pins and presses upward by a spring against the slide face provided with suction slots forming the path by which the gas penetrates from the suction chamber a into the double acting cylinder, and then, by the pressure valve v , into the lower pressure space b . The ascending pipe r_1 conducts the gas to the upper pressure chamber c and pipe r_2 to the condenser e . The latter has an annular shape and is equipped with ribs running screw-wise, this being done in order to force the cooling medium to describe a longer path. The liquid which condenses because of the inclined position of the ribs, sticks in the neighborhood of the cold outer wall. The condenser is surrounded by a jacket m , through which cooling water flows in countercurrent. This external annular chamber is also provided with ribs in order to increase the water velocity. When it is necessary to clean the cooling surfaces, the jacket m can be easily taken off without opening the engine itself.

The cooling liquid condensing in the condenser collects at the bottom of the chamber *c* and then flows through the reducing nozzle *d*, where the pressure and temperature are reduced to the lowest stage possible in the evaporator. Instead of the regulating valve necessary with the ordinary ice machine, here an expansion nozzle is used. The evaporator *R*, provided with ribs, takes up heat from outside and is protected by a sheet iron jacket in order to prevent the cooling liquid near the walls from being affected by the heat of the evaporator.

The construction of the driving motor *M* is also peculiar.

FIG. 2. AUTOMATIC REFRIGERATING APPARATUS "AUTOREGULO"

Its rotor *t* is enclosed by a rigidly fixed armature and separated from it by a steel liner *f*. In order to have the eddy loss low, this liner is made of a special steel. In this way the pressure chambers *b* and *c* are separated from the outside atmosphere, air tight, without the use of any stuffing box. *f* has therefore to stand the gas pressure at the upper temperature stage which, in accordance with the temperature of the cooling water, may vary from 1.6 to 6 atmospheres. Tests made with this liner have, however, shown that permanent deformation occurs only at pressures from 80 to 100 atmospheres.

The lubrication of all movable parts has been provided for with particular care. Glycerine, which is used for this purpose, is placed in the upper pressure chamber *c*, and from there reaches all the lubricated parts of the compressor,—the piston, crank and shaft ends. It then collects in the lower

pressure chamber *b*, and is carried over again into the chamber *c* by the cooling medium, through the pipe *r*. The pipes *r* and *r* open therefore into the chamber *c* in such a manner that the lubricant would never, not even with the apparatus in a horizontal position, overflow and run from the apparatus. A small part of the glycerine is atomized and carried off by the cooling medium to the condenser chamber *c* and by nozzle *d* penetrates into the evaporator *R* where it collects at the bottom. When the machine is stopped, the pressure between *c*, *e* and *R* rapidly equalizes through the open nozzle *d*, while the small evaporator pressure in the container *g* under *R* is still maintained. There, however, the lubricant meets with the cooling medium, and is forced into the container *g* through the hole *h* and isolating valve *k*.

The article describes further a carbon dioxide compressor and an ammonia compressor; also a double acting compressor for sulphurous acid and the Audiffren-Singrim refrigerating machine. (*Die Kälte-Anlagen an der Schweiz. Landesausstellung Bern 1911*, Professor P. Ostertag, *Schweizerische Bauzeitung*, vol. 65, no. 26, p. 289, June 26, 1915, 4 pp., 10 figs., *d*).

Steam Engineering

PIKAL SYSTEM OF BOILER TUBE REPLACEMENT.

The article describes the so-called Pikal method of tube bending used both in fire tube and water tube boilers. It is well known that whenever a tube in a boiler has to be replaced a new tube must be used, as the processes now in use do not admit of securely welding on an old tube. Further, all processes of welding in tubes have the added disadvantage of reducing the inner diameter of the tubing, because of the overlapping at the place of welding. The Pikal method is claimed to permit of the use of old tubes without that disadvantage because as shown in Fig. 3, the use of a soft iron bending insert permits not only of the use of the old tubes but of their improvement in such a manner that they become even better than ordinary new tubes without the soft iron bending insert.

The main value of the use of the reinforced soft iron bending element lies in the fact that it is made of soft material, contrary to the usual practice, softer than the walls of the boiler tube. As a matter of fact, when hard boiler tubing is bended into the tube wall, and the tube has a higher strength than the tube wall (50 kg. per sq.m. as against 40 kg.), the limits of expansion of the two materials are in the same ratio. As a result, the limit of elongation of the tube wall is reached earlier than that of the tube itself. Iron which has reached its limit of elongation through continued expansion is no longer elastic and tends to maintain its expanded dimensions; hence the extended bore of the tube wall retains its expansion (compare 2 in Fig. 0), while the tube which is still elastic does come back to its original diameter. As a result, the tube and tube wall bore get out of touch and the tube does not sit steam-tight in the bore. A further bending is therefore necessary until the tube reaches its limit of expansion and in the end one has a contact between two materials, both of which are stressed beyond their limit of elasticity; which is neither permanent nor reliable.

In the Pikal process an entirely different situation is said to exist. The bending insert (tube) has a lower strength than the tube wall and therefore is the first to exceed its limit of elasticity. As a result, the tube wall even after a

comparatively long heading does not reach it at all if the process has been applied properly, and therefore remains elastic and encloses the no longer elastic end of the tube, thus creating a steam-tight and permanent contact.

Tests on the permanence of the Pikal method of locating the tube ends in the tube wall have been made at the laboratory of technical mechanics, at the Technical High School in Vienna and are said to have shown that the Pikal tube end sits tighter in the tube wall than an ordinary boiler tube. The tension in which the test piece came out from the tube wall was, with ordinary fire or water tubes, on the average 6310 kg. (13882 lb.) and with the Pikal attachments, 8320 kg. (18204 lb.). The Pikal process is especially applicable to old boilers. (*Das Pikalsche Rohrwechsel-Verfahren und seine praktische Anwendung, Der praktische Maschinen-Konstrukteur*, vol. 48, no. 23 '24, p. 105 (General Section), June 17, 1915, 3 pp., 2 figs. *de*).

CALCULATION OF DIMENSIONS OF SAFETY VALVES WITH HIGH LIFT.

Discussion of methods of calculation of safety valves with high lifts. Criticism of the Cario formula and experimental proof that this formula does not give sufficiently large values in the case of high efficiency boilers.

According to German police regulations for land boilers (Section 2, paragraph 9, December 17, 1908)—"Safety valves must carry such maximum load that when the pressure stipulated for a given boiler has been reached, all steam in excess of that should be able to escape. The cross-section of the safety valves must, under normal conditions of operation, be such as to be able to allow of the escape of enough steam so that the stipulated pressure should not be exceeded by more than one tenth its amount." According to the same regulations, the cross-section of the safety valves is sufficient if determined by the following formula:

$$F = 15 H \sqrt{\frac{1000}{p \gamma}}$$

where F is the cross-section of the valve in sq. mm H the heating area of the boiler in square meters p the gage pressure of steam in kg. per sq. cm.; γ the weight of 1 cm. of steam at gage pressure p in kg. In the case of a high lift valve of which the lift is at least $\frac{d}{4}$ (where d is the diameter of the valve), instead of the coefficient 15 in the above

formula, a coefficient 5 may be used, but in this case the manufacturer of the valve must guarantee that the lift indicated will be available in the case of a pressure exceeding a stipulated steam pressure by one tenth. The above formula is derived from the general formula

$$F = d h = \frac{D}{5} \frac{1}{2} \sqrt{\frac{1}{p \gamma}}$$

where h is the lift of the valve in mm; D the amount in kg. of steam generated per square meter of heating surface per hour; α coefficient of outflow of steam. The disadvantage of the above formula is that it does not seem to take into consideration the rate of output of steam in the boiler. It does not appear reasonable to provide safety valves of the same dimensions on the combined fire tube-smoke tube boiler, and the high efficiency boiler having an output of steam three or four times per unit of heating surface as large as the former. As a matter of fact the following case shows that when the load on the heating surface of the boiler is more than 30 kg. per sq. m. per hour, high lift safety valves cal-

culated in accordance with the above formula do not afford sufficient protection against excessive overloads.

In the power plant of the Rhine-Westphalian Electric Co. there was installed a high efficiency boiler having a heating area of 973 sq. m. and a grate area of 36.8 sq. m. It was provided with four high lift safety valves of 70 mm diameter, each sufficient to take care of excessive pressures in accordance with the above quoted police regulations. For experimental purposes, the steam outflow on the boiler was suddenly closed by an automatically operated rapid closing valve so that the entire amount of steam generated had to be let out by the safety valves. Although the latter were going full blast, the steam pressure rose to 17 atmospheres (safety limit 15.4 atmospheres) and would probably have gone up still further had not the fire been put out. In this case, therefore, even though the safety valves had been dimensioned in accordance with the police requirements, they could not prevent an excessive rise of pressure, and instead of four, six such valves had to be installed. While as a matter of fact such a situation was experimentally allowed to take place here, would not usually be met with under ordinary conditions, as it would be only under very exceptional

FIG. 3. PIKAL SYSTEM OF BOILER TUBE REPLACEMENT

circumstances that the entire output of steam would be cut off and the valves would have to take care of the steam generated, still it shows that safety valves dimensioned in accordance with the above formula are not sufficient to take care of the output in any high efficiency boilers. The author proposes, therefore, instead of the above formula, the following two formulae:

$$F_n = \frac{Q_{\max}}{2} \sqrt{\frac{1000}{p \gamma}} \text{ for ordinary safety valves}$$

$$F_n = \frac{Q_{\max}}{6} \sqrt{\frac{1000}{p \gamma}} \text{ for safety valves with high lift}$$

where Q_{\max} is the maximum steam output of the boiler per hour (in kg.). In this formula the heating area of the boiler is not taken into account at all, which is reasonable because it has no uniform influence on the amount of steam generated. (*Beitrag zur Berechnung von Hochdruck-Sicherheitsventilen*, *Orte, Zeits. für Dampfessel- und Maschinenbetrieb*, vol. 38, no. 22, p. 183, May 28, 1915, 2 pp. *tpc*.)

CALCULATION OF THE Laval NOZZLE BY THE PV DIAGRAM.

The adiabatic variation of state is given by the equation:

$$P V^k = \text{Const.} \dots \dots \dots [1]$$

If we denote

$$\lambda = \frac{k}{k-1} P V^{\frac{k-1}{k}} \dots \dots \dots [2]$$

it follows that

$$\lambda P^{1/k} V^{1/k} = \text{Constant} \dots \dots \dots [3]$$

λ is really the heat content of the medium at the state P, V .

The constant which is missing on the right side, can be neglected since, as we are going to show later, it is not the absolute values of λ , but the difference between these values that is of determining importance.

In Fig. 4 is plotted the curve $PI^* = \text{Const.}$; for saturated steam $k = 1.135$, for an initial pressure of 10 atmospheres absolute. To do this, the Brauer method was used, with $\tan \alpha = 0.2$, and $\tan \beta = 0.23$. The curve determined from equation [3] can also be plotted by the Brauer method with a slight alteration necessary for conveniently plotting the curve. The alteration consists in that, instead of 45 deg.,

of the right angles lie on the straight line ab , then it follows (Fig. 4) that

$$\frac{e}{e_1} \frac{b}{b_1} = \sqrt{\frac{c}{c_1} \frac{b}{b_1}} \text{ or } \sqrt{\frac{\lambda}{\lambda_1}} = \frac{c}{c_1}$$

that is, the velocities can be measured off on the line ab . If now the specific volumes ef corresponding to these points be plotted from b upwards on the axis of ordinates, a point m selected on the line ab , and from m a line equal to ml be drawn parallel to ck , then $bl = hj$ is the required cross-section. In this way can be determined the single points, and the curve fp plotted.

To determine the scale, values must be calculated for some definite point or state. The points d and m should be selected so that no sharp intersections of the lines should occur: a little practice will enable one to do this easily. (*Berechnung einer Lavatschen Düse mit Hilfe der pv-Diagramme*, Arthur Balog, *Zeits. für das gesamte Turbinenwesen*, vol. 12, no. 16, p. 181, June 10, 1915, 2 pp., 1 fig. mp.)

Varia
NEW METHOD OF PRODUCING PURE COMPRESSED HYDROGEN.

Until recently, hydrogen was a by-product of secondary importance, mainly burned in various ways. Of late, however, several chemical processes, such as the production of synthetic ammonia, and the use of hydrogen in autogenous welding, have created a big demand for it, by no means satisfied by the existing methods of production. The present method utilizes the decomposition of water under pressure, by iron.

Experiments in physical chemistry have shown that some elements, apparently inert, enter into various reactions under different conditions of temperature and pressure, and that the apparent inertness is really due to the low velocity of reaction, so that by changing the conditions of reaction, it becomes possible, for example, to unite apparently inert nitrogen with various elements, to introduce by means of catalysis hydrogen into unsaturated organic combinations, and finally to unite these two inert gases into synthetic ammonia. Coming more nearly to the production of hydrogen, in existing processes steam is decomposed by acting on hot iron. If, however, the reaction occurs at a low temperature, it becomes too slow. The effort of the inventor in the present instance has been to obtain the decomposition of water at as low a temperature as possible, so as to avoid contamination of hydrogen by carbon monoxide, which would make it useless for certain chemical processes; at the same time it was desired to carry on the reaction at a high speed so as to make its commercial application possible. To do this, water could not be used in the form of steam because, under 400 deg. cent., the velocity of reaction of steam with either carbon or metals is too low. Hence a new principle was applied and water was decomposed whilst in a liquid state at temperatures lying between its boiling point and 400 deg. cent. As the decomposition was carried on by means of carbon, what was practically obtained was burning carbon under flowing water. The reaction occurred in accordance with the formula

which shows that hydrogen and carbon dioxide were obtained in the correct stoichiometric ratio. In its simplest form, the reaction, however, goes on very slowly. But other observa-

FIG. 4. DIAGRAM SHOWING METHOD OF CALCULATION OF LAVAL NOZZLES

for the axis of ordinates 30 deg., and for the axis of abscissae 60 deg. are taken, whence the equation

$$1 + \tan 30^\circ \tan \beta_1 = (1 + \tan 60^\circ \tan \alpha_1)^{k-1} \dots [4]$$

is obtained. If we select $\beta_1 = 10$ deg., then $\alpha_1 = 31$ deg.

In this way the curve λV can be rapidly plotted (a further simplification may be introduced, by making $\beta = \beta_1$, or $\alpha = \alpha_1$).

The steam and gas velocity is determined from

$$c = \alpha \sqrt{\lambda_2 - \lambda_1} \dots [5]$$

The cross-section of the nozzle

$$c = \frac{1}{f} \dots [6]$$

From f the cross-section can be easily determined, and e. g. for a circular orifice

$$d = \beta \sqrt{f} \dots [7]$$

The calculations of [5], [6] and [7] can be very easily carried out graphically. If we select on the axis of ordinates a point b corresponding to the origin of the λV curve, and then select on the same axis a second point d , and, starting from d , draw rectangular triangles of which the apexes

tions have shown that the reaction between water and metals, especially iron, is very highly affected by the temperature, which the author explains by the fact that within the region of temperatures used, the water is already nearly split into two ions, H and OH. The H ion helps the iron to pass into solution and the comparatively high concentration of OH then produces an immediate settlement of the iron ions in the form of an insoluble oxyduloxide. The hydrogen ions are then liberated as free hydrogen. This reaction is materially speeded by the presence of some electrolyte in the water or by contact of the reacting substances with some noble metal.

Experiments on small vessels have shown that by the application of this process, it is easy to have hydrogen continually discharged from the vessel under high pressure without permitting the water of reaction to come out from the vessel in the form of steam. The apparatus used for tests on

FIG. 5. BERGIUS ARRANGEMENT FOR THE GENERATION OF HYDROGEN

a small scale is diagrammatically shown in Fig. 5. The vessel in which the reaction occurs is provided with a conical stopper, a narrow pipe serving as a return cooler. To this pipe is connected a second small vessel, the purpose of which is to catch water drops carried over by the gas mechanically while other piping leads to a high pressure container in which the hydrogen developed under high pressure is kept stored up. The experimental apparatus was filled with iron powder, water and some electrolyte and then heated up. Hydrogen was developed under a working pressure of 300 atmospheres, which happens to be a convenient pressure for use in various chemical processes where there is a demand for this gas.

The entire process requires only coal and water and compressed hydrogen is obtained without the utilization of special compressing plant. The hydrogen is stated to be purer than any other kind directly obtainable. (*Eine neue Methode zur Herstellung reinen komprimierten Wasserstoffs*, Dr. Fr. HEAT TRANSMISSION AND TUBE LENGTH IN MARINE FEED-WATER HEATERS.

Investigation of the theory of heat transmission in feed water heaters and the elements affecting it. Reports of tests on Bureau of Steam Engineering heaters and Koerting film heaters.

Heat resistance is best measured in terms of its reciprocal, K , thermal conductivity, the number of heat units transmitted per unit of area across a given space per unit of time. Denoting by Q heat transferred per hour in B.t.u., t_m mean temperature difference, S area of heating surface in square feet, and K rate of heat transmission in B.t.u. per hour per square foot per degree of temperature difference, we have

$$Q = S K t_m$$

As regards the nature of K , it must be borne in mind that the total thermal resistance is dependent upon two film resistance, scale, and metal wall resistance.

Proper preparation of the tube material and proper up-keep and operation will eliminate the scale condition. There are quite comprehensive data on the magnitude of metal wall resistance, which show that the temperature difference on the two sides of the metal tube is very small. Tube material or tube thickness only slightly impedes heat flow and a water film 0.00173 in. thick will give the same resistance as a 1-in. thickness of copper tube. It is evident, therefore, that a metal tube will transmit all the heat that is presented to its surface and the controlling resistances lie in the two films which cling to the

metal surfaces, the resistance on both sides being much alike because the condensing steam presents a wet surface. The formation of such a film on the water side is a friction effect, the microscopic irregularities of the surface of the metal walls preventing the particles of water from being swept along with the major current. Hence the problem in producing high transmission in heaters is the destruction of this water film by a scrubbing action which may be produced by a high velocity along the heating surface, and after the limit of heat transmission has been reached on the water side by a velocity within practical limits, the controlling resistance passes to the steam side, so that the only way to further increase heat transmission is to sweep away the film on the steam side.

A factor in the heat transfer equation of equal importance with the coefficient of conductivity is temperature difference. It can be increased in but one way; by raising the temperature of the heating medium. Further, it is found that the increase in exhaust temperature obtained by throttling the auxiliary exhaust is also of some value.

The author then discusses types of temperature gradients resulting from various assumptions as to the functional dependence of heat transfer—for example, when a transfer is at any instant proportional to the temperature difference. He gives an analysis for this case and the curve obtained when inlet and outlet temperatures for a given steam pressure and water velocity are known. He shows, however, that

FIG. 6A. TEMPERATURE GRADIENT IN A $\frac{3}{4}$ IN. COPPER TUBE.

the analysis given would be very satisfactory were it not for the fact that there exists considerable experimental evidence that heat transfer in feed heaters is not directly proportional to temperature difference, and he proves it by results obtained from a single tube experimental heater tested under his own direction at the Engineering Experimental Station.

This heater consisted of a single $\frac{3}{4}$ in. copper tube, No. 18 B. W. G., 4 ft. long, secured within a 4 in. pipe which forms the steam space. The inlet could be regulated to any desired temperature by an auxiliary heater and the temperature gradients of any given water rate are determined by noting the inlet and outlet temperature at 3 min. intervals for a period of 18 min. In this way, in a heater the length of which could be varied to suit temporary conditions of velocity, the temperature could be determined at 4 ft. intervals. Table 2 gives data from a typical set of tests with the steam pressure of 5 lb. gage and the water velocity of about 4 ft. per sec.

The gradient corresponding to columns 2, 3 and 4 is plotted in Fig. 6A. Although the temperature rise per pass varies from 15.4 to 37.8, the average arithmetical temperature difference may be very closely considered to be the mean temperature difference per pass, since the curvature of the temperature gradient is very slight and the straight line connecting any two points varies only slightly from the best smooth curve through the points.

The relation between temperature difference and heat

transfer per hour, columns 5 and 7 of Table 2, is plotted on logarithmic cross-section paper (Fig. 6C) and these points fall quite accurately on a straight line, which is equivalent to saying that heat transfer in feed water heaters is proportional to some power of the instantaneous temperature difference which may be expressed analytically as

$$Q = K S (t_s - t)^n$$

where n is the slope of the line on the logarithmic curve, in this case, a value somewhat less than unity.

From this the author derives the following formula

$$t_m = \frac{(1-n)(t_o - t_1)}{(t_s - t_1)^{1-n} - (t_s - t_o)^{1-n}}$$

which is the same as that derived by Mr. Orrok for condensers, but is obtained from the basic experimental proof that heat transfer is proportional to a power of the temperature difference instead of the secondary fact that the rate of heat transmission per degree of temperature difference is proportional to a power of temperature difference. This latter method is more involved, inasmuch as it introduces another variable factor U , which varies with temperature, and there is a decided disadvantage in obtaining U as function of t because the whole purpose is to obtain an experimental value of K which will remain constant throughout the heater design in question. A comparison of the two laws of temperature variation for the range of data in Table 2 is shown in the curves of Fig. 6B. The lines A , B and C are the gradi-

FIG. 6B. CURVES SHOWING A COMPARISON OF THE TWO LAWS OF TEMPERATURE VARIATION.

ents from the relation $l = c (t_s - t)^n$ where the values of n are 0.7, 0.8 and 0.9. The line D is the gradient from the relation $l = C \log_e (t_s - t)$ and the semicircles mark the inlet and outlet points in columns 2 and 3 of Table 2.

Tests of Heat Transmission in Marine Heaters. The above established general law for heat transfer was applied by the author to the test of heaters used in the naval service, two

types having been exhaustively investigated—namely, a feed heater designed by the Bureau of Steam Engineering for battleships 34 and 35, and incidentally used in evaporator plants on board ship; and a spiral corrugated film heater manufactured by Schutte & Koerting.

The Bureau feed water heater consists of a composition shell containing 117 semicircular $\frac{3}{4}$ in. tubes, No. 16 B. W. G. expanded into a composition tube sheet and a cast-steel bonnet, cast so as to form separate passages over the two ends of the tubes. When used for feed heating, the feed water passes through the tubes and the steam circulates in the

In some of the tests the tubes were fitted with retarders consisting of annealed copper strips $\frac{5}{8}$ in. wide and 0.0268 in. thick, twisted into a spiral of 6 in. pitch. The dropping pressure through each pass of the heater is measured by a differential mercury gage, 0.55 in. of mercury without retarders as against 0.98 with retarders, which shows that the introduction of the retarders involves no serious increase in friction. The author finds that, for the heater in question, the heat transfer-temperature relations is given by $Q = K (t_s - t)^n$ where Q = B.t.u. per hour per sq. ft. of heating surface; K = a constant from experiment; t_s = average saturation

FIG. 6C. HEAT TRANSFER-TEMPERATURE RELATION OF A $\frac{3}{4}$ IN. NO. 16 B. W. TUBE.

outer casing. The total heating surface is 88.2 sq. ft., of which 86 sq. ft. is tube area. The net area through the water passage of tubes is .362 sq. ft. The data on these tests are only very briefly reported here because they were published in full in the Journal of the American Society of Naval Engineers, February 1912, pp. 155-166.

The tests were divided into two main groups, dependent upon the inlet temperature maintained at about 80 deg. Fahr. in the first case and from 130 to 150 deg. in the second, with further subdivision, according to feed velocity and steam pressure. The mean water velocities chosen were 35, 71, 107, 143 and 171 ft. per minute. The steam pressures were 5, 10, 15 and 20 lb. gage and the water pressure was held at over 230 to 250 lb. gage. The tests show in general an increase of heat transfer with steam pressure and with velocity, but a decrease at the same pressure with increasing temperature difference. There were, however, irregularities in data which cast doubt on the results.

steam pressure within the heater; t = water temperature; n = a constant from experiment. Furthermore, n is the slope of the curve on the logarithmic plot and has for this heater a value $n = 0.85$, which is independent of the velocity and of the use of retarders. The value of K , however, which is the intersection of the line prolonged and the vertical axis when $(t_s - t) = 1$ is dependent on the velocity and is therefore the function which varies with the greater or less removal of the water side film. The use of retarders has the same effect as increasing the velocity by increasing the value of K .

From data derived by Clement and Garland and published in a bulletin entitled "Study of Heat Transmission" (University of Illinois Engineering Experiment Station, Bulletin No. 40), the author comes to the conclusion that in a feed heater, the controlling resistance lies on the water side and is subject to correction by a mechanical agitating or mixing device up to the point where water ceases to flow as a uni-

form fluid, the point known as the critical velocity of the fluid.

As regards the use of retarders, the present tests have shown that in the Bureau type of heater, the introduction of the spiral retarders increased, at the water rate of 1500 lb. per tube per hour, the heat transmission by 16 per cent; at 2000 lb., 7.5 per cent; at 2500 lb., 14.9 per cent, and at 3000 lb., 14.8 per cent.

Further tests were made on a Schutte & Koerting spirally corrugated film heater of the usual type. In this heater, the water flows through in a $\frac{5}{16}$ in. thick nominal film between two corrugated tubes, the steam circulating downward around the outer tube and within the inner tube. When the heater was put into service it was found that the least practical rate of discharge was 7500 lb. of water per hour, for at lower rates the outlet water was at such a high temperature that much of it was flashed into steam beyond the outlet control valve. As a result, the rates of discharge selected for this purpose were 7500, 10,000 and 15,000 lb. per hr.

The heat transmitted in B.t.u. per square foot per hour was found to reach a value of 147,922 lb. at the highest ve-

lue of n (exponent in the heat transfer relation) had to be determined indirectly. Since the temperature rise of test was usually in excess of 100 deg., the average temperature difference would not be close enough to the mean temperature to obtain the value of the exponent directly from the logarithmic plot.

It was found that only a slight advantage can be gained from water film agitation above 7500 lb. per tube per hour. This must be considered as the critical velocity for such construction and higher rates would produce no increased heat transfer, but would result in excessive friction losses. As regards the relation between the vertical and horizontal heaters of the same film thickness, at 500 lb. of water per unit of surface, the horizontal heater shows rates of heat transmission of 720 B.t.u. per hr. per degree of temperature difference as against 910 B.t.u. for the vertical heater, an advantage of 26.4 per cent, in favor of vertical installation. Care was taken to give the horizontal heater sufficient pitch to cause the water of condensation to flow freely from the tubes. This did not entirely accomplish the desired results, as the

locity, which corresponds to a heat transmission per square foot per hour per degree average temperature difference of 1,227 B.t.u., or more than double that obtained at equivalent velocities in the Bureau type of heater. However, the true velocity of water in this heater is not certain as the spiral corrugation will produce an agitation greater than direct flow through a uniform film of the same area. In every case the axial velocity was considered and the velocity corresponding to a reasonable friction loss would be about 250 ft. per minute, or 12,930 lb. of water per hr.

A small experimental heater of this type was tested at the Engineering Experimental Station in Annapolis in 1912. The experimental apparatus involved four pairs of spirally corrugated tubes arranged in two passes, the film thickness in the design finally adopted being approximately $\frac{3}{16}$ in. The heater was initially designed for horizontal installation, but a slight modification of the lower header permitted of vertical mounting. The article describes in detail the experimental apparatus and method of conducting the tests. No practical way was found to give an accurate temperature of the water at the reversal of flow in the lower head; hence

weights of condensed steam for the several intervals of any one test vary between wide limits, whereas in the vertical heater these quantities remain remarkably constant. The great difference between the performance of the horizontal and vertical heaters cannot, however, be entirely accounted for by the accumulation of water of condensation in the lower part of the corrugations of the inner tube, but the reason for the difference is to be found in the accumulation of air in the steam space, which cannot be eliminated by blowing through pet cocks in the covers. The presence of this air would actively reduce the transmitting surface, and this, taken with the irregular flow of water of condensation, would explain the variation. In a subsequent test, a more efficient disposal of air, attended, however, with a considerable loss of steam, resulted in rates of heat transmission of about 5 per cent less for the horizontal than for the vertical installation.

In the case of a $\frac{3}{16}$ in. film vertical heater there is a noticeable lack of uniformity between the friction losses for high and low rates of flow, while the $\frac{3}{16}$ in. film gives uniform values of friction loss under widely varied temperature limits, and possesses the further great advantage of the re-

placement of tubes without danger of change in adjustment sufficient to modify the nominal film thickness.

The author suggests, therefore, the standardization of the $\frac{3}{16}$ in. filta vertical heater as being advisable, besides the important consideration of minimum friction loss, also because of equal heat transfer per unit of heating surface, efficient removal of water of condensation and non-condensable gases from contact with the heating surface, and ability to maintain a uniform film thickness when assembling the units (55 pp., 20 figs. *et al.*).

SOME FALLACIES IN CEMENT TESTING

The paper discusses what the author refers to as fallacies in cement tests, or more precisely, various possible sources of error affecting the reliability of results obtained from such test. He starts with the stipulation of the British Standards Specification, that before any sample of cement is submitted to certain tests, "it shall be spread out for a depth of three inches for 24 hours in a temperature of from 58 to 64 deg. Fahr." One of the possible objects of this procedure was to obtain conditions similar to those governing cement which has lain in sacks or casks for two or three weeks. In order to test the effect on certain types of storage in sacks, the author tested three sets of samples from specimens dispatched to him at the time of the filling of the sacks, and found that in the majority of cases, the cement became quick in initial setting after storage in sacks for 14 and 28 days, with some exceptions. The final setting was in some cases slowed and in others quickened, but it is impossible to generalize on the results so that the only thing one can say is that cement kept in sacks, under ordinary conditions of dry storage, may either become slower or quicker setting, but the results cannot be foretold.

Tests were also made to determine the effect of aerating in layers three inches deep. It was found that the setting time, tested in accordance with the British Standards Specification, does not agree with that of the bulk sample which it is supposed to represent. There is no relation between the effects of aerating cement for 24 hours and storing in sacks for two weeks or a month; the setting time is differently affected when the same cement is aerated or stored in bulk in different localities or at different periods. Changes in setting time are not due to some inherent property of different cements. The erratic behavior found is common to all the samples tested, the composition of which vary with considerable limits. The retardation or acceleration of setting time on storage or aerating must be due, therefore, to chemical changes brought about by the absorption of some constitu-

ents present in the mixture. To test this, a quantity of slow-setting cement was placed in a large glass tube and a current of purified air, free from ammonia, carbonic anhydride and moisture passed over it continuously for 24 hours. It was found that pure dry air had no effect upon the setting time of the cement, the loss constituents remaining practically constant. On the other hand, the effect of moist air, free from carbonic anhydride, was distinctly marked, although the percentage of moisture absorbed was comparatively small. The acceleration of setting time by carbonic anhydride was also clearly proved.

The author discusses also the question of fineness of cement in tests, and the exactness of the mesh of the sieve. He finds that sieves which conform to the British Standards Specification often give, in testing, most erratic results. Further, the size of the sieve itself has been overlooked, which is important because the same weight of cement, sifted for the same period of time will be more effectively sifted over a large area than over a small one. (Proved by actual experiment.)

The specific gravity test still retained in the British Standards Specification, is considered to be a test for underburnt cement, but gives really no indication of the degree of calcination. The author's experience is that, when cement is taken freshly from the kiln, the specific gravity is practically the same whether the clinker be well burned or underburned, provided the carbonic anhydride has been all, or nearly all, expelled from the chalk. The author thinks, therefore, that the test should not be retained because, first, the direct method of estimating the loss on ignition is more accurate than a determination of specific gravity, and second, an artificial cement, especially if finely ground, exposed to air, but kept in a damp store for some time, may have its gravity reduced to a figure quite as low as that of many natural cements. The only certain guide by which to determine whether a sample is or is not a natural cement is a chemical analysis and with the data this gives, the specific gravity becomes superfluous.

Tensile or crushing tests of cement with standard sand do not represent, in the opinion of the author, the best results of which the cement is capable but give results which are standardized and therefore comparable with those obtained by different operators. The crushing strength, especially of concrete or mortar, depends largely upon the size and character of the aggregate, the absence or presence of dust and clay matter, and the density of the mass. Experiments made by the author have shown that the crushing resistance of concrete, made from the same cement, varies not only with the size but also with the character of the aggregate.

The author is distinctly against the use of the so-called autoclave test, and claims that to show the utility of such a test it must be shown, further, that the cement which passes the simplest soundness tests generally employed will yet be dangerous in ordinary work, and second, that the autoclave test will detect such cements with certainty, neither of which points have been demonstrated so far.

Finally, the author rejects the widely accepted theory that unsoundness of cement may be due to free lime locked up within the particles of the ground material. The improvement in soundness brought about by the exposure of cement to a damp atmosphere might lend some apparent support to the contention that the freed lime is thereby slaked and rendered harmless; but he fails to see how the small amount

of moisture absorbed from the air penetrates the particle and slakes the free lime when the enormously larger quantity of water used in gaging the cement fails to do it. Furthermore, unsound cement stored for some time in air-tight receptacles, in which presumably no slaking of free lime can occur, still becomes perfectly sound. Finally, it is a well known fact that low-lime cement is often more unsound than high-limed cement, which is again antagonistic to the free-lime theory. The author's view is that unsoundness in cement is probably due to the presence of an abnormal silicate perhaps dicalcium silicate, which is an unstable compound and slowly disintegrates with an increase in volume (18 pp., *g*).

TENTH ANNUAL CONFERENCE ON WEIGHTS AND MEASURES

AUTOMATIC SCALES, F. J. SCHILINK

The paper, read before the Tenth Annual Conference on Weights and Measures of the United States, May 26, 1915, is abstracted from an advance publication in *The Scale Journal*, (Vol. 1st, No. 9, June 25, 1915, Chicago, Illinois).

The author divides weighing scales into two classes; viz., scales in which the weight of the load is determined by the manipulation of suitable balancing or equilibrating means, through the agency of an operator, and those in which the weight is obtained by merely placing the load to be weighed upon the scale and reading the indication of some self-actuated mechanism. Automatic scales, which is the generic name of scales of the second class, may be of many forms, such as scales in which the reading is obtained directly through the agency of a variable equilibrating element dependent in its action upon the magnitude of the load being weighed; scales which perform repeated weighings of a definite amount of commodity which, though fixed for a single setting of the scale, may be adjusted within a certain range (package scales or dumping scales).

As a means for obtaining automatic indications may be used either an elastic body, the deformation of which bears some known relation to the external force applied to it, or a system of non-elastic bodies having a definite configuration for a given magnitude and direction of the forces which are applied to it. The first class is exemplified in spring scales of which the helical or screw spring scale is the most common. All forms of springs are, however, subject to certain changes which affect their utility as weighing elements; among these changes are, first, imperfect elasticity, which results in the slight differences in the elongation of the spring at a given load, depending upon whether the load is being increased or decreased, and also upon by what are called fatigue effects; the effects of imperfect elasticity can be reduced to a minimum by using the spring at a low working stress. Second, error due to change of elastic properties and dimensions of the spring with temperature. This may be corrected or avoided by one of several methods, such as automatically changing the ratio of the leverage as the temperature changes. Another method is to keep the spring at a constant and definite temperature, and finally, to use springs made of special alloy steels.

Pendulum scales, strictly speaking, include also the lever system of an ordinary beam scale. The author describes in detail the pendulum scale in its simplest form, and the cam pendulum scale. The following considerations have affected the design of such scales: if the reading chart of a pendulum scale is divided into intervals which are not uniform, any

change of level of the scale taking place in the plane of the pendulum will cause the pointer to start from a different point, and if the scale be rebalanced without being releveled, it will read inaccurately. If, on the other hand, the graduations are uniformly spaced, a slight shift of the level of the scale only changes the zero region of the pointer and an adjustment of the balance by the means provided for that purpose will cause the scale to read correctly. In practice, however, the frequent adjustment of the zero balance becomes troublesome and to avoid it, the double pendulum construction is used and a weighing scale practically free from changes of balance or weight indication from small shifts of level is obtained.

The third type of equilibrating element is the cam mechanism, which is an extension of the familiar wheel and axle principle. The author describes it in detail. The cam principle is frequently employed in connection with the pendulum system, and in many cases it is difficult to distinguish sharply between cam and pendulum scales.

Every pendulum scale in which the uniformity of graduation interval is secured by means of a cam and wrapping connector is an illustration of such a combination.

In a pendulum scale having a single pendulum there is generally no cam, or only one. In a cam scale there are two, one for connection to a counterpoise and one for connection to the platform levers or weight receiving system. To add the pendulum principle to such a cam system it is only necessary to establish the center of gravity of the cam outside the center of rotation. Then the applied weight of the load is resisted not only by the fixed weight of the counterpoise, but also by the weight of the cam body itself, acting also at a variable distance from the axis of rotation. There are, then, in action, two resisting forces, each obeying a different law, and to have equally-spaced graduation, the cam must be made of such contour as to suit the combination of these two effects. Practically, this means that in the construction of a scale which is intended to act upon the cam principle alone, there should be added a small weight, adjustable on an arm extending out from the cam body, so that, by shifting the arm and the weight upon it, the center of gravity of the cam body may be brought into the axis of rotation. Conversely, the center of gravity may be intentionally shifted outside the axis of rotation any suitable amount, in order to take advantage of the corrective effect which can thus be obtained.

From this, the author proceeds to the description of other parts of the automatic scale, such as the load receiving mechanism, i. e., the lever system, the indicating mechanism, and auxiliary devices, such as the damping and relieving mechanisms. The writer expressed a belief that, in the future, automatic scales will find a continually widening application in mercantile and industrial service, while modern methods of design and manufacture are sure to bring forth refinements in construction and extension of utility (6 pp., 7 figs., *dg*).

THE HARDENING OF METALS

A general discussion of the subject of the hardening of metals, at the Faraday Society, on November 23, 1914, in order to afford an opportunity for a further and fuller discussion of this important subject, somewhat briefly taken up at the last meeting of the Iron and Steel Institute.

Sir Robert Hadfield, in the chair, opened the discussion by a brief introduction in which, among other things, he spoke of a specimen of steel found in India, on good authority dating as far back as 125 B.C. Its interest lies in the fact that it is probably the first specimen of that age containing as much as seventy per cent carbon, which indicates that it can be readily hardened by heating and quenching in water. The material has been in its present condition for probably more than 2,000 years and now, after being heated and quenched, hardens exactly as if it had been made only yesterday, thus showing that notwithstanding this long interval and high surface oxidation, this specimen has undergone no secular change of structure or alteration in the well known capacity of an alloy of iron with carbon to harden under certain conditions.

Doctor G. T. Beilby read a paper on the hardening of metals, in which he indicated in a brief and general manner how hardening occurs and to what it is due.

Professor Ernst Cohen, of Utrecht, presented a paper on The Influence of Allotropy on the Metastability of Metals and Its Bearing on Chemistry, Physics and Technics. The paper reports an extensive and highly interesting investigation on electrolytic transformation of metals, in particular of bismuth, cadmium, copper, zinc, antimony, sodium, potassium and lead. The investigation as carried out involved the use of a pycnometer and dilatometer and of the electric potential method.

In previous experiments on bismuth, the writer found that metals may show very great retardation in undergoing molecular changes at temperatures either above or below their transition points. This reluctance to undergo change is probably one of the reasons why the phenomena observed by the writer have remained undiscovered until now. The experiments have shown that the same applies to cadmium; that cadmium is further able to undergo a reversible transformation; that apparently there may be several transition points at various temperatures and that it is very difficult, if not impossible, to fix the real transition point of the pure modifications. In order to prepare a sharply defined modification of cadmium, avoiding high temperatures, an extensive investigation of the electrolytic method, of considerable value in other directions, has been carried out. It is not reported here, however, because of lack of space.

As regards the phenomena observed in the investigations on cadmium, lead, bismuth, copper, zinc and antimony, the

author concludes that the pure metals as we have known them until now, are metastable specimens consisting of two or more allotropic forms, which is a consequence of the very strong retardation which accompanies the reversible change of these allotropic modifications below and above their transition points.

The existing data on the physical constants of metal, unknown until now, are thus considered as entirely fortuitous values depending upon the previous thermal history of the material used. The physical constants which refer to a well defined condition of the metal are so far unknown, and as the phenomena described by the author have been unknown up to the present, metallurgists have not been able to take them into account in studying the hardening of metal, and yet these reversible transformations which often go on very slowly in consequence of the retardations mentioned above, must play an important role when the metals are subjected to changes of temperature. This role may become fatal if the metals are in contact with electrolytes (water, for instance) as this accelerates enormously the transformation velocity.

In an appendix, the author discusses further the question of heats of transformation of metals and the specific heats of different metals at different temperatures. Although the metals used by the author were of high purity and *cast*, which would indicate that the condition of the material was definite, it was found that previous heat treatment must still be taken into account and the values for the specific heats of these metals must be considered as fortuitous. From experiments on sodium it was found that sodium can be either monotropic or enantiotropic (a fact which was not previously known), and that it is possible to obtain at least a nearly quantitative yield through this stable or metastable solid modification from a metallic grade.

J. C. W. Humfrey presented a paper on the subject of the amorphous phase in the hardening of steels, in which he offered an explanation of the hardening of steels, using as a basis data of recent experiments upon the reflection of X-rays from crystal surfaces. The theory of crystal structure, as now accepted, asserts that the regularity of crystal structure within a crystal is two-fold, viz.:

- a The centers of gravity of the molecules are arranged together according to one of a series of geometrical devices called "space lattices," in which each point in the lattice is surrounded by a similar distribution of other points.
- b In each molecule of a crystal, the atoms are similarly situated.

The author considers that it is the second form of regularity which essentially gives rise to the first; or in other words, that in crystallization from fusion, it is the forces exerted by each molecule upon its neighbors (i.e. forces due to the resultant reactions of its atoms), which bring about the space-lattice structure of the crystal. The allotropic change must be considered as being essentially accompanied by a change in the internal structure of the molecule; e.g., a reorganization of the atoms composing them or a change in their number. Before this reorganization can be completed, however, there must be at least a temporary state of disorder, and it is during this disorder that the author considers that the structure must be looked upon as amorphous, and the intermediate amorphous state may be realized as corresponding to the liquid which would be formed by the fusion of the solid phase, stable at the lower temperature.

if the conditions could be so adjusted that the subsequent recrystallization were avoided. In certain cases, such phenomena can be actually observed, e.g., in the case of sulphur the changing from the monoclinic to the rhombic and back again normally occurs at the temperature of 95.6 deg. cent. In the case of iron, the temperature-tenacity curves obtained by Rosenhain and the present writer give strong indications that a similar phenomenon might occur and that if on heating a sample of iron, suitable conditions of pressure would be applied which prevented recrystallization to the γ , then a true melting point would be observed in the neighborhood of 900 deg. cent. That a second crystalline phase may form after the first is broken down to amorphous necessitates the condition that the mass is not too viscous or that it forces the crystallization to overcome the viscosity and to marshal the molecules into their new orientation. Beilby proved that such a condition is not invariably present, since any amorphous phase formed by severe overstrain in the cold possesses a definite stability up to certain well-marked temperatures and only passes back into the crystalline state when these temperatures are exceeded. In a metal in which an allotropic change normally takes place at a temperature well above that at which the viscosity is sufficient to prevent crystallization, abnormal conditions, such as rapid cooling, may delay the change to well below this temperature.

From experimental data it was found that while in the case of pure iron there is a range of about 400 deg. cent. between the temperatures at which the breakdown of the γ iron occurs and that at which the recrystallization of the α iron becomes difficult, yet in the case of an 0.9 per cent. carbon steel, the range is reduced to less than 200 deg. cent. The probability of retaining by sudden cooling some of the amorphous phase formed by the breaking down of the γ structure is therefore much greater with increasing carbon contents. Another factor causes the presence of carbon to still further promote the retention. Above the changing point, the carbide is in solid solution in the austenite, and when this phase breaks down to amorphous, the carbide molecules will still remain closely intermingled with those of the α iron. But before the amorphous can recrystallize, the two different kinds of molecules have to segregate, since the carbide is not soluble in either α or β iron. Such segregation must necessarily be a slow process in an uncooled viscous mass and rapid cooling may easily allow the minimum temperature of crystallization to be passed before it has had time to take place.

SOCIETY OF ENGINEERS

Vol. 6, no. 5, May 1915, London.

SOME FUTURE DEVELOPMENTS IN HEATING AND VENTILATION, A. H. BARKER

A general discussion of the development of heating and ventilation with an exposition of the underlying difficulties in its way, and some suggestions as to the ways of overcoming them.

In the author's opinion the main difficulty in developing heating and ventilating engineering on a strictly scientific basis lies, first, in the great complexity of the problems with which one has to deal in every individual case, and next, in the fact that the object of both heating and ventilation, though primarily physiological, is also to some extent psychological. It is necessary to keep the inhabited rooms healthy, but of almost equal importance is the necessity of

keeping them comfortable. Some physiologists say that it is desirable, in the interest of health, that the temperature maintained shall be as low as a human being can endure without real discomfort, while others claim that the rooms should be so warm that the man feels comfortable without any effort. No one can tell, say within 300 per cent. how much fresh air per head per hour is the minimum consistent with health, and the matter becomes still more complicated because of the baffling fact that a man is comfortable when he thinks he is comfortable; if we can make him imagine he is comfortable, without the alteration of any single condition, we can make him feel comfortable.

The room filled with air which is perfectly pure, as far as chemical analysis can detect, may *feel* very stuffy; for instance, the House of Commons' air in the debating chamber is chemically speaking as pure as in any room in the world, yet it produces without any possible doubt the lassitude and sleepiness, infection, etc.,—effects which we are accustomed to think of as connected with defective ventilation. On the contrary, a room may feel fresh and sweet in which, judging by chemical standards, the air is far from pure. There must be some combination of chemical and physical conditions, which accounts for the effect so far as it is objective, but nobody up to the present time has ventured to specify what that combination is.

The future of the sciences of heating and ventilation depends on the analysis of the conditions which produce the feeling of comfort and other effects. The criterion of success is a pleasing effect on the feelings of an individual, but we must, in order to get this subject on a scientific basis, be able to translate the feelings of an individual into terms of measurable physical conditions. The physiologist and hygienist have to specify what are the conditions that will be regarded as healthy and comfortable, and the only legitimate function of the engineer as such is to produce and control such specified conditions; for instance in the matter of heating, the practical problem before the engineer is to introduce heat into a building in such quantity and such form as to make the people comfortable. This can be done *either* by convection currents *or* by radiation, a fact which has received, so far, no proper recognition. Indeed it does not seem even to be generally clearly understood just what is meant by the expression "temperature of the room." Commonly understood, it means the reading of an accurate thermometer suspended in the room, but a thermometer suspended in a room does not indicate the temperature of the room surrounding it, as it is largely influenced by the great amount of radiant energy impinging on the bulb which has no connection with air temperature.

In this connection, the author mentions the fact that a good many people cannot endure radiator heat. It is absurd to believe that it is a "dry" heat, as it is no more dry than any other form of heat. Why then is radiator heat so distasteful to many persons? To answer this question, the author has introduced a conception which he has named "radiant temperature," the idea of which is that temperature which a thermometer would register if there were no air in the room at all, a sort of mean of the temperature of the surrounding walls. There are four different quantities—air temperature, radiant temperature, quantity of convected heat and quantity of radiant energy, which must be measured before one can answer the questions which come up in connection with various types of heating, and before that is

done, it is necessary to determine experimentally what is the relation between the thermometer reading, the air temperature and the radiant temperature. The author has devised for this purpose, several instruments of comparatively simple construction. One of them has as its object to ascertain what are the mean temperatures of the surfaces of the walls of the room, the furniture, and of the exposed surfaces, the temperatures of which have an effect on the bulb of the thermometer. The second instrument is for finding the actual temperature of the air. In this apparatus the radiant temperature is artificially made identical with the air temperature so that both are the same as the temperature reading.

The author claims to have proved by the aid of these instruments that the stuffy feeling which is often associated with systems of central heating is due largely, but not entirely, to the fact that the air temperature is too high and the radiant temperature is too low; the freshness of a building depends on keeping the air temperature relatively low and the radiant temperature high. It is the temperature and humidity of the air, which are the important points, and not its chemical freedom from CO_2 or other organic products.

At the University College in the Department of Heating and Ventilating Engineering, an effort is made to determine experimentally the law of pneumatics on a somewhat similar basis to that of electricity. A fundamental formula is taken in a form comparable to the Ohm's law, viz., $H = RQ^2$, and the validity of this law is experimentally tested in all kinds of pneumatic flow. To do this, special apparatus had to be devised, such as a large apparatus, a pneumatic analogue of the Wheatstone bridge, for the determination of specific resistance. This method is of great importance not only for the heating and ventilating engineer but also in many other lines; for example, specifying proper resistance in pneumatic units for a boiler flue or chimney will make it possible to deal on a rational basis with the problem of chimney shafts. By the application of such rules, we can determine what is the actual resistance of a boiler flue and what is the maximum capacity of a plant either in heat units or pounds of steam. To apply the method of power resistance to the determination of resistance of boiler flues and chimney shafts it is only necessary to attach a fan to the air inlet of the boiler through a chamber in which a constant low pressure of air can be maintained. An adjustable resistance between the fan and the boiler inlet is then allowed and the current measured in several cases, from which the pneumatic resistance can at once be established. In fact, it is even possible to determine the value of the resistance without a fan by having a very accurate micrometer gage, as the author shows. (40 pp., 8 figs. *gdA*).

UNIVERSITY OF ILLINOIS

Bulletin, vol. 12, no. 32, April 12, 1915, Urbana, Ill.

A STUDY OF BOILER LOSSES, A. P. Kratz.

Description of experiments undertaken to determine the conditions prerequisite for the continuous operation of the boilers in the new power plant at the University of Illinois and to permit a detailed study of the boiler and furnace losses, under varying conditions of load, depth of fuel bed and draft.

The boiler was operated as one of a battery of two boilers which delivered steam directly into the mains connected with the old plant. It was a Babcock & Wilcox boiler, designed to carry a working pressure of 160 lb. per sq. in. and having

two 42 in. by 20.33 ft. drums and 18 sections of 4 in. tubes, 18 ft. long, each section containing 14 tubes. The stokers were of the chain grate type, having an active grate surface of 90 sq. ft. The arch was 15 in. above the grates at the front and 33 in. at the back. The draft was produced by means of a brick chimney 175 ft. high, having an internal diameter of 10 ft. With a few modifications, the methods employed in these experiments were those of the A.S.M.E. Code for conducting boiler trials.

In the items in the tables there are added to those of the boiler test Code of the A.S.M.E., data on three efficiencies, viz., the efficiency of furnace and grate; the efficiency of the furnace, and the efficiency of the boiler exclusive of the furnace and grate. This was done because the efficiencies given in the A.S.M.E. Code are over-all efficiencies for the boiler and furnace together and do not afford a means of determining whether a loss in the efficiency of a unit is due to poor furnace construction, dirty tubes or faults in the boiler itself.

The following conclusions are drawn by the author from his tests: As regards the relation between thickness of fire, capacity and efficiency, it was found that the best efficiency under full load conditions was obtained with a fire of about 7 or 7.5 in., as this seemed to give a fuel bed resistance such that the normal amount of coal can be burned without excessive draft. For each load there seemed to be a well-marked thickness of fire which gave the best efficiency and, as the load decreased, this also became less; thus, for 1.25 load, the maximum efficiency occurred with 8 to 8.5 in. fire; for full load with 7 to 7.5 in. and, for $\frac{3}{4}$ load, with about 6.5 in.

The over-all efficiencies obtained were not surprisingly high, as under normal conditions of load and fire the over-all efficiencies have been about 65 per cent. The efficiency of the furnace and grate was fairly constant for all loads and depths of fuel bed. The losses in efficiency at higher loads were due to reduced heat absorption by the boiler and, in general, the lower boiler efficiencies coincide with the higher temperatures. As regards the amount of draft necessary, it is determined by three factors: the thickness of the fire, the amount of dust in the coal and the horsepower development. The 9.5 in. fire was found to invariably require the maximum draft for any given load. With thinner fires, sometimes one and sometimes another require more draft, depending largely upon the amount of dust and slightly varying horsepower. Between the limits of 24 to 32 lb. per sq. ft. of grate surface, and with a normal thickness of fire of about 7.5 in., it requires a draft of approximately 0.91 in. of water per lb. of coal per sq. ft. of grate surface per hour to burn Illinois screenings.

The relation between load, combustion and horsepower developed may be represented by a straight line. The percentage of excessive air decreases to a minimum and then increases again as the thickness of the fire increases. With thin fires, there is a marked tendency toward the formation of holes in the fuel bed through which an excessive amount of air can pass. Also, the entire fuel bed is more open and porous. The air is therefore not brought into as intimate contact with the incandescent surface of the coal as it otherwise would be, which leads to an excess of air. For fires less than 7.5 in. thick, the excess air increases when the load or rate of combustion is increased if a constant depth of fuel bed is maintained, while for fires above 7.5 in. thick, the reverse is true (72 pp., 31 figs. *e*).

MEETINGS

MINNESOTA, MAY 10

A joint meeting with the A.I.E.E. was held at the University of Minnesota on May 10 at which Mr. Brillhart of the Minneapolis General Electric Company gave a paper on the Lake Nokomis Electric Dredge and H. F. Teetsell of the Waldorf Box Board Company gave a paper on the Application of Electric Drive to Paper Mills and Data concerning the Paper Industry. Both papers were illustrated with lantern slides.

LOS ANGELES, JUNE 15

A meeting of the Los Angeles Section was held on June 15, it being a joint meeting with the Southern California Section of the A.S.C.E., the Los Angeles Section of the A.I.E.E., the A.S.C.E., the A.I.M.E. and A.S.C., The Southern California Chapter A.I.A. and the Engineers and Architects Association of Los Angeles. The subject of the meeting was Service of the Technical Man to the Community. The meeting was addressed by William Mulholland, Samuel Storrow and James A. B. Sherer.

CINCINNATI, JUNE 24

A joint meeting of the Cincinnati Section, A.S.M.E., and of the Engineers' Club of Cincinnati was held on the evening of June 24, 1915. Instead of the usual paper, a discussion took place on The Relations between the Valuation of Public Utilities and the Determination of Rates. There were three leaders of the discussion.

Mr. J. A. Lilly presented the point of view of the consulting engineer. He gave an impartial resume of the development of the various public service commissions and of the differences in opinion in the methods of physical valuation of properties. He dwelt for some time upon the intangible nature of franchise values and cited a number of cases in which supposedly able and honest engineers varied widely in their estimates of a given property.

Mr. O. F. Shepard presented the point of view of the consumer, who has had engineering training and experience. Mr. Shepard felt that large differences in valuations and contests over rates would occur as long as human nature does not undergo a violent change.

Mr. F. R. Healey presented the point of view of those who have been actively engaged in the operation of public utilities. Mr. Healey contended that time franchises have a value, even at their expiration; that is, that the value of the business as a growing concern is a real asset.

While no local instances were mentioned by the leaders of the discussion, certain public rates that are before the city council gave an added interest to the remarks of various speakers. The meeting was attended by about 100 members and guests.

NECROLOGY

JAMES TAGGART HALSEY

James Taggart Halsey was born in Philadelphia, Pa., in 1851, and was educated at the Episcopal Academy in that city. He was apprenticed in the Pennsylvania Railroad shops at Altoona, following which the railroad placed him in charge of its signals, and he made a number of basic inven-

tions of types of this railroad auxiliary. He resigned from service with the Company to take up a position with the Talbot Works, Richmond, Va., in which he continued for seven years. He later specialized in portable machine tools, maintaining a shop in Philadelphia. He was the inventor of the Halsey Motor Truck for trolley roads; this was a pioneer invention in this field, and one in which several prominent engineers displayed interest.

Mr. Halsey was elected to membership in the Society in 1885. He died in Philadelphia on April 27th, 1915.

JOSEPH AUSTIN HOLMES

Joseph Austin Holmes was born at Laurens, S. C., in 1859. He was educated at Cornell University, from which he was graduated Bachelor of Science in 1881. He became professor of Geology and Natural History at the University of North Carolina in the same year and continued as such until 1891. He was State Geologist from 1891 to 1903. In 1904 he was appointed by President Roosevelt as Chief of the U. S. Geological Survey Laboratories for the testing of fuels and structural materials, rendering noteworthy services. President Taft appointed him in 1910 head of the newly-created U. S. Bureau of Mines, and under his management great progress was made in perfecting methods of saving life in mines. The chief work of the Bureau under his direction has been the investigation of the cause of coal mine explosions, and one of his most important discoveries was that the dust from bituminous coal was more dangerous to miners than firedamp.

He received the degree of Doctor of Science from the University of Pittsburgh, and also of Doctor of Letters from the University of North Carolina, both being conferred upon him in recognition of effort in the mining industry.

He was a member of the American Institute of Mining Engineers, American Society for Testing Materials, the National Conservation Commission, and other organizations.

He was elected to membership in the Society in 1908. He died on July 13, 1915.

THOMAS DYSON WEST

Thomas Dyson West was born in Manchester, England, in 1851, and was the son of a niece of Dr. Michael Faraday. He was brought to America in childhood. At the age of twelve, he began the practical study of engineering at the Portland Locomotive Works, Portland, Me. In 1887, he organized the Thomas D. West Foundry Company, now known as the Valley Mold & Iron Company, of Sharpsville, Pa., and ten years later he founded the West Steel Casting Company. He was vice-president and general manager of the former until 1909, and was chairman of the board of directors of the latter until the time of his death.

Mr. West was the author of many books and papers on practical foundry work, publications which were basic in foundry literature and included "American Foundry Practice," "Moulders' Text Book," etc.

He established and used American Foundrymen's Standardized Drillings, which was taken over by the U. S. Bureau of Standardization in 1905. He was also the pioneer of the Safety First movement, and he organized the American Anti-Accident Society.

He was a member of the American Society for Testing Materials and was president of the American Foundrymen's Association in 1905-6. He was elected to membership in the

Society in 1884, and he died in Cleveland, Ohio, on June 18, 1915, from injuries received in an accident.

AUSTIN LORD BOWMAN

Austin Lord Bowman was born in Manchester, N. H., in 1861. He studied engineering at Yale University, and was graduated with the degree of Bachelor of Arts in 1883. For four years he specialized in construction and bridge work for western railroads, and in 1887, he came East and took up similar work with the Norfolk & Western Railroad. From 1890-1895 he was engineer and superintendent of construction for the American Bridge & Iron Company, Roanoke, Va. In 1897, he established himself in New York City as a consulting engineer on heavy railroad work. For six years, beginning 1901, he was consulting bridge engineer for the Central Railroad of New Jersey, reconstructing most of the important bridges on that road. In December 1907 he became consulting engineer of the Department of Bridges of New York City, and last summer was made chief engineer of the Department, a position which he retained until his death.

Mr. Bowman was a member of the American Society for Testing Materials, American Railway Engineering & Maintenance of Way Association, and the New York Railroad Club. He was a member of the American Society of Civil Engineers and a director from 1905-1907. He was elected to membership in the Society in 1899. He died on June 3, 1915.

PERSONALS

Maynard D. Church has accepted the position of assistant engineer of the Terry Steam Turbine Company of Hartford, Conn. He was until recently associated with the Dayton Turbine Pump Company, Cleveland, O., in the capacity of chief engineer.

Alfred J. Ormston, Jr., has accepted a position with the Jones & Laughlin Steel Company, Woodlawn, Pa., in the steam engineering department.

Alfred C. Brown, for the past four years general supervisor of equipment with the Edison Lamp Works of the General Electric Company, Harrison, N. J., has accepted the position of works manager with The Hopkins and Allen Arms Company of Massachusetts, factory located at Norwich, Conn.

F. H. Newell, consulting engineer U. S. Reclamation Service (Director 1907-1914, Chief Engineer, 1902-1907), has accepted the position of head of the civil engineering department of the University of Illinois, Urbana, Ill.

Lawrence B. Webster has completed his duties as engineer for the Committee on Appraisals of the Ohio Electric Light Association and has severed his connection with the American Gas and Electric Company of New York. He is now associated with Mandelbaum, Wolf and Lang, Cleveland, Ohio, managers of public utility and mining properties.

Richard C. Collins until recently connected with the United Shoe Machinery Company, Beverly, Mass., as mechanical engineer, is now associated with the Chelsea Fibre Mills, Brooklyn, N. Y., in the capacity of mechanical superintendent.

William H. C. Ramsey has accepted the position of general manager of The York Water Company, York, Pa. He was until recently associated with the Johnstown Water Company, Johnstown, Pa., in the capacity of superintendent.

Alfred S. Richardson has just completed a hydroaeroplane, of his own invention, which weighs 2300 lb. and has 2 six-cylinder Emerson engines of 68 actual h.p. each. The machine is the largest of its kind ever constructed and has two sets of planes, arranged in tandem, on each side.

The University of Toronto has recently conferred the new degree of D.Sc. upon T. Kennard Thomson. It is the first official recognition that the University of Toronto has shown a man in the engineering profession.

STUDENT BRANCHES

CORNELL UNIVERSITY

At a meeting of the Cornell University Student Branch on June 28, the following officers were elected for the following year: A. R. Cota, president; W. H. Rice, vice-president; W. F. Courtney, secretary and W. W. Robertson, treasurer.

KANSAS UNIVERSITY

The last meeting of the year of the Kansas University Student Branch was held on May 20 at the home of Prof. A. H. Sluss. The following officers for the coming year were elected: Jerry Stillwell, president; Burnette Bower, vice-president; A. J. Nigg, corresponding secretary; Charles Hagenbuch, recording secretary; Walter Pickering, treasurer; G. A. Rathert, chairman of the Program Committee; and Jerry Stillwell and S. E. Campbell, representatives on the Governing Board of Associated Engineering Societies.

STATE UNIVERSITY OF IOWA

The following officers have been elected for the coming year by the State University of Iowa Student Branch: C. W. Harrison, chairman; Max Kalen, vice-chairman and Victor Johnson, secretary and treasurer.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 18th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. In sending applications stamps should be enclosed for forwarding.

07 Chief draftsman to take charge of engineering department of St. Louis concern; man of sufficient ability and commercial experience to make success of the position; executive, with fundamental training in practical mechanical work of modern drawing office, machine shop, pattern shop and foundry practice, but must be commercial executive.

030 Agency wanted for small patented electrical device of foreign invention. Apply by number.

068 Young Engineer to take charge of tool department of Massachusetts concern manufacturing sterling silver hollow ware; one who understands machine shop practice generally, but more particularly a man familiar with up-to-date methods of working sheet metal, such as rolling, cupping, drawing and spinning; will have charge of laying out the tools to manufacture the goods, supervise the making and operation of the tools; knowledge of up-to-date methods of shop practice of advantage. Position has a good future for the right man.

069 Steam specialty salesmen who desire to take on a line of vacuum heating specialties can arrange for representing manufacturer. Representatives wanted in several leading cities. Apply through Society.

0101 Large manufacturing concern wishes to engage as employment head a man of special ability in the selection of labor; would be permanently located at the factory and should be able to select men of proper character, who would have the training for the work carried on in the various departments. State age, experience in full and salary wanted. Location Philadelphia. Name confidential.

0108 Head superintendent, for large European concern thoroughly posted in the manufacturing of rubber shoes, technical and surgical articles, covering for rollers, tubes of all kinds, balls, toys and similar articles to be made of hard or other rubber, etc. Apply by letter.

0116 Man who has had practical mechanical engineering education, with knowledge of electrical engineering, machine shop work, drafting, etc., desires technically educated assistant in the further development of plans for constructing an improved rock tunneling machine. Location New York.

0136 Good opportunity for first class designers; men with drawing office experience needed, particularly on heavy machine tools and similar machinery. Location, Pennsylvania.

0171 Competent designer for cane sugar machinery for large manufacturing concern. None but thoroughly experienced men need apply. State age, experience and salary expected. Give references. Location New York.

0172 Assistant works manager for Michigan firm manufacturing cranes and electrical specialties. Applicant must be high grade in ability and personality, with experience in structural, mechanical and electrical work and modern manufacturing methods. Name confidential.

0174 Capable man to take charge of manufacturing department of Massachusetts concern. Experience not expected in particular line of work, which is the manufacture of spectacles and eyeglasses, but some manufacturing experience required on small accurate work. Applicant must show that he has ability to handle men and get results at a fair cost. Salary \$1800 per year. Apply by letter.

0176 Power transmission salesman for New York concern manufacturing pulleys, shaft-couplings, collars, etc.

0177 Engineering draftsman who can handle general power plant work. Technical school man who has had three or four years experience in an engineering office. Location New Jersey.

0180 Firm of constructing engineers desires to add to its staff several good mechanical and electrical engineers. Location New England. Name confidential.

0181 Shop superintendent experienced in deep drawing of brass wanted for concern in New York State. Apply by letter.

0184 Superintendent of a shop employing one hundred and fifty men in the forging of steel tools; will have complete charge of the manufacturing and labor and should be able to plan and lay out new work. Initial salary \$2000 to \$2500. Subsequent figure will depend entirely upon results obtained. Location East. Apply by letter. Name confidential.

0188 Chief draftsman on steam or gas engineering. Location Jersey City, N. J.

0189 Draftsman for industrial and power plant, layout of machinery and structural building design. American. Salary \$150 a month. Location Pennsylvania. Name confidential. Apply by letter.

0190 Foreman for European concern (listed in 0108) manufacturing articles of hard or other rubber. Apply by letter.

0192 Production Engineer or mechanical superintendent for pulp mill; man with technical training and practical experience; one who is familiar with modern methods of ma-

chine shop management. Name confidential. Apply by letter.

0195 Assistant Professor in department of mechanical engineering. Salary \$1500. To teach Machine Design and allied subjects. Must have completed a course in mechanical engineering; some practical experience as well as successful teaching experience. Location Texas.

0197—Wanted—Engineer, assistant required for large maintenance department experience, along lines of power station work, millwright and piping, drafting and cost estimating. Position pays \$20 to \$25. Location Massachusetts. Replies must be written on one page and confine answer to the following: name; age; nationality; education; experience; references.

0198 Instructor in mechanical laboratory work. Salary \$1,000 for the college year, with prospects of some increase if engagement is renewed at the end of the year. One who has had some teaching experience in the line indicated. Location Middle West.

0199 Young refrigerating engineer, preferably one who has had some experience in the field, as a salesman and a general man with engineering knowledge to call and talk things over with customers; until the man's ability has been proved, salary ranging about \$25 per week. Location Ohio.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated in consecutive issues of the Bulletin. Names and records are kept on the office list three months, and at the end of such period if desired must be renewed.

H-206 Junior member, mechanical graduate 1907, experienced in advertising and publication work, is open for position as publicity agent or advertising manager. Moderate salary at beginning if position is desirable otherwise.

H-207 Mechanical engineer, well qualified by technical education, experienced in research along lines of engineering physics, desires position involving industrial research or experimental engineering. Would also consider position as salesman on the road.

H-208 Member, mechanical and electrical engineer, formerly U. S. navy inspector, eleven years experience in design and construction of power and industrial plants, testing machinery, technical writing, desires change, preferably with New York consulting engineer or contractor. At present employed.

H-209 Member, age 42, graduate of Stevens Institute of Technology, 1893, with fifteen years general experience, from draftsman up through executive management, followed by seven years specializing in organization and efficiency work in both manufacturing and commercial ends in a wide variety of lines, including manufacture of chocolate, machine shop, underwear, wholesale news distribution, brass goods, foundry, paper boxes, printing and publishing, to avoid continual traveling, desires a permanent connection with a progressive concern, location preferred New York or vicinity. Will invest if conditions are favorable. Available about October 1st.

H-210 Member, Cornell graduate, age 31, married, eight years experience in refrigerating engineering, design and supervision of heat, light and power plants, desires position with consulting engineer or with private firm.

H-211 Member, who has specialized in elevator and hoisting machinery, including motor and control, also conveying and handling machinery and the special structure required in this line, experienced in drafting room, shop, field and estimating, desires position as executive or sales engineer. Can take up sales proposition with technical or non-technical customers and see the work through to completion.

H-212 Member, mechanical and electrical engineer, twelve years experience as combustion engineer, power house tester,

chief electrician and mechanic, desires position. Location immaterial. Speaks Spanish fluently.

H-213 Student member, 1915 graduate of Columbia University, in mechanical engineering, desires a position in or around New York which offers an opportunity to start in the engineering profession. Salary secondary consideration.

H-214 Junior, power and designing engineer, seven years practical experience in power plant design and operation, heating, ventilating, electric light and power, refrigeration, fire protection, reports, plans and specifications, desires position.

H-215 Member, graduate M.E., age 35, ten years in an executive position as technical writer and correspondent of technical subjects of a consulting engineering nature, teaching experience, also experience as practical machinist. At present employed, but open for engagement.

H-216 Junior member, M.E., five years experience in design and manufacture of stationary oil engines, two years experience in power plant work and general equipment, desires position with consulting engineer. Will consider any opening which may lead to responsible position. Location immaterial.

H-217 Graduate, Massachusetts Institute of Technology, successful in organizing in both production and business departments, is qualified to assume responsibilities of manager or assistant in plant where special executive capacity and manufacturing experience are required.

H-218 Technical graduate, age 33, ten years experience in boiler manufacture and general plate work, desires position as manager or assistant manager. At present employed.

H-219 Associate-member, age 27, Stevens graduate, six years experience in gas engine, designing, experimental, testing, and every department of machine shop, desires position as assistant to executive or other responsibility.

H-220 Associate-member, Cornell M.E., age 32, four years experience steam and efficiency engineering, one and one half years as master mechanic, capable of handling men, now holding manufacturing executive position, desires chance for more rapid advancement.

H-221 Student member, technical man, Purdue University, age 26, engineering experience, with initiative and executive ability, desires position as sales engineer or assistant to chief engineer. Location middle West preferred.

H-222 Associate-member, technical graduate, nine years practical experience in foundry, machine shop and assembling work; time study and time setting for prominent machine tool manufacturer, now employed traveling as high speed expert and adviser, desires position as superintendent or similar executive where opportunity is offered to acquire an interest in the business. Location preferred middle West.

H-223 Mechanical engineer, five years practical experience in steam turbines, power plant equipment, and layouts, also construction work and reinforced concrete, desires permanent position. At present employed.

H-224 Junior member, Stevens graduate, desires to associate with engineering firm or patent attorney. Opportunity for future considered before salary.

H-225 Junior member, age 27, graduate in mechanical engineering, three years experience in testing and operation of power plants, several years in editorial and office work, desires position as secretary or assistant to manager. At present employed. Location preferred New York.

H-226 Student member, 1914 M.E. graduate, desires position in engineering or experimental department of company manufacturing corn harvesting machinery or other agricultural implements. Location preferred middle West. At present employed in gas tractor company.

H-227 M.E. specialized on combustion of soft coal, has had experience as machinist, draftsman, engineer of coke works and chief engineer of large manufacturing concern, desires position with boiler, stoker or furnace manufacturer.

H-228 Student member, 1915 M.E. graduate, two years accounting experience, also field work on dredging machinery, drafting and salesman, desires position with manufacturing concern with chance for advancement. Location preferred New York or New England states.

H-229 Member, age 33, twelve years experience, six years with present company, is seeking position with opportunity for advancement, as mechanical engineer or charge of drafting room. Has good designing ability.

H-230 Member, graduate engineer, age 35, American, capable designer, practical foundry and shop man, experienced in modern production methods and management, has had broad engineering experience in Europe and America as mechanic and executive in design and manufacture of engines, heavy machinery, machine tools, automatic machinery and light high grade specialties, desires position as chief engineer, superintendent, manager or assistant. Location immaterial, salary commensurate with position.

H-231 Graduate M.E., at present employed as sales engineer and designer in heating and ventilation and power plant lines, thoroughly acquainted with vacuum heating systems, desires position in the same or along similar lines.

H-232 Graduate mechanical engineer, age 28, five years practical work prior to college course and two years subsequent thereto, wishes a teaching position in Eastern or Southern college or university in experimental engineering, mechanics or physics.

H-233 Japanese member, graduate of electrical and mechanical school in 1903, connected with telephone and railroad companies of New York City, intending to visit Japan next autumn, wishes to communicate with American firms planning to develop their business in Japan or China. Will consider agencies or commission. First class references will be furnished responsible parties interested.

H-234 Member, age 45, designing engineer and master mechanic, American, speaking French and German, desires position. South preferred. At present employed.

H-235 Member, with an unusually thorough experience in manufacture, and first class record as executive, at present in successful consulting practice in scientific management, and especially successful in developing capable men, desires manufacturing executive position.

H-236 Superintendent, twenty years mechanical and executive experience on small interchangeable work, competent to design tools and fixtures for increasing production and reducing costs. At present employed.

H-237 Member, age 33, married, graduate of the United States Naval Academy, several years active service in the United States Navy, desires operating executive position with manufacturer of arms and ammunition. Salary \$4,000. Location immaterial. At present employed.

H-238 Junior member, Columbia graduate M.E., 1913, two years experience in production and drafting departments, desires position in New York with chance for advancement. At present employed.

H-239 Member, in consulting practice, with broad experience in perfecting general organization of manufacturing companies and in efficient operation of plants, including familiarity with various processes of manufacture, particularly metal working, is open for temporary or permanent connection. Under suitable conditions will take stock or interest in profits as part compensation for services.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE. Pamphlet nos. 4-20. *Washington, 1915*. Gift of Carnegie Endowment for International Peace.

CHICAGO RAILWAY TERMINAL COMMISSION. Preliminary Report submitted to City Council Committee on Railway Terminals, March 29, 1915. Gift of John F. Wallace.

CHICAGO TRACTION. Board of Supervising Engineers. 6th Annual Report, 1913. *Chicago, 1915*. Gift of Blon J. Arnold.

CITY OF NEW YORK. Bureau of Buildings. Report, 1914. New York. Gift of Bureau of Buildings.

"HÜTTE" DES INGENIEURS TASCHENBUCH. Herausgegeben vom Akademischen Verein Hütte E. V. 22d edition. 3 vols. *Berlin, William Ernst & Sohn, 1915*. Gift of Publisher.

This, the most extensive of all engineering handbooks, is a monument to German thoroughness. The three volumes of a thousand pages each contain tables, diagrams, formulae and data on every conceivable engineering subject, and all are very carefully indexed.
W. P. C.

ILLINOIS SOCIETY OF ENGINEERS AND SURVEYORS. 30th Annual Report, 1915. *Wheaton, 1915*. Gift of Illinois Society of Engineers and Surveyors.

INDUSTRIAL RESOURCES AND OPPORTUNITIES OF THE SOUTH. By Arthur D. Little. *Boston, 1915*. Gift of Author.

INDUSTRIELLE GESELLSCHAFT VON MÜLLHAUSEN. Jahresbericht, 1914. *Strassburg, 1915*. Gift of Industrielle, etc.

NATIONAL FOREIGN TRADE CONVENTION. 2d Official Report, 1915. *New York City, 1915*. Gift of Robert H. Patchin.

OFFICIAL TESTS OF 340 HORSE POWER WATER TUBE BOILER AND AUXILIARIES. (Report.) Harrison Street Pumping Station. *Chicago, March 20, 1915*. Gift of City of Chicago Public Works.

OREGON AGRICULTURAL COLLEGE. The Trail Blazers. *Corvallis, Ore.* Gift of College.

PIPE DISTRIBUTION SYSTEMS. N. S. Hill, Jr. Reprinted from Journal of the American Water Works Association, March, 1915. Gift of Author.

FREDERICK W. TAYLOR, MEMORIAL. Spoken at Cedron, Indian Queen Lane, Germantown, Philadelphia, March 24, 1915. Gift of Morris L. Cooke.

WESTERN RAILWAY CLUB. Official Proceedings. Vol. 26. *Chicago, 1913-14*. Gift of Western Railway Club.

GIFT OF ALFRED O. BLAISDELL

UNITED STATES NAVY. Marine Engines for Screw Propulsion, drawn by A. O. Blaisdell. Brooklyn, 1909.

Mr. Blaisdell, who presents these drawings, was connected with the Bureau of Steam Engineering at the Brooklyn Navy Yard, for a number of years. The drawings are Mr. Blaisdell's own work, being copies of scale drawings of all the marine screw engines of the United States Navy from the time of the Princeton to the Miantonomah. These are all drawn to the scale of 32" to 1 foot, with a lettered description of each. They are a distinct contribution to the early history of marine engines in this country.

THE ARGUMENT OF EDWARD N. DICKERSON, WITH HIS NOTES AND EXPLANATIONS; THE CHARGE OF JUDGE NELSON, AND THE VERDICT OF THE JURY, IN THE CASE OF SICKELS VS. BORDEN. *New York, 1856*.

THE STEVENS BATTERY, 1850-1875.

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

COMING MEETINGS OF THE SOCIETY

September 16 and 17, San Francisco, Cal. In common with the other national engineering societies, professional sessions will be held in San Francisco, September 16 and 17, previous to the meetings of the International Engineering Congress, which will occur during the week of September 20. Papers will be presented on the Exhibits and Engineering Features of the Panama-Pacific International Exposition, and on Oil Engines, with special reference to their use with California oils. The sessions will be held in the Hall of the Native Sons of the Golden West, Mason Street, between Geary and Post Streets. The headquarters of the Society will be at the Clift Hotel.

October 6, St. Louis, Mo. Subject: The Little River Drainage District, by William A. O'Brien.

October 27, St. Louis, Mo. Subject: Telescopes, by Dr. John A. Brashear.

Annual Meeting, December 7-10, New York City. Arrangements have already been perfected for sessions by the sub-committees on Railroads, Textiles, and Protection of Industrial Workers and it is expected that papers will also be contributed by the Committees on Machine Shop Practice, Industrial Buildings, and Air Machinery, besides the usual miscellaneous papers. The Railroad session will be devoted to a discussion of trucks for passenger coaches. The Textile session will have papers by engineers prominent in the textile field on the relative values of purchased electric current, and of power from individual plants; hot water heating for textile mills; and the engineering features of insurance. The session on Safety Methods will be of interest to engineers generally. It is planned to have a discussion along broad lines, taking up the principles involved and the results obtained by safety methods, and their bearing on industry as a whole.

THE SAN FRANCISCO MEETING AND THE INTERNATIONAL ENGINEERING CONGRESS, 1915

AS the time approaches for the September meeting and the International Engineering Congress, interest is centered on the programs of papers to be presented and on the other activities that have been scheduled. A complete account appeared in the August issue of The Journal of the preliminary affairs in connection with the meetings, such as the transportation arrangements, the headquarters and hotel accommodations, the meetings of other societies, the excursions, the Exposition, etc., but little was definite relative to the program of the meetings at that time. The programs of both the September meeting of the Society and of the International Engineering Congress have now been established and they are presented herewith in complete form.

TRANSPORTATION

As announced in The Journal for August, arrangements have been made for a special train from New York to San Francisco, for members of the Society and their friends, leaving New York (Grand Central Terminal) on Thursday, September 9, at 7.45 p.m. The train will stop at Niagara Falls for four hours on Friday morning, to permit of sightseeing. On Sunday morning the party will arrive at Colorado Springs, where side trips may be made to Crystal Park, Pike's Peak, Garden of the Gods, Cheyenne Canyon and the Seven Falls. The Grand Canyon will be reached on

PROGRAM OF THE SEPTEMBER MEETING

*Headquarters at Clift Hotel, San Francisco,
September 16 and 17.*

*Meetings in Hall of the Native Sons of the
Golden West, Mason Street, between
Geary and Post Streets.*

THURSDAY, SEPTEMBER 16.

Address of welcome by a leading citizen of San Francisco and response by the Vice-President, G. W. Dickie.

ENGINEERING FEATURES OF THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION, G. L. Bayley.

MECHANICAL ENGINEERING AT THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION, G. W. Dickie.

FRIDAY, SEPTEMBER 17.

THE HEAVY OIL ENGINE, ITS PRESENT STATUS AND FUTURE DEVELOPMENT, A. H. Goldingham.

THE DIESEL ENGINE AND ITS APPLICATION IN SOUTHERN CALIFORNIA, W. H. Adams.

THE STRENGTH OF GEAR TEETH, G. H. Marx and L. E. Cutter.

Tuesday morning and fifteen hours will be spent there, giving ample time for excursions to Bright Angel Trail, Bottom of Canyon, Hopi Point, Hermit Rim Drive and Sunset Point. The party will arrive at San Francisco on Wednesday, September 15, at 9 a.m.

Reservations for this train are now being arranged by Mr. G. S. Harner, Passenger Agent, New York Central Lines, 1216 Broadway, New York City. The fare to San Francisco by this train and return by any route (except via Northwestern points) is \$98.80. Pullman rates, one way, are quoted as follows: lower berth, \$22.00; upper berth, \$17.60.

For those members of the Society who cannot join the

party from New York, reservations are being made on the Sunset Limited, leaving New Orleans on Sunday, September 12, at 11 a.m., and arriving in San Francisco at 1.00 p.m. on Wednesday, September 15. Accommodations on this train can now be secured by addressing Mr. J. H. R. Parsons, General Passenger Agent, Southern Pacific Company, New Orleans, La. The round trip fare, New Orleans to San Francisco, is \$57.50 going and returning over the same route. Pullman rates, one way, are quoted as follows: lower berth, \$11.50; upper berth, \$9.20.

HEADQUARTERS

The headquarters of the Society will be the Clift Hotel, at the corner of Geary and Taylor Streets, San

Francisco. For members who desire to be accommodated at this hotel, a number of rooms have been arranged for at a rate of \$5.50 per room, including bath, to be occupied by one or two persons. Each member should make his own reservation direct with the hotel, mentioning the Society.

For convenience, the rates at other hotels as quoted to the Society are given below:

Palace Hotel, Market and New Montgomery Streets, \$4.00 per day, room and bath, one person.

Fairmont Hotel, California and Mason Streets, \$4.00 per day, room and bath, one person.

Hotel St. Francis, Geary and Powell Streets, \$7.00 per day up, room and bath, two persons.

Hotel St. Regis, 83 Fourth Street, \$2.50 per day up, room and bath, two persons.

Information regarding accommodations at any other hotels may be obtained by addressing the Official Exposition Hotel Bureau, 702 Market Street, San Francisco. This Bureau also undertakes to make reservations in approved hotels without charge.

It is also worthy of note that the Committee on Local Affairs in San Francisco has placed its services at the disposal of all engineers resident within the United States, so that those who visit San Francisco with their families and friends may be sure that special attention will be paid to their comfort.

INTERNATIONAL ENGINEERING CONGRESS, 1915

The efforts of the Committee of Management of the Congress have been indefatigable to secure the success of the enterprise by the cooperation of members from the national engineering societies. The last report of this committee announced that practically three thousand members had been enrolled and 240 papers have been received.

Members of the Society still have an opportunity of enrolling in the Congress if they desire to do so. The fee, which is five dollars, entitles the subscriber to a certificate of membership, to participation in the deliberations of the Congress, to an index volume of the Proceedings, and to one of the volumes to be published by the Congress. Remittances may be made to W. A. Cattell, Secretary, Foxcroft Building, San Francisco.

The Congress will publish ten volumes of proceedings on the topics under which the program is divided as follows: The Panama Canal; Waterways, Irrigation; Municipal Engineering; Railways, Railway Engineering; Materials of Engineering Construction; Mechanical Engineering; Electrical Engineering, Mechanical Engineering; Mining Engineering, Metallurgy; Naval Architecture and Marine Engineering; Miscellaneous, including Military Engineering, Aeronautical Engineering, and Heating and Ventilation.

The Congress will be opened at 10 A.M. on Monday,

September 20, in the new Auditorium Building, where the subsequent sessions will be held. At the opening session there will be addresses of welcome and responses, an address by General George W. Goethals, Honorary President, and the presentation of the John Fritz Medal to Dr. James Douglass. Below is presented the complete program of the Congress.

PROGRAM OF THE INTERNATIONAL ENGINEERING CONGRESS, 1915

SAN FRANCISCO, CALIFORNIA, SEPTEMBER 20-25

All sessions are to be held in the Auditorium Building, Civic Centre, Hayes and Larkin Streets, at Market Street.

OPENING GENERAL SESSION.

Monday, Sept. 20, 10 a.m.

Address of welcome by the Mayor of San Francisco.

Addresses by General Goethals, Honorary President of the Congress, by Vice Presidents and by distinguished delegates.

Presentation of John Fritz Medal to Dr. James Douglas.

THE PANAMA CANAL

GENERAL SESSION.

Monday, Sept. 20, 2 p.m.

Introductory Chapter, General G. W. Goethals.

Commercial and Trade Aspects of the Panama Canal. Emory R. Johnson.

The Working Force of the Panama Canal, Captain R. E. Wood.

Purchase of Supplies for the Panama Canal, F. C. Boggs.

Outline of Canal Zone Geology, Donald F. MacDonald.

Climatology and Hydrology of the Panama Canal, F. D. Willson.

WATERWAYS

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

The Province of Waterways in the Internal Commerce and Development of a Country, Brigadier-General W. H. Bixby, U. S. A.

Artificial Waterways and Natural Channels and Bodies of Water linked by Artificial Channels, constituting Inside Routes, C. S. Riche.

The Waterway from the German Rhine through the Netherlands to the North Sea along the Rivers Rhine, Waal and Nieuwe Mass, C. A. Jolles.

Natural Waterways in the United States, Lieut.-Col. Wm. W. Harts.

SESSION 2.

Tuesday, Sept. 21, 2 p.m.

Flood Control, H. M. Chittenden.

Flood Control in China, Charles Davis Jameson.

Works for the Improvement of Navigable Estuaries, Prof. Dr. Luigi Luiggi.

The River Improvement Works in Japan, Tadao Okino.

SESSION 3.

Wednesday, Sept. 22, 10 a.m.

Dry Excavation, General G. W. Goethals.

Dredging in the Panama Canal, W. G. Comber.

Construction of Gatun Locks, Dam and Spillway, Brig.
General W. L. Sibert.
Method of Construction of the Locks, Dams and Regulating
Works in the Pacific Division of the Panama Canal,
S. B. Williamson.

SESSION 4.

Wednesday, Sept. 22, 2 p.m.

Lock Gates, Chain Fenders and Lock Entrance Caissons,
Henry Goldmark.
Emergency Dams above Locks of the Panama Canal, T. B.
Monniche.
Design of the Lock Walls and Valves of the Panama Canal,
L. D. Cornish.

SESSION 5.

Thursday, Sept. 23, 10 a.m.

The General Design of the Locks, Dams and Regulating
Works of the Panama Canal, Brig. General H. F.
Hodges.
The Design of the Spillways of the Panama Canal, E. C.
Sherman.
Hydraulics of the Locking Operations of the Panama Canal,
R. H. Whitehead.

IRRIGATION

SESSION 6.

Thursday, Sept. 23, 2 p.m.

Irrigation Enterprise in the United States, C. E. Grunsky.
Economic Advisability of Irrigation, F. H. Newell.
Distribution Systems, Methods and Appliances in Irriga-
tion, J. S. Dennis, H. B. Muckleston and R. S. Stockton.
Italian Irrigation, Prof. Luigi Luiggi.
Irrigation in Lybia (Italian Colony), Prof. Luigi Luiggi.

SESSION 7.

Friday, Sept. 24, 10 a.m.

Utilization of Underground Waters, G. E. P. Smith.
Irrigation in India, M. Nethersole.
Dams, Arthur P. Davis, D. C. Henny.
Earthen Dams, William Lumsden Strange.

SESSION 8.

Friday, Sept. 24, 2 p.m.

The Distribution of Water in Irrigation in Australia, El-
wood Mead.
The Co-relation between Annual Demand and Supply from
Natural Flow, with a Study of the Amount of Storage
Necessary, L. C. Hill.
Irrigation in Spain, Distribution Systems, Methods and Ap-
pliances, J. C. Stevens.
Irrigation in Spain, Regulations Controlling the Use of
Water, Metering Water for Irrigation and Methods of
Charging, J. C. Stevens.

SESSION 9.

Saturday, Sept. 25, 10 a.m.

The Problem of Irrigation in the Argentine Republic, Car-
los Wauters.
Duty of Water in Irrigation, Samuel Fortier.
Drainage as a Correlative of Irrigation, C. G. Elliott.

MUNICIPAL ENGINEERING

SESSION 1.

Tuesday, Sept. 21, 2 p.m.

City Planning, Nelson P. Lewis.
London Traffic in 1913, Sir Albert Stanley.
Transit Problem in American Cities, W. F. Reeves.

SESSION 2.

Wednesday, Sept. 22, 10 a.m.

Recent Progress and Tendencies in Municipal Water Sup-
ply in the U. S., J. W. Alford.
Municipal Water Supply in France, Belgium, Algeria-
Tunisia, Dr. E. Imbeaux.
The Disposal of Suspended Matters in Sewage, Rudolph
Hering.
Sewage for Low Countries with Special Regard to the
Town of Amsterdam, A. W. Bos.

SESSION 3.

Wednesday, Sept. 22, 2 p.m.

Streets, George W. Tillson.
Rural Highways, L. W. Page.
Rural Highways, L. Limasset.
Construction and Maintenance of Rural Highways, Alfred
Dryland.
Rural Highways, Arthur Gladwell.
The Struggle Against Dust, C. C. Dassen.

SESSION 4.

Friday, Sept. 24, 10 a.m.

Utilities, Dr. A. C. Humphreys.
Short Paper on Public Utilities, Edward Willis.
Arch Bridges of Hooped Cast Iron, Dr. Ing. Fritz von Em-
perger.

SESSION 5.

Friday, Sept. 24, 2 p.m.

Preliminary Municipal Engineering at Panama, Henry
Welles Durham.
Municipal Engineering and Domestic Water Supply in the
Canal Zone, George M. Welk.
Sanitation in the Panama Canal Zone, Charles F. Mason.
"Soliditit" Concrete Roads in Italy, Prof. Luigi Luiggi.

RAILWAY ENGINEERING

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

The Status of the Railways of North and South America,
F. Lavis.
Italian Railways, Prof. Luigi Luiggi.
The Status of Indian Railways, Victor Bayley.
The Status of Chinese Railways, Charles Davis Jameson.
The Status of Russian Railways, V. A. Nagrodsky.
The Status of Railways and Tramways in the Netherland
East Indies, E. P. Wellenstein.

SESSION 2.

Tuesday, Sept. 21, 2 p.m.

Economic Considerations Controlling and Governing the
Building of New Lines, John F. Stevens.
The Locating of a New Line, William Hood.
The Reconstruction of the Panama Railroad, Frederick
Mears.
The Locating of a New Line, David Wilson.
Railway Construction Methods and Equipment in Aus-
tralia, Maurice E. Kernot.

SESSION 3.

Thursday, Sept. 23, 10 a.m.

American Railroad Bridges, J. E. Greiner.
Tunnels, Charles S. Churchill.
Tunnels in Italy, Prof. Luigi Luiggi.
Tunnels in Switzerland, R. Winkler.
Track and Roadbed, George H. Pezram.

SESSION 4.

Thursday, Sept. 23, 2 p.m.

Recent Locomotive Development, George R. Henderson.
Rolling Stock (other than Motive Power), A. Stucki.
The Floating Equipment of a Railroad, F. L. DuBosque.
Railroad Terminals, B. F. Cresson, Jr.

SESSION 5.

Friday, Sept. 24, 10 a.m.

Electric Motive Power in the Operation of Railroads, William Hood.
Electric Motive Power in the Operation of Railroads, E. H. McHenry.
Signals and Interlocking, Charles Hansel.

MATERIALS OF ENGINEERING CONSTRUCTION

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

Structural Timber in the United States, H. S. Betts, W. B. Greeley.
Timber in Canada, R. H. Campbell.
Indian Timbers used in Engineering Construction, R. S. Pearson.
Timber in Russia, Mr. Tkachenko.
Preservative Treatment of Timber, Howard F. Weiss, Clyde H. Teesdale.

SESSION 2.

Tuesday, Sept. 21, 2 p.m.

Clay Products as an Engineering Material, A. V. Bleininger.
Aggregates for Concrete, S. E. Thompson.
Probable and Presumptive Life of Concrete Structure made from Modern Cements, Bertram Blount.
Volume Changes in Concrete, Alfred H. White.
Use of Wood and Concrete in Structures standing in Sea Water, with Special Reference to Dock Work, Harrison S. Taft.

SESSION 3.

Wednesday, Sept. 22, 10 a.m.

The Outlook for Iron, Prof. James Furman Kemp.
Alloy Steels in Bridgework, J. A. L. Waddell.

SESSION 4.

Thursday, Sept. 23, 10 a.m.

The Economics of the World's Supply of Copper, Thomas T. Read.
Consumption of Copper and its various Uses, Thomas T. Read, H. D. Hawks.
Alloys and their Use in Engineering Construction, W. Remben Webster.
The Engineering Uses of Aluminum, Prof. Jos. W. Richards.

SESSION 5.

Thursday, Sept. 23, 2 p.m.

Testing of Materials, R. G. Batson.
Testing Full Size Members, Gaetano Lanza.
Proof Testing of Structures, J. E. Howard.

MECHANICAL ENGINEERING

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

Recent Advances and Improvements in Founding, Thomas D. West (deceased).
Forgings from the Early Times until the Present, C. von Philip.

Recent Progress and Present Status of the Art of Forging with Special Reference to the Use of Quick-Acting Forging Presses, A. J. Capron.

Permanent Shops, Pacific Terminals, Panama Canal, H. D. Hinman, A. L. Bell.

SESSION 2.

Tuesday, Sept. 21, 2 p.m.

Machine Shop Equipment, Methods and Processes, E. R. Norris.
Machine Shop Equipment, Methods and Processes, H. F. L. Orentt.
Automatics, R. E. Flanders.
High Temperature Flames in Metal Workings, H. R. Swartley, Jr.

SESSION 3.

Wednesday, Sept. 22, 10 a.m.

The Gas Power System. A Survey of its Status in the Year 1915, Professor Charles Edward Lucke.
The Development of the Construction of Turbines in the Netherlands, D. Dresden.
The 1915 Steam Turbine, E. A. Forsberg.
The Diesel Engine in America, Max Rotter.

SESSION 4.

Thursday, Sept. 23, 2 p.m.

Developments in Modern Water Turbine Practice, Dr. H. Zoelly.
Water Wheels of Pressure Type, Arnold Pfau.
Hydraulic Power Development and Use, J. D. Galloway.
Water Wheels of Impulse Type, W. A. Doble.
Canadian Hydraulic Power Development, Charles H. Mitchell.

SESSION 5.

Friday, Sept. 24, 10 a.m.

Safety Engineering, Frederick Rensen Hutton.
Motor Vehicles, Passenger Type, Ethelbert Favary.
Motor Vehicles, Utility Type, A. J. Shade.
Motor Tractors, F. S. Davis.

SESSION 6.

Friday, Sept. 24, 2 p.m.

The Boiler of 1915, Arthur D. Pratt.
Compressed Air in the Arts and Industries, W. L. Saunders.
Equipment, Processes and Methods for Boiler Shop, E. C. Meier.

ELECTRICAL ENGINEERING

SESSION 1.

Wednesday, Sept. 22, 2 p.m.

Economics of Electric Power Station Design, H. F. Parrshall.
The Water Power of Sweden, Sven Lubeck.
Electric Power in Canadian Industry, Charles H. Mitchell.
The Effect of Hydro-Electric Power Transmission upon Economic and Social Conditions, Frank G. Baum.

SESSION 2.

Thursday, Sept. 23, 10 a.m.

Electrical and Mechanical Installations of the Panama Canal, Edward Schildbauer.
Electric Welding, C. B. Auel.
The Application of Electricity to the Heating of Metals, F. L. Bishop.
The Electric Motor as an Economic Factor in Industrial Life, David R. Rushmore.

SESSION 3.

Thursday, Sept. 23, 2 p.m.

- The Influence of the Electric Motor on Machine Tools, A. L. DeLeeuw.
Effects of Electrolysis on Engineering Structures, Albert F. Ganz.
The Mechanical Problem of the Electric Locomotive, G. M. Eaton.
On the Production of High Permeability in Iron, Ernest Wilson.

MINING ENGINEERING

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

- Economic and Social Influence of Mining, W. H. Shockley.
Valuation of Metal Mines and Prospects, T. A. Rickard.
The Valuation of Oil Lands and Properties, M. E. Lombardi.
Valuation of Coal Mines and Lands, R. V. Norris.
Valuation of Anthracite Mines, R. V. Norris.
Valuation of Coal Lands, Samuel A. Taylor.
Evaluating Coal Properties in Western Canada, R. W. Conthard.
Valuation in France, E. Gruner.

SESSION 2.

Wednesday, Sept. 22, 10 a.m.

- Functions and Work of Exploration and Development Companies, H. W. Turner.
European Mining Finance, J. L. Gallard.
The Financing of Mines in the United States, Lucius W. Mayer.

SESSION 3.

Wednesday, Sept. 22, 2 p.m.

- Organization and Staff of Mining Companies, W. H. Shockley, R. E. Cranston.
Relations of Governments to Mining, Horace V. Winchell.
Mine Inspection, J. W. Paul.

METALLURGY

SESSION 1.

Tuesday, Sept. 21, 2 p.m.

- Symposium on Iron and Steel, edited by Henry M. Howe.
Iron and Steel Castings, John Howe Hall.
Metallography and the Hardening of Steel, Albert Sauvour.
Case Hardening of Steel, F. Giolitti.
The Duplex Process of Steel Manufacture, F. F. Lines.
Methods of Preventing Piping in Steel Ingots, Emil Gathmann.

SESSION 2.

Thursday, Sept. 23, 10 a.m.

- Symposium on Copper, edited by E. P. Mathewson.
Process in Copper Metallurgy, Thomas T. Read.
Advances in Copper Smelting, Frederick Laist.
Metallurgy of Copper in Japan, R. Kondo.
Copper Metallurgy of the Southwest, Dr. James Douglas.
Reduction Works, Copper Queen Consolidated Mining Company, Douglas, Arizona, Forest Rutherford.
Advances made in the Metallurgy of Copper, Globe District, Arizona, L. O. Howard.
Improvements in Design and Construction of Modern Copper Plants, Chas. H. Repath.

SESSION 3.

Thursday, Sept. 23, 2 p.m.

- Symposium on Copper (Continued).
Leaching Copper Ores, W. L. Austin.
The Metallography of Copper, William Campbell.

- Boronized Cast Copper, Dr. E. Weintraub.
Electrolytic Refined Copper, A. C. Clark.
The Development of Electrolytic Copper Refining, Lawrence Addicks.
Physical Properties of Copper, Carle R. Hayward.

SESSION 4.

Friday, Sept. 24, 10 a.m.

- Symposium on Gold and Silver, edited by C. W. Merrill.
Coarse Crushing Plant; 1,000 tons capacity, G. O. Bradley.
Crushing and Grinding, L. D. Mills, M. H. Knyla.
Solution of Gold and Silver including Classification, M. H. Knyla.
Filtration or Separation of Metal Bearing Solution, L. D. Mills.
Precipitation, G. H. Clevenger.

SESSION 5.

Friday, Sept. 24, 2 p.m.

- Symposium on the Metallurgy of Zinc, edited by Walter Renton Ingalls.
Some Main Points in the Economics of the Metallurgy of Zinc, Walter Renton Ingalls.
The Development of Zinc Smelting in the United States, George C. Stone.
The Smelting and Refining of Lead, Dr. H. O. Hofman.
Symposium on the Utilization of Fuels in Metallurgy, edited by C. H. Fulton.
Pulverized Coal in Reverberatory Furnaces, D. H. Browne.
Burning Pulverized Coal in Copper Reverberatories, E. P. Mathewson.
Gas Producer Development, Z. C. Kline.
Surface Combustion (What is it?), C. E. Lucke.
Ore Dressing, Robert H. Richards.

NAVAL ARCHITECTURE AND MARINE ENGINEERING

SESSION 1.

Tuesday, Sept. 21, 10 a.m.

- Ship Calculation, Resistance and Propulsion, D. W. Taylor.
Ocean Freighters, Ernest H. Rigg.
Recent Developments in Japanese Shipbuilding, Dr. S. Terano.
Bulk Freight Vessels of the Great Lakes, Prof. Herbert C. Sadler.

SESSION 2.

Wednesday, Sept. 22, 10 a.m.

- River, Lake, Bay and Sound Steamers of the United States, Andrew Fletcher.
Special Types of Cargo Steamers for the United Coast to Coast Trade through the Panama Canal, George W. Dickie.
The Development of the Sail Yacht, Steam Yacht and Motor Yacht in American Waters, William Gardner.
The Lightship, G. C. Cook.

SESSION 3.

Wednesday, Sept. 22, 2 p.m.

- Warships of the First Line of Battle, Colonel E. Ferretti.
The Submarine, R. H. M. Robinson.
Present Condition of the Submarine, Max A. Laubent.
Modern Marine Gun Armament, H. F. Leary.
General Problem of Naval Warfare, D. W. Knox.

SESSION 4.

Thursday, Sept. 23, 10 a.m.

- Marine Boilers and Boiler Room Equipment, Charles F. Bailey.
The Development of the Marine Steam Turbine, H. C. Dinger.

The Application of the Steam Turbine to Marine Propulsion, J. F. Metten,
Recent Developments in Marine Engineering in Japan, Dr. M. Tsutsumi.

SESSION 5.

Thursday, Sept. 23, 10 a.m.

Coaling Plants and Floating Cranes of the Panama Canal, F. H. Cooke,
Cargo Handling Methods and Appliances, H. McL. Harding,
Some Economic Fundamentals of Freight Handling, David B. Rushmore,
The Modern Trend in American Marine Terminals, Robt. H. Rogers,
Cargo Handling Methods and Appliances, James A. Jackson.

SESSION 6.

Friday, Sept. 24, 10 a.m.

Fuel Oil, E. H. Peabody,
The Application of Diesel or Heavy Oil Engines to Marine Propulsion, G. C. Davison,
The Diesel Motor Applied to Marine Purposes, C. Kloos.

SESSION 7.

Friday, Sept. 24, 2 p.m.

Terminal Works, Dry Docks and Wharves of the Panama Canal, H. H. Rousseau,
Aids to Navigation of the Panama Canal, W. F. Beyer,
American Graving Dock Practice, Leonard M. Cox,
Dry Docks recently built in Italy, Prof. Luigi Luiggi.

MISCELLANEOUS

SESSION 1 (Aviation).

Wednesday, Sept. 22, 10 a.m.

Aeronautics, Dr. A. F. Zahm,
Arrival of the Aeroplane, A. E. Berriman,
A Discussion concerning the Theory of Sustentation and Expenditure of Power in Flight, F. W. Lanchester,
Principles and Theories of Aerodynamics, J. C. Hunsaker.

SESSION 2 (Refrigeration).

Thursday, Sept. 23, 10 a.m.

Refrigeration, J. F. Nickerson,
Refrigeration, Thor Andersson,
Refrigeration in France, L. Marchis.

SESSION 3 (Agricultural Engrg. and Engineering Education).

Friday, Sept. 24, 10 a.m.

Agriculture and the Engineer, J. B. Davidson,
Some Observations on the Extent and Value of Farm Power Equipment, Philip S. Rose,
Some Considerations Regarding Engineering Education in America, George F. Swain,
Technical Education for the Professions of Applied Science, Ira N. Hollis.

SESSION 4 (Heating and Ventilation).

Friday, Sept. 24, 2 p.m.

Introductory Paper, R. C. Carpenter,
Recent Developments in Heating and Ventilating Art, D. D. Kimball,
Vacuum, Vapour and Atmospheric Heating Systems, Jas. D. Hoffman,
Recent Developments in Ventilating Machinery, W. H. Carrier.

CLOSING GENERAL SESSION.

Saturday, Sept. 25, 11:30 a.m.

MEETINGS OF OTHER SOCIETIES

The American Society of Civil Engineers, the American Institute of Mining Engineers, and the American Institute of Electrical Engineers will also hold September meetings in San Francisco in the week preceding the International Engineering Congress. The headquarters of these societies and their places of meeting are listed below:

<i>Society</i>	<i>Headquarters</i>	<i>Meetings</i>	<i>Dates</i>
A. S. C. E.	St. Francis Hotel	at headquarters	Sept. 16-18
A. I. M. E.	Hotel Bellevue	at headquarters	Sept. 16-18
A. I. E. E.	St. Francis Hotel	{ Civil Center Auditorium }	Sept. 16-17

The meeting of the American Society of Civil Engineers is the Forty-seventh Annual Convention of the Society. The program includes a welcoming address by President Charles D. Marx; a Panama Canal session; a reception, dinner and dance in the Old Faithful Inn on the grounds of the Panama-Pacific International Exposition, and excursions to Del Monte, Santa Cruz and San José. The Society, through its Secretary, Chas. Warren Hunt, has extended a cordial invitation to the membership of our Society to participate in these events.

THE ENGINEERS' SPECIAL

In the July issue of The Journal reference was made to the "getting-together" arrangements for the engineers of the five national engineering societies that are to journey to San Francisco via the Engineers' special train on the New York Central, leaving New York 7:45 p.m., Thursday, September 9. A large party is scheduled for this train, the names of a considerable number of whom were listed in the July issue. Since that issue, several additional reservations have been made, and those among the membership who were not referred to in the previous list, are named below:

J. W. Upp
Henry Hess and Mrs. Hess
H. H. Barnes, Jr.
Gano Dunn
Emmett B. Carter and one
J. A. Seymour, Mrs. Seymour and Miss Seymour
William N. Best
Kenneth Seaver
E. L. Folsom and Mrs. Folsom
L. C. Marburg
Miss Kate Gleason.
H. M. Wilson and Mrs. Wilson
Charles Whiting Baker
S. Haar and party
Ralph E. Flanders
H. R. Cobleigh

PANAMA-CALIFORNIA EXPOSITION

The Exposition now being held at San Diego, California, is within easy reach of those visiting the Pacific Coast. This Exposition is also in commemoration of

the opening of the Panama Canal, but its theme is the exploitation of the possibilities and opportunities of the various sections of this coast, from Alaska to Peru.

The Exposition is staged in Balboa Park, in the heart of the city of San Diego, and its exhibits are grouped in an educational and attractive manner in twelve buildings.

PANAMA-PACIFIC INTERNATIONAL EXPOSITION

The interest of the visiting members will probably center in the Exposition and its many features of attraction. The points of particular interest to the members of the Society will be the Manufactures and Varied Interests Building; the Machinery Building; the Mines and Metallurgy Building, and the Education Building.

The great palace of Machinery is the largest on the Exposition site and is nearly a thousand feet in length. In this palace numerous groups comprising examples of steam generators and motors, internal combustion motors, hydraulic motors, and wood and metal working tools are shown.

The exhibits in the palace of Mines and Metallurgy deal with the natural mineral resources of the world, their conversion into metal and manufacture in raw materials and forms for the various industries.

Education is represented by examples including methods of vocational training and municipal training, in addition to general educational work of schools and universities.

The Manufactures and Varied Industries palace contains products of manufacture and manual skill from all nations of the world.

EXCURSIONS

For the benefit of members visiting San Francisco for the September meeting and the Congress, the following excursions to important engineering activities in California have been arranged. Some of these will be made by automobile without expense, and others will be at the cost of a round trip ticket.

September 18: San Francisco High Pressure Fire System.

Portrero Gas Works Electric Station A, Pacific Gas & Electric Co.

Spring Valley Water Works.

September 19: Delta Lands of the Sacramento and San Joaquin Rivers.

Spring Valley Water Works.

September 17 to 18: Great Western Power Company's Hydroelectric development on the Feather River.

Gold dredging at Oroville.

September 18 to 19: Pacific Gas & Electric Co.'s Hydroelectric development at Lake Spaulding and Drum Power House.

North Star & Empire Mines at Grass Valley.

September 17 to 19: Oil fields at Coalinga.

THE RETURN TRIP

Members of the party that go to San Francisco by the Engineers' Special have the privilege of returning by any one of several routes, which are given below. Rates for any of these routes will be gladly quoted by Mr. Harner, the New York Central Lines agent.

Via Southern Pacific or Western Pacific to Ogden and Salt Lake City, over the Rocky Mountains to Denver or Cheyenne, thence via Chicago or St. Louis.

Via Los Angeles, San Pedro Route to Salt Lake City, and thence as above.

Via Los Angeles, the Santa Fé Route through Albuquerque (also to Denver if desired) to Chicago.

Via Los Angeles, El Paso and the Rock Island Route to Chicago.

Via Los Angeles and El Paso to New Orleans, thence via St. Louis, Chicago or Cincinnati.

Via Portland, Tacoma, or Seattle, thence via Ogden and Salt Lake City and the Rocky Mountains to Cheyenne or Denver, and Chicago or St. Louis.

Via Portland, Tacoma and Seattle to St. Paul, thence via Chicago.

Via Portland and Tacoma to Seattle, steamer or rail to Vancouver, thence via the Canadian Rockies, Winnipeg and St. Paul to Chicago.

VOLUME 36 OF TRANSACTIONS

The annual volume of Transactions for 1914 has been distributed to the membership during the past month. This volume, like the previous ones, contains the papers and discussion given at the Annual and Spring meetings, in this case the Spring meeting at St. Paul-Minneapolis, together with reports of committees.

At the St. Paul-Minneapolis meeting there was given besides the miscellaneous papers, the symposium on powdered fuel, which is included in the volume; and among the miscellaneous papers were three contributed by local engineers on coal handling methods on the Great Lakes, flour milling and the hydraulic power development on the Mississippi River.

At the annual meeting there was a symposium on Locomotives of To-day, covering features of design and the results of operation of modern locomotives. There was also an all day meeting under the direction of the Public Relations Committee at which nine papers were presented on the general topic of the engineer in public service.

It is noteworthy that of the 45 papers and reports included in the volume, no less than 23 were prepared through the efforts of committees of experts in their respective fields, by which the authoritative character of the contributions is appreciably enhanced. There are 145 individual contributors, besides those who collaborated in the preparation of the several reports.

It was possible to include in this number of Transactions the report of the Boiler Code Committee in its

revised form, an early draft of which was sent to each member last November. This report is the most extensive, and will probably be the most far-reaching in its results, of any single undertaking by the Society up to the present time. Four states and one city have already adopted its provisions.

The variety of the papers presented and the wide scope of their contents is indicated by the following classified list of topics which were covered by the papers and discussion at the Annual and Spring meetings for 1914 and which are included in this volume:

SUBJECT CLASSIFICATIONS

Abrasives.	Factory buildings.
Air compressor unloaders.	Feed water heaters.
Appraisals.	Filters.
Ash fusion temperatures.	Fireproof construction.
Biography.	Flanged fittings.
Bonus payments.	Floors.
Cast iron pipes.	Flour milling.
Cement kilns.	Friction losses.
Clinkering of coal.	Fuel.
Coal classification.	Furnaces.
Crane wheels.	Fusion temperatures.
Damage cases.	Gear testing machines.
Dams.	Grinding wheels.
Economic problems.	Hardening steel.
Efficiency.	Heating boilers.
Electric drives.	Heating value of fuels.
Electric lighting plants.	Hooke's joint.
Engineering training.	Hydroelectric development.
Ethics.	Industrial service work.

Ingot.
Locomotives.
Materials of construction.
Meetings.
Methane.
Milling machines.
Municipal engineering.
Natural gas.
Necrology.
Police arm.
Powdered fuel.
Power plant auxiliaries.
Publicity.
Railroad equipment.
Railroad scales.
Recorders.
Reinforced concrete.
Sewage disposal.

Snow removal.
Society affairs.
Specifications.
Standardization.
Steam boilers.
Steel rails.
Stokers.
Storage of fuel.
Superheaters.
Symbols.
Testing meters.
Time studies.
Tool steel.
Transportation of fuel.
Universal joint.
Water meters.
Water power.
Weighing scales.

THE USE OF MEMBERSHIP CARDS

The membership is warned to be on guard against persons representing themselves as members of the Society. Complaints continue to be received that men posing as members are attempting to borrow money.

Membership requirements were never so strict as they are to-day, and you will protect the Society as well as yourself by requiring a stranger announcing himself a member to show the introductory card. Every member of the Society in good standing receives a card of introduction every year with the date clearly shown.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON OCTOBER 10, 1915

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their ages would qualify them and not with regard to professional qualifications, i. e., the ages of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of grading are also posted.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

ALMEIDA, MANUEL G. ROSADO, Sales Engr., De La Vergue Mch. Co., Merida, Yucatan, Mexico
BAKER, NORMAN L., Mech. Engr., By-Products Coke Corp., Chicago, Ill.
BAKER, WM. H., Asst. Genl. Supt., The Atlas Portland Cement Co., Hannibal, Mo.
BALOUGH, CHARLES, Cons. Engr., Springfield, Ohio
BARNES, WALTER E., Vice-Pres., Consolidated Engrg. Co., Boston, Mass.
BEAKEY, PATRICK J., Foreman Type Dept., Royal Typewriter Co., Inc., Hartford, Conn.
BEAUMEN, JAMES A., Mech. Engr., Weber Subterranean Pump Co., New York, N. Y.

The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential, and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received by October 10, 1915.

BERGMAN, CARL AXEL, Palmarito de Cauto, Oriente, Cuba
BLACK, ALEXANDER L., Engr. in charge of design and construction, New Orleans Office, Ford, Bacon & Davis, New Orleans, La.
BOYD, JAMES E., Prof. of Mechanics, Ohio State Univ., Columbus, Ohio
BOYLE, WM. GEO., Mech. Supt. & Engr., Estate of Henry W. Oliver, Pittsburgh, Pa.
BREWSTER, HENRY B., Engr., with H. S. Kerbaugh, Inc., New York, N. Y.
BRUNNER, GEO. L., Treas. & Genl. Mgr., Brunner Mfg. Co., Utica, N. Y.
BRYAN, ARTIS CHESTER, Chief Engr. & Factory Mgr., Lefever Arms Co., Syracuse, N. Y.
CHACE, ERNEST M., Wks. Mgr., The Cincinnati Milling Mch. Co., Cincinnati, Ohio

- CHARLES, LA VERN JOHN, Civil Engr., Constr. Engr., U. S. Reclamation Service, Elephant Butte, New Mexico
- CLARK, HENRY D., with Alloy Steel Spring Co., Jackson, Mich.
- COLLINS, THOMAS A., Mech. Engr., Mt. Vernon Car Mfg. Co., Mt. Vernon, Ill.
- CUNNINGHAM, GEORGE F., Owner, Cunningham Construction Co., Blissville, Ark.
- DOYLE, EDMUND M., Mgr., Doyle Estate Co., San Francisco, Cal.
- ELY, HAROLD F., Mech. Draftsman, Alberget Pump & Condenser Co., New York, N. Y.
- ENGLERT, ALFRED, Mech. Engr., Lidgerwood Mfg. Co., New York, N. Y.
- FITTS, EDWIN, Engr., Detroit Stoker Co., Detroit, Mich.
- FORNEY, J. RAYMOND, Southern Rep., Ralston Steel Car Co. of Columbus, Baltimore, Md.
- GHERARDI, RANCROFT, Engr. of Plant, American Telephone & Telegraph Co., New York, N. Y.
- GINORIO, FRANCISCO R., Elec. Engr., Cuban-American Sugar Co., Central Delicias, Oriente, Cuba
- GRANGER, ABBOTT DEAN, Pres., A. D. Granger Co., New York, N. Y.
- GRATIER, LESLIE V., Dist. M.P. Insptr., Pittsburgh Dist. & Chicago Div., Baltimore & Ohio Railroad, Pittsburgh, Pa.
- GUIGNARD, C. G., Columbia, S. C.
- HADLEY, SAMUEL L., Asst. Dir. of Sales, Fairbanks, Morse & Co., Chicago, Ill.
- HALL, ROLAND B., JR., Mgr. New York Office, Harrisburg Fdry. & Mch. Co., New York, N. Y.
- HENDERSON, MALCOLM MCG., Chief Mech. Engr., Australian Commonwealth Rwy., Melbourne, Australia.
- HENNING, WARREN K., Sales Engr., Murphy Iron Works, Chicago, Ill.
- HICKS, WM. A. B., Chief Draftsman, I. P. Morris Co., Philadelphia, Pa.
- HITCHCOCK, HARRY S., Treas., Baker Iron Works, Los Angeles, Cal.
- HOBART, HENRY M., Cons. Engr., General Elec. Co., Schenectady, N. Y.
- HOWES, BENJAMIN A., Engineer in private practice, New York, N. Y.
- HOXIE, V. W., Marine Dept., The Babcock & Wilcox Co., Pacific Coast Branch, San Francisco, Cal.
- HUFF, RUSSELL, Cons. Engr., Packard Motor Car Co., Detroit, Mich.
- JELLET, STEWART A., Cons. and Constr. Engr., Philadelphia, Pa.
- JOHNSON, GEORGE A., Mech. Supt., with W. H. Miner, Chicago, Ill.
- JONES, HAROLD C., Asst. to Vice-Pres., Inland Steel Co., Chicago, Ill.
- KLEIN, BERNARD J., Exhibit Mgr., The Bristol Co. of Waterbury, Conn., Palace of Machinery, San Francisco, Cal.
- LANGILLE, HERBERT B., Asst. Prof. Mech. Design and Mech. Drawing, Univ. of Cal., Berkeley, Cal.
- LARKIN, FRED V., Asst. Prof. Mech. Engrg., Lehigh Univ., So. Bethlehem, Pa.
- LEHMAN, WERNER, Mech. Engr., Bucyrus Co., South Milwaukee, Wis.
- LEWIS, E. J., Supt., Climax Mfg. Co., Corry, Pa.
- LEWIS, GEORGE WM., Asst. Prof. Mech. Engrg. in charge of Exper. Engrg., Swarthmore College, Swarthmore, Pa.
- LEWIS, WARREN B., Cons. Engr., Providence, R. I.
- LECHTNER, WILLIAM O., Cons. Engr., Newton Highlands, Mass.
- LOOSE, THERON L., Genl. Supt., Hendee Mfg. Co., Springfield, Mass.
- LYSTER, T. L. B., Chief Engr., Hooker Electrochemical Co., Niagara Falls, N. Y.
- MACLEOD, NORMAN MACCALLUM, Lab. Elec. Engr., Western Electric Co., New York, N. Y.
- MAAS, ELOF F., Chief Draftsman Machinery Div., Navy Yard, Puget Sound, Wash.
- MANCHESTER, HENRY C., Supt. of Motive Pwr. & Equip., Delaware, Lackawanna & Western R.R., Scranton, Pa.
- MATHEY, HENRY C., Asst. Engr., Underwriters' Laboratories, Inc., New York, N. Y.
- METTEN, JOHN F., Chief Engr., Wm. Cramp & Sons Ship & Eng. Bldg. Co., Philadelphia, Pa.
- MORSS, HENRY A., Vice-Pres., Simplex Wire & Cable Co., also The Morss & Whyte Co., Boston, Mass.
- NOBLE, HOWARD A., Vice-Pres., Pittsburgh Spring & Steel Co., Pittsburgh, Pa.
- PACKER, E. RAY, Mech. Engr., The Q & C Co., Chicago, Ill.
- PAFFEN, PAUL J., Engr., Barrett Mfg. Co., New York, N. Y.
- PARCE, JOSEPH VALE, Director Shop Work, Manual Training High School, Denver, Colo.
- PROUTT, FREDERICK G., Cons. Engr., Memphis, Tenn.
- RUSS, JOHN B., Mech. Supvr., The Robert N. Bassett Co., Derby, Conn.
- SANDERS, W. E., Mgr. Packing Dept., Essex Rubber Co., Trenton, N. J.
- SHAW, WM. M., Vice-Pres. & Genl. Mgr., The Benj. F. Shaw Co., Wilmington, Del.
- SMITH, ALBERT H., Production Engr., Sefton Mfg. Co., Chicago, Ill.
- SMITH, JAMES C., Supt., McNab & Harlin Mfg. Co., Paterson, N. J.
- STREIFF, ABRAHAM, Hyd. Engr., Fargo Engrg. Co., Jackson, Mich.
- TOMPKINS, GEORGE R., Head of Mech. Dept., Wilberforce Univ., Wilberforce, Ohio
- VOCKE, CHAS. WM., Developing patent claims, Ridgewood, N. J.
- WAIL, HENRY R., Mech. Engr., Commonwealth Edison Co., Chicago, Ill.
- WALKER, F. W., JR., Genl. Mgr., Beaver Falls Art Tile Co., Beaver Falls, Pa.
- WATKINS, EDWARD G., In charge Engrg. Dept., Heywood Bros. & Waketield Co., Gardner, Mass.
- WHITE, HAROLD E., Controller Engr., Crocker-Wheeler Co., Ampere, N. J.
- WILLIAMS, ARTHUR, Genl. Commercial Mgr., The New York Edison Co., New York, N. Y.
- WOODARD, WM. E., Asst. Chief Engr., Amer. Loco. Co., Schenectady, N. Y.

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

- ABBE, ROY H., Mech. Engr., Towle Mfg. Co., Newburyport, Mass.
- ADAIR, CRAIG, Mech. Engr., The Baldt Steel Co., New Castle, Del.

AIREY, JOHN, Asst. Prof. of Engrg. Mechanics, Univ. of Mich., Ann Arbor, Mich.

BRONSON, CARLOS E., Asst. Mech. Engr., Kewanee Boiler Co., Kewanee, Ill.

BUCKLEY, AMBROSE T., Electrician, Dept. of Public Charities, Staten Island, N. Y.

COBB, HOWARD P., Industrial Engr., D. B. Lewis & Co., Boston, Mass.

CURTISS, CHARLES B., with The Wickes Boiler Co., Saginaw, Mich.

DANIELS, CLARENCE W., Plants Engr., Norton Co., Worcester, Mass.

FRENCH, CHARLES M., Sales Engr., Wagner Elec. Mfg. Co., Springfield, Mass.

GRAVES, RALPH L., Mech. Asst. to Genl. Pur. Agt., Chicago & North Western Rwy. Co., Chicago, Ill.

GRIENERT, ARTHUR E., Asst. Efficiency Engr., Commonwealth Edison Co., Chicago, Ill.

HENSEL, ALBERT G., Denver, Colo.

HEYWARD, THEODORE C., Asst. to Thomas B. Whitted, Charlotte, N. C.

NOEISE, CHESTER LINWOOD, Mech. Engr., The Fiberloid Co., Indian Orchard, Mass.

PEW, JOSEPH N., JR., Vice-Pres., Sun Co., Philadelphia, Pa.

PULLEN, ROYAL R., Mech. Engr., The Canadian Klondyke Mining Co., Ltd., Dawson, Y. T., Canada

REED, HARRY A., Resident Engr., Stone & Webster Engrg. Corp., Boston, Mass.

REEDS, CLARENCE, Cons. Engr. with John A. Stevens, Lowell, Mass.

SEES, JOSEPH FRANK, Asst. Chief, Equip. Engrg. Div., Union Metallic Cartridge Co., Bridgeport, Conn.

THOMPSON, PAUL W., Tech. Engr., The Edison Ill. Co., Detroit, Mich.

WING, STEPHEN R., Prof. Mech. & Elec. Engrg., Pennsylvania College, Gettysburg, Pa.

FOR CONSIDERATION AS JUNIOR

BLANK, BERNARD, Elec. Designer, Pennsylvania Railroad, West Jersey & Seashore Div., Camden, N. J.

BURLEY, E. R., JR., Asst. Engr., Old Reliable Motor Truck Co., Chicago, Ill.

DEDICKE, CARL E., Engr., The Felters Co., Inc., Middleville, N. Y.

DICKEY, RALPH L., Planning Clerk, Warren Power Sta., N. Y., N. H. & H. R. R., Warren, R. I.

ENDICOTT, GEORGE, with The Morgan Spring Co., Worcester, Mass.

FOLLMER, CLINTON L., Mech. Engr., The Consolidation Coal Co., Inc., Fairmont, W. Va.

FRANKLIN, PAUL A., Supt. of Newark Warehouse, American Sanitary Wks., Harrison, N. J.

GUILFORD, EDWARD F., Asst. Supt. of Dial Dept., Hamilton Watch Co., Lancaster, Pa.

HOWE, JACK L., Estimator & Salesman, Otis Elev. Co., San Francisco, Cal.

HOYT, FRANK W., Engr., Winchester Repeating Arms Co., New Haven, Conn.

LAUER, CARLETON J., Tiffin, Ohio

MACKENZIE, G. EARL, Research Dept., Western Elec. Co., New York, N. Y.

MAY, HOWELL B., Special Apprentice with American Steel Foundries, Alliance, Ohio

NEIL, EDMUND B., Personal Asst. to Chief Eng., Truck Dept., Pierce-Arrow Motor Car Co., Buffalo, N. Y.

NORRIS, J. BOYD, JR., Oiler with The Coastwise Transportation Co., Boston, Mass.

PARSELL, ROY LINWOOD, with Winchester Repeating Arms Co., New Haven, Conn.

REYNOLDS, JAMES J., Genl. Supt., Thurlow Steel Works, Inc., Chester, Pa.

SCHAEFER, WALTER A., Underwriter with Workmen's Compensation Insurance & Ocean Accident & Guar. Corp., Ltd., New York, N. Y.

SCRANNAGE, LAWRENCE E., Asst. in Planning Dept., Remington Arms & Ammunition Co., Bridgeport, Conn.

SHORT, FRANK, Inst. in Elec. Engrg., Univ. of Pennsylvania, Philadelphia, Pa.

STARK, WILLET E., Engr., The B. F. Sturtevant Co., Hyde Park, Mass.

STRADER, ROLAND HAROLD, JR., Asst. to Supt., Standard Gas Light Co., New York, N. Y.

STURMEFELS, GEORGE J., JR., Draftsman, Maryland Steel Co., Sparrows Point, Md.

VOORHEES, ALBERT C., Head of Tech. Dept., Lake Torpedo Boat Co., West Coast Branch, Long Beach, Cal.

WEISS, HERBERT A., Asst. Prof. in Drawing, Georgia School of Tech., Atlanta, Ga.

WILTON, HUGH, Dir. of Mech. Shop Practice & Trade, State Trade School, Putnam, Conn.

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

BASS, W. J., WILLARD J., Engr., Armour & Co., Chicago, Ill.

THOMPSON, O. C., Mech. Engr., Wirebounds Corp., Chicago, Ill.

PROMOTION FROM ASSOCIATE-MEMBER

MISOSTOW, HENRY, Mech. Engr., Smoke Dept., City of Chicago, Chicago, Ill.

WRIGHT, PAUL, with American Cast Iron Pipe Co., Birmingham, Ala.

PROMOTION FROM JUNIOR

BLUMENFELD, RALPH, Asst. Mech. Engr., Keller Mech. Engr. Co., Brooklyn, N. Y.

BRAMAN, SAMUEL N., with The Morss & Whyte Co., Boston, Mass.

NEW APPLICATIONS FOR LISTING IN THE 1916 YEAR BOOK

Applications should be filed by September 27, in order that those elected may qualify in time to be included in the list of members appearing in the 1916 issue of the year book.

THE CONNORS CREEK PLANT OF THE DETROIT EDISON COMPANY

BY C. F. HIRSHFELD, DETROIT, MICH.

Member of the Society

THE phenomenal growth of Detroit's population and industries has been widely heralded, but it is probable that the extent of this growth and its significance to the central station industry is not appreciated by those not closely in touch therewith. For this reason the curves in Fig. 1 are shown. The upper curve, showing the variation of population during the past decade, is probably approximately correct, because it fits smoothly into the curve obtained by plotting United States Census figures and because it checks very closely with the more accurate of the estimates which have been made from time to time. This curve indicates that the population of Detroit in 1914 was about 1.6 times as great as it was in 1904, just ten years before.

The annual output of the central stations, as given by the next lower full-line curve, has increased much more rapidly than the population. In the year 1914 it was about 21.4 times as great as in 1904. The fact that the maximum annual peak was only ten times as great in 1914 as in 1904 indicates that a very large part of the increased annual output was due to increased industrial application. This is also partly indicated by the curve showing variation of load factor.

A map of the City of Detroit is given in Fig. 2. The heavy full lines radiating, roughly, from a point near the bottom center of the figure indicate radial streets upon which the principal car lines are operated. These naturally determine the directions of growth and they indicate that, other things equal, Detroit's area may be expected to preserve a roughly semicircular shape as it expands. The heavy dotted lines indicate the rights of way of the various steam railroads entering the city. Other things equal, these rights of way, combined with the river frontage, indicate the probable future locations of the larger manufacturing industries. Apparently, these industries may be expected to scatter all along these lines in the future, as they have in the past.

The small rectangular spots indicate the locations of the various substations of the Detroit Edison Company. These are so drawn that the length of a side indicates the relative capacity. The concentration near the center from which the radial streets diverge is due to the fact that this is the business center of the city and that it is served with direct current. This gives a very concentrated and very important direct current load at this point.

The two circular spots near the lower left hand corner of the figure indicate the location of Delray power houses No. 1 and No. 2. These have an aggregate maximum capacity of about 95,000 kw. and contained practically all the generating equipment of the company before the Connors Creek plant was built. They are adjacent to one another and operated as one plant.

When it became evident about 1912 that greatly increased capacity would soon be required, two possible solutions were available; a third power house could have been built at the

Delray site or a new site could have been selected. Consideration of the direction of growth of the city; the rapidly increasing population and industrial development of the east side; the location of the heavy direct current load; necessity for continuity of service with an ever increasing complexity of distribution system fed from one point near what might be called a corner of the city; and numerous similar items resulted in the choice of a new site, despite the many duplications which such a choice involved. The transmission loss in underground cables of a mean length of seven miles required to serve the growing east side manufacturing

FIG. 1 CURVES INDICATING GROWTH OF CITY AND LOAD

district and the fixed charges on these cables and their conduits were, by themselves, almost adequate to determine the choice.

The site chosen is indicated by the circular dot near the lower right hand corner of Fig. 2. Being on the river front, excellent condensing water is available in enormous quantities. In this respect, it is even better situated than the older site at Delray, as the river flows from the newer toward the older site and picks up all the sewage of the city while passing the water front. Being at the river end of a terminal railroad, the new site can be supplied with coal as easily as the old site, and if water transportation of coal should become profitable, both sites are equally well located to avail thereof.

Considering the distribution problems, the new site may be said to be strategically located as a combination with the older site at Delray. A glance at the map and a study of the radiating streets and of the railroads, will show this very clearly.

The Connors Creek site is large enough to accommodate two power houses, each with greater capacity than that of the two power houses at Delray combined. The first house was planned to accommodate six 25,000 k.v.a. units, but it seems probable that this unit size will be increased before the last

units are installed. The plan of this house is shown in Fig. 3, together with the canals and tracks which serve it. The river is located beyond the left-hand side of the figure and runs in a direction roughly parallel to the left-hand end of the plate, and upward. The diagonal position of the plant was dictated by the shape of the site, the necessity of leaving room for a future power house, the curves required for railroad tracks, and the location of the river which determined the direction and location of the canals. One-third of the first power house on the Connors Creek site has been built and two of the proposed six units are installed. The build-

capacity. This crusher breaks from 18-in. cubes, or smaller, to 100 per cent through a $1\frac{3}{4}$ -in. ring.

The crusher discharges directly into a motor-driven, constant-speed, lapping bucket conveyor with 30 by 36 in. buckets. This conveyor forms an endless chain which entirely encloses the section of the boiler house, as indicated in Fig. 5. It carries the coal up on the side nearest the coal shed and discharges it into any one of the three coal bunkers which serve the two boilers of one unit. The hopper, pan conveyors, crusher and bucket conveyor for each unit of one turbine and two boilers are so located that they can deliver

FIG. 2 MAP OF THE CITY OF DETROIT SHOWING LOCATION OF PLANTS

ing is closed with a temporary end, so that the machinery now installed can be operated until and while future extensions are being constructed. The intake and overflow canals are completed in full size for six units.

An architect's drawing of the finished power house is given in Fig. 4 and a sectional elevation in Fig. 5. The latter shows the construction to best advantage and should be consulted in connection with the description which follows.

The coal enters the train shed in drop-bottom cars (usually of the 50-ton size) which move on the lower group of tracks shown in Fig. 3 after being weighed on the railway scales indicated near the upper left-hand corner of that figure. The cars dump into hoppers under the tracks in the train or coal shed, there being one hopper for each unit of one turbine and two boilers. A motor-driven, variable-speed, flight conveyor with a capacity of 120 tons per hour, receives the coal from the hopper, carries it up a rather sharp incline and discharges it into a four-roll motor-driven crusher of similar

through chutes to one adjacent range of bunkers, serving thus as a spare for that range.

The entire coal handling equipment is electrically operated and the control is centralized at a board in the coal crushing room. Starting devices are electrically interlocked so that the various pieces of apparatus must start in proper sequence. Provision is also made to prevent starting until an observer on the floor above the coal bunkers has determined that the exposed upper horizontal run of the bucket conveyor is clear, and has so indicated. Emergency buttons are provided at numerous points along the run of the bucket conveyor; pushing any one of these stops the entire system and it cannot be started again until that particular emergency button has been reset by means of a key. The custodian of this key is therefore the only individual who can start the system after an emergency stop, and even then he must go to the point from which the stop was made.

After the coal has been dropped into the bunkers, it de-

sends by gravity to the stokers. The latter are of the underfeed, sloping fire-hed variety and there are twenty-six retorts per boiler. These are arranged in two groups of thirteen each, the boiler being fired from the two ends, as shown in Fig. 6. Ash and clinkers are removed by two elinker grinder bars located in a sort of pit running across the center of the furnace and are discharged into the ash hopper. This is an enclosure within the wind box or plenum chamber below the boiler and holds the refuse until it is finally dropped directly

of air per minute against a static pressure of 6.5 in. of water pressure. The motors are shunt wound and are direct connected to the blowers through flexible couplings. Their speed can be varied from 300 to 750 r.p.m. The drum type controllers are mounted at the gauge boards of the boilers served, directly under gauges which indicate the static pressure in the plenum chamber.

The boilers are similar to those used in the older plant at Debray, but are set 3 ft. higher so that the height of the com-

combustion chamber is 33 ft. These boilers each have 23,654 sq. ft. of water heating surface and are built to operate at 225 lb. per sq. in. The superheaters have about 2400 ft. of surface and are designed to give 200 deg. Fahr. superheat at 200 per cent of rating.

The gases, leaving the dampers at the top of the boiler setting, pass upward through easily curved breechings, into the steel stack near its base. This stack is supported entirely on the steel work of the boiler room structure and extends to a height of 325 ft. above the floor on which the stokers are located. It has a height of about

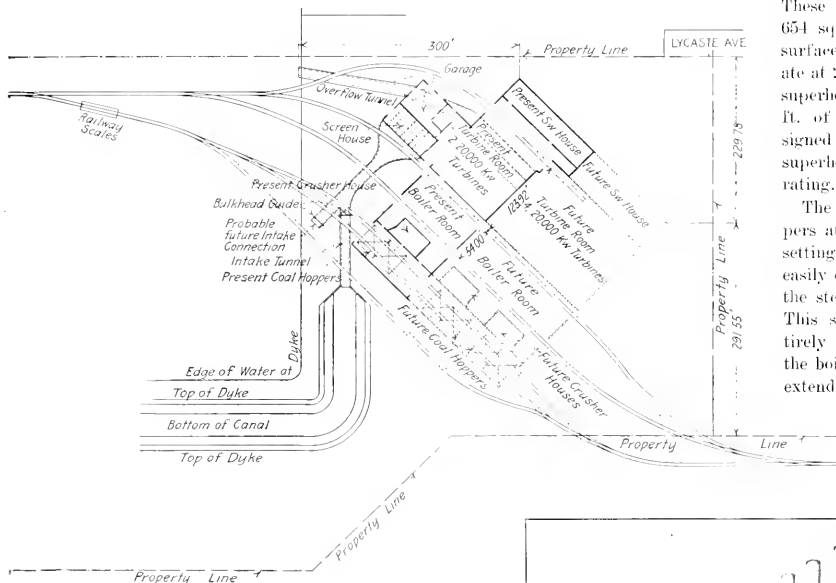

FIG. 3. PLAN OF SITE OF THE NEW POWER HOUSE

into standard railroad cars which run lengthwise of the house directly under the ash hoppers.

The stokers are driven through chains by direct current motors, the speed of which can be varied from 200 to 2000 r.p.m. This wide range of speed is obtained by means of armature throw over from 125 to 250 volts combined with field control. The motors are handled by means of drum controllers located at the gauge board of the particular boiler which they serve and electric tachometers are used to indicate stoker speeds at this board.

Motor driven blowers supply the air required for combustion. There are three of these blowers per range of two boilers. One of the three serves as a spare and is located between the two boilers. It is arranged to discharge either way through a Y-shaped duct. All of the blowers discharge through expanding ducts which are designed to recover the greatest possible fraction of the velocity head. These large ducts lead into a plenum chamber with a horizontal section equal to the horizontal section of the furnace. The stoker wind boxes form part of the roof of this chamber, so that the air passes directly from the plenum chamber to the stoker and does not have to pass through small ducts of any kind. Each blower is designed to deliver at maximum 74,000 cu. ft.

A black and white photograph of a large, multi-story industrial building, likely a power plant or factory. The building has a long, rectangular structure with multiple windows and a flat roof. Several tall, slender smokestacks rise from the roofline, extending into the sky. The foreground shows a flat, open area, possibly a parking lot or a cleared field, with some small, dark patches that might be trees or shrubs. The overall scene is industrial and somewhat desolate.

FIG. 4 VIEW OF THE PROJECTED CONNORS CREEK POWER HOUSE

240 ft. above the roof of the boiler house. The stack is brick lined and has a diameter of 16 ft. inside the lining.

As already mentioned, there are only two boilers per turbine. When operating the turbine at full load, the boilers will operate at about 170 per cent of Centennial rating. In the ordinary sense, there are no spare boilers. Experience has shown, however, that these boilers can be safely and

economically operated at ratings considerably in excess of 170 per cent and provision has been made to enable three boilers to supply steam to two turbine units. When carrying full turbine loading under these conditions, each of the three boilers will have to operate at about 225 per cent of rating.

The main live steam piping consists of a run from two boilers to the unit which they serve, all of these runs being cross connected by a cross-over header. All of this piping is located in the so-called pipe gallery below the stoker floor, except, of course, the leads dropping down from the boilers and rising to the turbine throttles.

The steam leads from each boiler are of 10 in. pipe and these join together in a Y-fitting, which has a 14 in. discharge. Under full load conditions with two boilers supplying one unit, the steam velocities will be about 10,500 ft. per min. in the 10 in. pipe and 12,000 ft. per min. in the 14 in. pipe. With three boilers supplying two units, these velocities will rise to about 14,000 and 16,000 ft. per min., respectively.

The proposed use of the cross-over main necessitated a design which should permit steam from any two boilers to flow into that main, and steam from the main to flow into any turbine lead, with practically equal facility. After many designs had been considered, that shown in Fig. 7 was adopted. The steam leaving the 10 x 14 x 10 in. Y-branch previously mentioned, passes through a cast steel expanding nozzle which enlarges to a diameter of 28 inches. This, in turn, leads into a 28 in. cast steel side-outlet T or side-outlet cross. The 28 in. lateral outlets of the latter fittings are the connection points of the cross-over main. The velocity of the steam passing into the cross-over, or from the cross-over main to the turbine lead, is thus reduced to about one-quarter of its value in the 14 in. pipes, or roughly, a little less than 4000 ft. per min. under the worst conditions. The steam turns through the necessary right angle at this low velocity and therefore with small loss.

Steam leaving the 28 in. fitting on its way to the turbine is carried through a tapered reducer with a discharge diameter of 14 in. Similarly, steam leaving the 28 in. fitting on its way to the cross-over main passes through a tapered reducer which is cast with its longitudinal axis in the shape of a quarter circle. This reducer leads the steam into a 14 in. return bend, as shown in Fig. 7.

The steam for the auxiliary turbines, which will be mentioned later, is taken from a six inch outlet on top of the 28 in. fittings above described.

All superheated steam piping is full weight steel with welded flanges. The flanges are finished smooth and corrugated steel gaskets are used. All fittings are cast steel. At the Delray plant, Hopkinson-Ferranti valves with Venturi throats were used; these have been found to cause an excessive pressure drop because of the short length of the expanding nozzle and were therefore not deemed desirable for the new plant if an equally reliable, full opening form could be found. Full throated gate valves made by Hopkinson of the same material as the Ferranti valves were therefore used in the Connors Creek plant.

The atmospheric exhaust from the main unit is made of riveted steel pipe and fittings. The auxiliary exhaust piping is lap welded steel with Van Stone joints and fitted with corrugated copper gaskets. All valves in the exhaust lines are steel gate valves of American make. All saturated

steam piping is extra heavy steel fitted with steel flanges. The fittings are all cast steel and steel valves of American make are used.

The feed water piping is extra heavy, lap welded steel, with Van Stone joints and cast steel fittings. The use of steel pipe throughout for the feed water represents a marked departure from Delray practice in which brass pipe was used for the boiler leads and connections. In laying out the feed water system at Connors Creek, the design was so ar-

FIG. 6 DETAILS OF THE LARGE BOILERS

ranged as to permit of free expansion without the use of expansion joints of any kind.

The boiler blow-off valves are also made by Hopkinson. These were decided on after two of them had been in satisfactory operation for several years at Delray. The valve is a parallel-seat gate, on whose stem is cut a rack which meshes with a pinion. A 180 deg. turn of the handle turns this pinion through a like angle and fully opens the gate. The superiority of the valve appears to be due to the use of excellent metal and to a very high class of machine work.

The main units, as previously mentioned, are rated at 25,000 k.v.a. or 20,000 kw. at 80 per cent power factor. The steam end consists of a horizontal, nine stage, 1200 r.p.m. turbine; the electrical end generates three phase, sixty cycle current at 4800 volts. A section of the turbo-generator unit is shown in Fig. 8. The steam exhausted from the turbine

passes down through a large expanding exhaust nozzle into the condenser, as shown in Fig. 5. Each condenser is built to contain 35,000 sq. ft. of heating surface made up of 1 in. tubes a little over 18 ft. long, but has only 32,500 sq. ft. installed. The tube heads have a diameter of 14 ft. 6 in.

The tubes are so arranged as to leave numerous lanes through the steam space, so that the vapor and air readily flow to all parts of the cooling surface. No baffles of any kind are used, excepting only those necessary to form an air box. The latter is located at the bottom of the condenser, as indicated in Fig. 9.

The condensate collects in a cylindrical hot-well which extends from the lower part of the condenser shell, and it is

cut shown in the plan in Fig. 3 and thence flows through a concrete tunnel to the screen house. This tunnel has a free section 9 ft. 3 in. high by 10 ft. wide, and when it is supplying water for all of the units in the finished plant under the lowest water conditions on record, the water velocity will be just under 8 ft. per second; in obtaining this, further units are assumed to be larger than those now installed.

The water flows from this section of the tunnel into a sort of funnel-shaped enlargement which leads it to the screens. These are of the traveling variety and are similar to screens already installed in the Northwest Station in Chicago and at the Delray Station in Detroit. They consist of woven-wire panels fastened to the links of an endless chain,

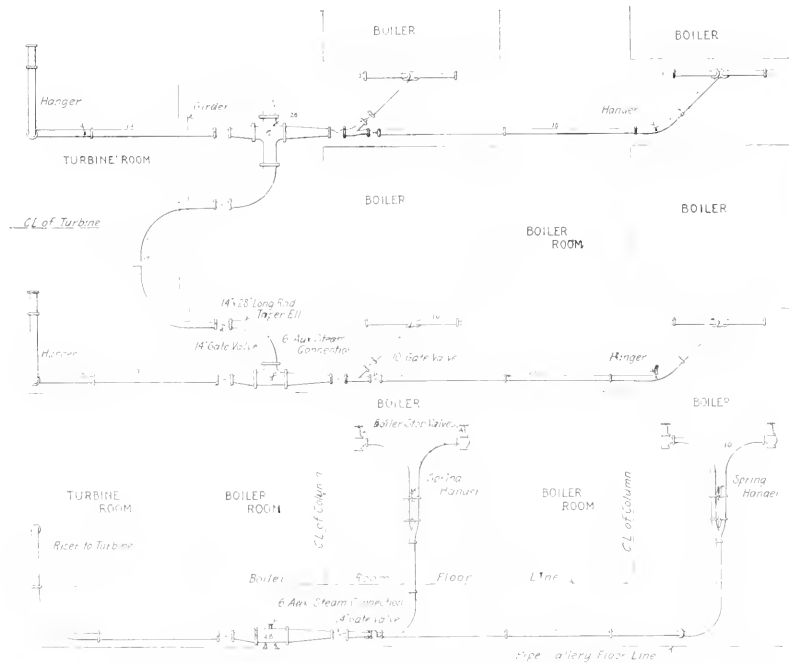

FIG. 7 DETAILS OF THE HIGH PRESSURE STEAM PIPING SYSTEM

removed by either one of two hot-well pumps. These are motor-driven two-stage centrifugal pumps operated at 1200 r.p.m. and they are fitted with bronze impellers. The condensate is discharged into what is known as the cold end of the boiler feed tank, as will be explained later.

Circulating water is supplied to each condenser by a motor-driven single-impeller double-suction, volute pump. The motor is three-phase, slip-ring type arranged for a 15 per cent speed variation, the maximum speed being 400 r.p.m. During the period of the year when the circulating water has a high temperature, the pump will be operated at the highest speed and will deliver about 40,000 gal. per min. When the water temperature is low, the pump will be operated at the lower speed and the quantity will be proportionately reduced. The temperature of circulating water varies with the season from 34 deg. to 76 deg. fahr.

The circulating water enters the property through an open

the lower end of the loop thus formed projecting down to the bottom of the water channel. The construction is shown in Fig. 10, which is a reproduction of a photograph taken in the interior of the screen house before it was completed.

When a screen becomes fouled, the working side of the loop is drawn up and over the upper guide shaft, its place being taken by what was previously the back side of the loop. This operation brings the fouled screen panels under a wash pipe which washes the fouling material into a channel arranged to carry it to the overflow canal. The screens are operated by motors and are started and stopped periodically as required. Their constant movement is only necessary under exceptional conditions. Provision is made for returning water from the overflow tunnel into the intake to assist in keeping screens and tunnel clear of ice during cold weather.

After passing through the screens, the circulating water

is turned through a right angle and flows down the length of the house in a tunnel which is 15 ft. wide and 9 ft. 3 in. high. Water is picked up by the circulating pumps through large angle fittings encased in the side wall of this tunnel.

The water passes in the condenser are rather unusual. The entering water flows through the tubes occupying one vertical half of the condenser plus those enclosed by the air box, or cooler, at the lower end of the other vertical half. The water then returns through the tubes above the air cooler and overflows through a large cast iron nozzle and elbow which points down stream in the overflow canal.

Air and non-condensable vapors are removed from a header space in the cooler by means of a 35 by 39 in. rotative, dry vacuum pump. This pump is arranged for two-stage operation in one cylinder, one end of the cylinder serving practically to load the other. A direct-current motor with armature mounted on the crank shaft drives the unit. The normal speed of the pump is 100 r.p.m., but the motor is arranged for a speed reduction to 49 r.p.m. and need seldom be operated at or near its maximum.

head of a barometric condenser, as shown in Fig. 11. The relatively cold condensate is picked up by the second pump, before it has time to mix with the mass of water in the tank, and serves as injection water for the barometric condenser. The house-service alternator turbine and the boiler feed pump turbine exhaust into this barometric condenser, so that the condensate from the main unit takes up all the heat of the auxiliary steam. The foot of the barometric condenser is immersed in the other (or hot) end of the boiler feed tank. The mixture is there picked up by the boiler feed pump and delivered to the boilers.

The barometric condenser is therefore the equivalent of an open feed water heater in which exhaust steam from auxiliaries mixes with and heats the condensate from the main units, the mixture passing to the boilers as feed water. This condenser, however, offers possibilities not possessed by the ordinary open heater in that it is capable of maintaining a very low back pressure, if this is desired, or can be operated at any pressure between this and atmospheric. This property, taken in conjunction with the great variation of the

FIG. 8. SECTIONAL VIEW OF ONE OF THE 25,000 K.V.A. TURBO-GENERATOR UNITS

It will have been observed that all of the auxiliaries thus far mentioned are motor driven. As a matter of fact, this is true of all the auxiliaries in the plant with the exception of the boiler feed pumps. The latter are 1200 gal. per min., four-stage, double-suction, centrifugal pumps, driven by 350 h.p. steam turbines, at 2000 r.p.m.

The motor-driven auxiliaries may be operated, all or any of them, with power taken from the system bus, or with power taken from turbine driven, 1000 kw. alternators, known as house service alternators. In every case, that arrangement is used which, in conjunction with the other adjustments described below, will give the best heat balance for the station, under the conditions at the time existing.

What may be called the house service system is shown diagrammatically in Fig. 11. It is really a development of a method long used in both marine and stationary practice, in which a feed water heater is operated under vacuum. In the present instance, the wet vacuum pump of each main turbine unit discharges into one end of a large tank, known as the boiler feed tank. A centrifugal pump draws its water from the same end of this tank and discharges it into the

auxiliary turbine water-rate with variations of back pressure, gives great flexibility of control of the station heat balance.

This is shown diagrammatically in the upper left hand corner of Fig. 11. The straight lines represent total steam consumption of the house alternator turbines for the entire range of load at different back pressures. Assume that at some particular time with a given load and vacuum on the main unit, the load on the house alternator has the value indicated by the vertical line, and that the back pressure is that corresponding to the middle steam consumption line as at *a*. If the feed water temperature is too high it can be lowered by decreasing the back pressure, reducing the steam consumption to some such value as that shown at *c*. In this way, the feed water temperature can be accurately controlled, just enough auxiliary exhaust being made available to give the desired temperature.

The variation of the back pressure is obtained by means of a back-pressure valve in the exhaust line from the boiler feed pump turbine. If, under given constant conditions, this valve is partly closed down, the back pressure on the boiler feed pump turbine is increased and its steam consumption

for the same load is correspondingly raised. This, however, means that more steam enters the barometric condenser and, with a constant quantity and temperature of circulating water (main condensate), the temperature and pressure in the barometric condenser must rise. This, in turn, means higher back pressure on the house alternator turbine and it delivers more steam, still further raising the temperature.

Under certain conditions, this interchange may result in

so that continuous observation of this apparatus is readily obtained. An auxiliary gauge board containing instruments showing critical temperatures, pressures and quantities is located within easy view, and the results of all adjustments are readily seen.

This method of operating the auxiliaries appears very complicated when described on paper, but it has proved to be very simple in practice, and easy to handle. It possesses the following advantages which should be compared with methods more commonly used:

First. The one great advantage of steam driven auxiliaries is retained because exhaust steam is available for feed water heating;

Second. The quantity of auxiliary exhaust can be fitted to the ability of the feed water to absorb it;

Third. All the advantages of motor drive are obtained;

Fourth. Up to the ability of the feed water to absorb steam, the power used by the motor driven auxiliaries is produced at a thermal cost practically equal to that obtained in the case of steam driven auxiliaries;

Fifth. Since the feed water heater is normally operated under a vacuum, the feed water temperature is readily maintained at a value which will give ideal economizer operation;

Sixth. Because of the vacuum maintained in the feed water heater, air is readily removed from the feed water just before it enters the boiler feed pumps. In practice there is no re-absorption of air by the condensate between main condenser and boilers.

Another unusual feature is the provision for the distillation of all make-up water. Experience at Delray has shown

that the quantity of make-up required is readily held down to 1.5 or 2 per cent. Under such conditions, the apparatus required for distillation is small and the cost is negligible in comparison with the cost of boiler labor saved. The evaporator installed has a capacity of 12,000 lb. of vapor per hour and is heated by high pressure steam. The vapor formed in it passes directly to the barometric condenser in which it mixes with the auxiliary exhaust and thus becomes part of the feed water.

Many cases of boiler pitting and corrosion which are recorded in engineering literature have been attributed to the use of very pure water and the presence of a small quantity of scale-forming material has therefore been regarded as desirable. Most authorities now seem to believe that pure water is not responsible for such damage to good boiler metal, but that the blame is to be laid on small quantities of atmospheric carbon dioxide dissolved in what is assumed to be pure water.

In the Connors Creek plant, the feed water heating and storing system has been so designed as to prevent the absorption of air, so far as prevention is readily possible. Should

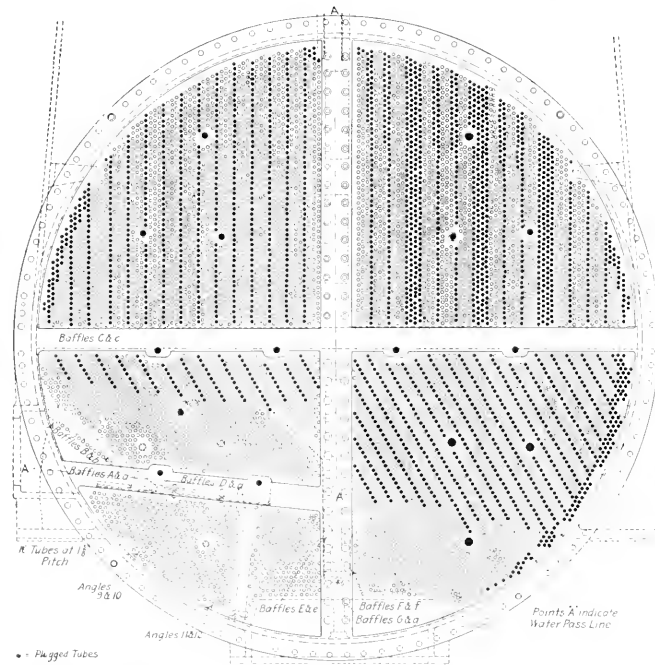

FIG. 9 DETAILS OF TUBE ARRANGEMENT IN THE CONDENSERS

a cumulative temperature rise, ending only when the pressure in the barometric becomes equal to that of the atmosphere and the auxiliary exhaust blows to waste. To prevent such an occurrence, the flood valve shown in Fig. 11 is provided. This is automatically opened whenever the temperature of the steam entering the barometric condenser exceeds a predetermined value. When it operates it admits comparatively cold water from the storage tanks, adding it to the normal supply of injection water entering the condenser, thus bringing the temperature down very quickly. It then automatically shuts off. Under very poor conditions of adjustment, this valve would continue to open and shut periodically until all of the water in the storage tank and boiler feed tank had been heated to about 212 deg. Fahr., but such a contingency is not probable because this would take a long time and the watch engineer would make necessary re-adjustments before the valve had acted many times.

The house alternator, boiler feed pump, and barometric injection pump are all grouped under the gallery shown at the right-hand side of the turbine room in Fig. 5. The natural position for the watch engineer is at the same place,

experience show that the provisions made are inadequate to insure safe boiler operation, there are several simple remedies. The simplest is probably the use of a very small quantity of an alkaline salt, experience having shown that if the water shows a mere trace of alkalinity it is apparently non-corrosive.

Another innovation in this station is the very complete provision for the recovery of radiation and electrical losses. Air enters the turbine room principally through louvers above the air washer shown in Fig. 5. This air, after being washed if necessary, passes down through the turbine room, picking up part of the heat lost by the steam apparatus. Ultimately it is drawn into the generator, picks up the heat representing the losses therein, and is discharged through a duct below the turbine room floor. This duct carries the heated air into the pipe gallery in which the stoker blowers are located. On its way to the blowers the air passes around the outside of the covering of all steam pipes, so that it also picks up the heat which these surrender to the surrounding atmosphere. In this way a large fraction of these unavoidable losses is conserved by being delivered to the boiler furnace, and just that much less heat need be supplied by fuel.

The electrical end of the plant also contains several unusual features. Notably, the generator leads are tied solidly to transformers which have a one to five ratio. These step the voltage up to 24,000, at which voltage all metering and switching is done. One of these transformers is shown to the left of the turbine room in Fig. 5 and also near the lower part of Fig. 13. There are three 8,333 k.v.a., single-phase water-cooled transformers per turbine.

FIG. 10 INTERIOR OF SCREEN HOUSE

A semi-diagrammatic layout of the complete electrical system is given in Fig. 12. The turbines will really be arranged in one straight row when all are installed, but the bus is actually built in the form of a loop, as shown in the figure. Section switches are provided between bus sections corresponding to each turbine and each of these sections is, in turn, divided into two approximately equal halves, thus localizing the effect of breakdowns to the greatest feasible extent. These section switches are non-automatic.

All switches are mounted in separate compartments on the floor immediately above the bus structures, as shown in Fig. 13. All machine, section and feeder switches are motor-operated, oil-break switches and are provided with lock type disconnecting switches on both sides, so that they can be com-

pletely killed for cleaning or repair. The doors on the oil switch and disconnect compartments are automatically locked by the closure of the oil switch.

On the floor above the switch gallery are located the storage battery (for auxiliaries, switches, and signals), the switchboard, and small electrical auxiliaries such as a balancer set, battery charging boosters, and a control motor-generator. The switchboard is located at what will ulti-

FIG. 11 ARRANGEMENT OF THE HOUSE SERVICE SYSTEM

mately be the center of length of the power house and is built in two sections arranged back to back, as shown in Fig. 13. The section facing the turbine room contains only the control switches and indicating instruments, while the rear board contains the integrating instruments and protective relays. All electrical equipment is controlled from this gallery, with the exception of the motor driven auxiliaries. The remote control switches for these are located to the left of the turbine foundation, as seen in Fig. 13. The auxiliary starting push buttons and the controllers for variable speed motors are located at the most convenient points, generally near the motor. The switch gear current for all apparatus handled from the main switchboard is supplied by the 25 kw. control motor-generator set mentioned above. This floats on a section of the storage battery, thus insuring continuity of service on the control.

In explanation of the fact that, as shown in Fig. 12, X_0 reactances have been installed and that the design therefore diverges from recent practice, attention should be called to the fact that the inherent reactance of the apparatus connected to the buses, together with the nature of the bus structure, is such that no protective reactances are deemed necessary. Provision has been made in the bus structure for the installation of additional supporting insulators opposite to those already in place when the connected generator capacity becomes such as to demand additional rigidity, also for feeder reactances if changes of distribution methods later should make these desirable.

Each turbine is normally excited at 250 volts by an exciter mounted on an extension of the generator shaft. In ordinary operation, the armature of the exciter supplies the generator field directly, voltage control being effected by a motor-driven dial switch on the exciter's field rheostat. The gen-

erator field may also be excited from the direct-current house service bus, in which case it is controlled by a motor operated rheostat in the main field circuit. The house service direct-current bus which supplies the direct-current auxiliaries and the emergency excitation, is supplied by motor generator sets, one to each station unit. The station storage battery also floats on this bus insuring continuity of service.

The use of alternating current motors for some auxiliaries

and direct current for others is determined by the following considerations: *a.* For any constant speed motor, alternating current was chosen. *b.* For speed variation of small range (as for the circulating pump where 15 per cent variation is sufficient), or of only occasional use (as the crane motors), alternating current motors with external resistances were chosen; except for the dry vacuum pumps, where the desirability of being able to start up from a condition of

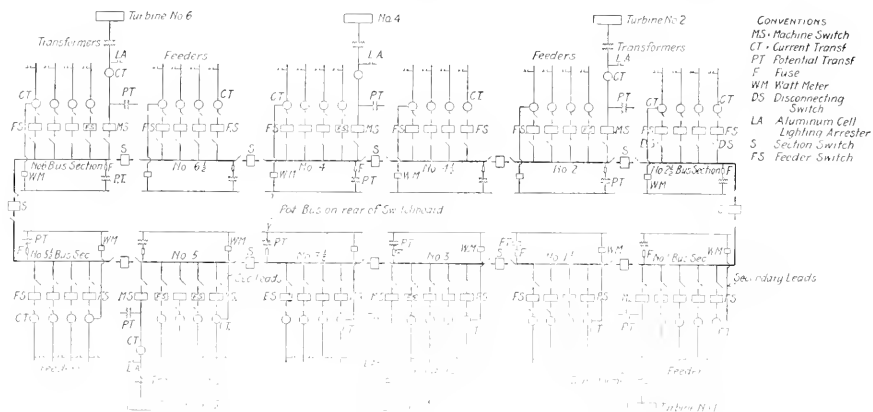

FIG. 12 LAYOUT OF THE COMPLETE ELECTRICAL SYSTEM

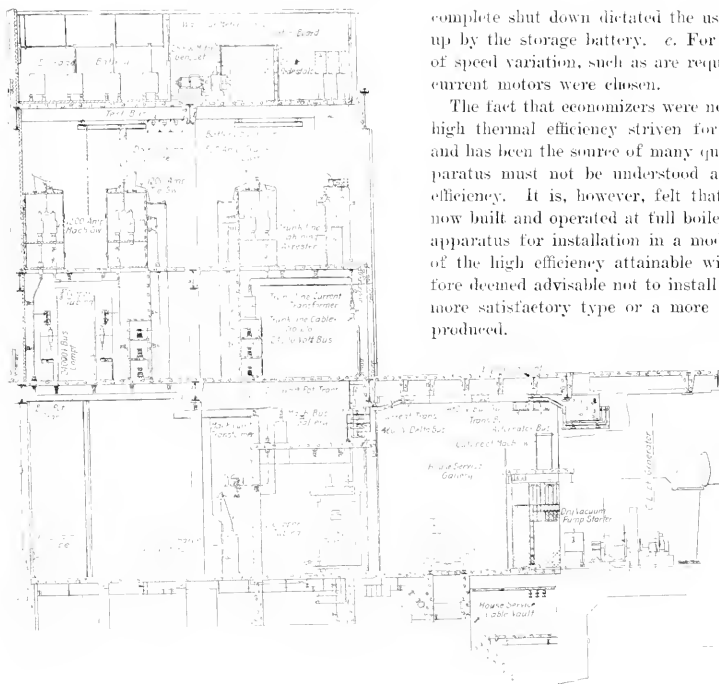

FIG. 13 SECTIONAL VIEW THROUGH SWITCH HOUSE

complete shut down dictated the use of a direct current motor backed up by the storage battery. *c.* For long ranges and exact adjustment of speed variation, such as are required by stokers and blowers, direct current motors were chosen.

The fact that economizers were not installed in this plant despite the high thermal efficiency striven for has caused considerable comment and has been the source of many questions. Failure to install such apparatus must not be understood as a declaration of disbelief in its efficiency. It is, however, felt that the cast iron tube economizer as now built and operated at full boiler pressure is not a proper piece of apparatus for installation in a modern high pressure plant. Because of the high efficiency attainable with the large boilers, it was therefore deemed advisable not to install economizers until such a time as a more satisfactory type or a more acceptable method of operating is produced.

NOTE. Since the presentation of this paper, the Connors Creek plant has been put in operation and thoroughly tested out. Small troubles, such as would be expected with a new and radical design of this sort have, of course, been met, but, on the whole, the plant has operated very smoothly indeed.

The operating record shows that the thermal efficiency of the plant will be about as high as was expected when it was laid down. The coal consumption per kilowatt-hour during the first two months of operation was considerably lower than the record performance of the Delray plant, and it is natural to expect that it will be further decreased as the operating methods are improved.

BOILER FAILURES AND WHAT THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS IS DOING TO PREVENT THEM

BY E. R. FISH, ST. LOUIS, MO.

Member of the Society

THE use of vessels for generating steam under pressure is as old as the use of steam itself, and for just that length of time there have been boiler failures of different kinds. The art and practice of boiler making has steadily progressed from its beginning with low pressures, imperfect and ill-suited materials, mediocre workmanship and unscientific designs, but it is, however, still far from perfect as is evidenced by continued disasters of varying magnitude.

Much has been written on the subject of boiler explosions, but Prof. R. H. Thurston was the first to put the matter in concrete and scientific shape, and I am quoting freely from his writings, for he expresses the conditions far better than I possibly can. Professor Thurston enunciated the following principles:

a Steam boiler explosions are always the result of well understood causes and are only mysterious, in any case, in the sense that available evidence may not point out with certainty which of the various well known causes may have operated in the given case.

b Boiler explosions are always preventable; it is always practicable to so design, construct and manage steam boilers that there shall be absolutely no danger of explosion.

c The proper course on the part of the designer, builder and user is to first use forms of boilers wherever practicable, such that, as Col. John Stevens said a century ago, "their explosion shall not be dangerous even should overpressure occur"; the same idea was enunciated by Fairbairn. Insure next good and well tested materials, good and well inspected workmanship and uniformly skillful management by men of experience and reliability. Regular, effective and thorough inspection constitutes a part of good management and an essential part.

He further stated that "steam boilers are magazines of energy forcibly restraining explosive powers of such magnitude as few can compute or realize." As an example, I select from one of the tables he calculated covering a number of different types and sizes of boilers, a return tubular boiler of 60 h.p. working at 75 lb. pressure. The weight of such a boiler is approximately 9500 lb., the water it contains weighs 8200 lb. and the steam 21 lb. The available stored energy in the water is 50,008,790 ft. lb. and in the steam 1,022,730 ft. lb., or a total of 51,031,520 ft. lb., which is sufficient to project the boiler only to a height of 5372 ft. with an initial velocity of 588 ft. per sec.

Quoting further from Thurston:

It is seen that the energy stored in the steam boiler, in the form of heat, is mainly that of the heated water and comparatively little resides in the steam; so that it follows that a boiler well filled with water is vastly more dangerous in case it explodes, than if exploded as a consequence of low water. The steam itself is quite incompetent to perform the work of the very destructive explosions often observed, and where the boiler is thrown, with the violence of a projectile from a piece of ordnance, against surrounding objects or hundreds of feet into the air; for it must be remembered that in no case can more than a small fraction of this computed total

energy be actually applied to the propulsion of the boiler. Most of it is inevitably wasted in other directions.

Comparing the energy of water and of steam in the steam boiler with that of gunpowder, as used in ordnance, it has been found that at high pressures the former become possible rivals of the latter. Taking the value of gunpowder at what the writer would consider a fair figure, 250,000 ft. lb. per lb., it is seen that a cubic foot of heated water, under a pressure of 60 or 70 lb. per sq. in., has about the same energy as one pound of gunpowder.

A powder magazine under one of our modern tall buildings, or under the sidewalk in Broadway, would be objected to very seriously by citizens compelled to make that great thoroughfare their daily walk, and if compelled to submit to its threatening presence, they would certainly insist upon the most stringent precautions being taken to insure safety against the liberation of its stored energy; but scores of steam boilers are so concealed and the laws of the city and of the State relating to their care are of the most lax and ineffective character.

Good design, good workmanship and good management have been said to be the three safeguards against destructive explosion. Good design, in any case, presupposes a well read, well educated and an experienced designer.

Good construction involves the selection of good materials and their proper use in building the boiler. This means, in turn, iron, or more commonly, steel in which ductility and toughness, rather than simple strength, are the special characteristics, and perfect uniformity in the several sheets of which the boiler is made up. Good construction involves the exact production of the required forms of parts and their riveting, or welding, together without loss of strength or introduction of stress. Good management means the regular and moderate firing of the furnace, constant inspection of the parts liable to corrosion or other injury, and maintenance in as perfect condition as possible by constant repairing of injured parts. It also includes the periodical inspection and test which now constitute the basis of insurance.

All failures are due to preventable and familiar causes that might be evaded by the designer, the builder or the operator. Whatever may be said of the many known and possibly unknown, the certain, the probable and the possible causes, mysterious or otherwise, of boiler explosions, it is certain that a boiler is practically safe for all time in the hands of a good engineer or fireman if originally well designed, well constructed and properly set. Its safety is assured by a correct system of inspection either on the part of the person in charge or of the official inspector, or, more usually and properly, of both working together honestly and in good faith. A correct system of inspection is the check upon every defect of design, of construction and of operation.

Inspection should be made at fixed regular intervals and should be conducted by an inspector experienced, reliable, of good judgment and absolutely conscientious. He should be accompanied in his inspection by the responsible man in charge of the boiler, and his examination should be deliberate, thorough and unimpeachable. The time should be so chosen that the work may be done satisfactorily, without haste or interruption. The method should be—careful examination by eye, hand and a light hammer, of every sheet, stay, brace, tube and rivet in the boiler. Defective riveting, the most common defect, should be looked for in every seam. Cracks in the seam, under the lap, are not unusual and are very difficult to find in many cases, but if undiscovered, they will be likely to prove disastrous. Corroded sheets and tubes, bad bracing, sediment and incrustation are all promptly de-

tested and readily visible in any case. The thickness of thinned sheets, corroded on either side, or of blisters, may be judged by the action of the sheet under the hammer, and many defects, entirely invisible, are found by the experienced inspector by the hand and ear, reinforced by the use of this tool. It is evident that no inspection worthy of the name can be made unless with the boiler dry and empty, and accessible in every part. A design which does not permit this should be condemned offhand. Tests by hydraulic pressure, though useful, and in the judgment of the writer indispensable, cannot be, in any case, allowed to supersede the real inspection above outlined.

Whatever may be the fact, however, more perfect and effective methods of inspection must be legally introduced and well enforced before the steam boiler explosion can become extinct, with its resultant destruction each year of hundreds of lives and millions of dollars' worth of property. With such methods, universally practiced, steam boiler explosions will become unknown.

Written some 25 years ago, the advice thus given has been to a considerable extent followed, but there still remains much to be accomplished, particularly as regards proper state legislation.

There are approximately 1500 boiler explosions of varying intensities each year in this country, averaging 400 or 500 persons killed, 700 or 800 injured and many hundreds of thousands of dollars damage to property.

General methods for proportioning the several dimensions of the boiler structure have long been known and in general use, although modified from time to time by tacit consent as experience or new and improved materials and methods became available. These rules, if such they may be called, have varied greatly in details in various places, depending on the personal opinions and experiences of the man or men formulating them. It can readily be appreciated that with the great multiplication of such regulations in the past few years, manufacturers who do a wide interstate business have become confronted with a condition that is hard to meet. In addition there are the infinite variety of private specifications written by consulting engineers and others, that differ through exceedingly wide limits and which represent the judgment of one or at best a very few men. Under such conditions it is impossible to manufacture economically, for a boiler built to meet the requirements of one place may be rejected in some other locality.

In 1905 there occurred in Brockton, Mass., an explosion which caused \$250,000 damage, the loss of 58 lives and 117 injuries. This aroused the State of Massachusetts to action, the result of which was the enactment of legislation providing for the licensing of engineers and firemen, and governing the construction, installation and inspection of boilers. A Board of Boiler Rules was created for the purpose of formulating construction standards; its labors resulted in the most complete, scientific and logical set of regulations that had ever been promulgated. These rules have been quite extensively copied all over the country.

However, the need of regulations that would represent the consensus of the opinion and experience of the whole country rather than that of any one locality, prompted Col. E. D. Meier, when president of the American Society of Mechanical Engineers, to appoint a committee to formulate such rules. After more than 3½ years' real work, including numerous and lengthy discussions, often heated and acrimonious, the A. S. M. E. Boiler Code, as it is popularly known, has resulted and represents as nearly as it is humanly possible what

those who are best qualified to know believe to be the best boiler practice.

There is much in the Code that is absolutely new. Probably only such a body as formulated it could have prevailed upon certain antagonistic manufacturers of materials and fixtures to get together and agree on uniform specifications for their products. This is notably the case with safety valve manufacturers and tube makers; possibly the most remarkable achievement is the very definite regulations, most of which are entirely new, relative to safety valves.

The Code covers the construction of stationary boilers and allowable working pressures, and is divided into two parts. Part I, Section I, applies to new installations of power boilers; Part I, Section II, to new installations of heating boilers, and Part II applies to existing installations of all boilers. Obviously it is necessary to extend considerable leniency to boilers now in use, as to do otherwise would work a tremendous hardship on thousands of steam users.

In brief, the subjects covered by the Code are indicated by the sub-headings: *Selection of Materials*, wherein is specified what grades of materials may be used for various parts and places in the boiler; *Ultimate Strength of Material Used in Computing Joints*, in which unit stresses forming the basis of calculations are given; *Minimum Thicknesses of Plates and Tubes*, to prevent "skinning" the job; *Specifications for boiler plate steel, rivet steel, staybolt steel, steel bars, steel castings, gray iron castings, rivet iron, staybolt iron, and tubes*, all of course as pertaining specifically to boiler practice. Then follow under the heading: *Construction and Maximum Allowable Working Pressures for Power Boilers*, detailed rules for determining strengths and efficiencies of joints, etc., with examples and stating in what way much of the work shall be executed. Then come the subjects of *Manholes, Washout Holes, Threaded Openings, Safety Valves, Water and Steam Gauges, and Fittings and Appliances*, wherein are given methods for determining quantities, sizes, limitations as to location and kind of metals to be used. Some general regulations as to settings to promote safety in operation, as to how hydrostatic tests shall be made and finally the method of stamping to show conformity of the structure with the Code, are given.

The rules covering boilers used exclusively for heating cover substantially the same ground, but are much more brief.

In Part II appear the rules for determining the working pressure to be allowed on existing boilers, and what fittings must be provided and how applied. On boilers now in service, will be required many minor changes if the Code is followed, but there are none but what should be made in any event. This section also provides for the gradual amortization, to use a commercial and financial term, of boilers now in use and not built to the Society standard.

An *Appendix* gives full examples of various riveted joints and methods of calculation, as well as of braced and stayed surfaces, method of computing safety valves, also how fusible plugs should be located in the various types of boilers, and standard dimensions for flanged pipe fittings.

In my opinion it is amply sufficient for any one desiring to purchase a boiler plant, after having determined the working pressure and the size and type of units required, to merely specify that the boiler is to be built according to the A. S. M. E. Code. By so doing he will get from any reputable

manufacturer a well constructed structure entirely suited to its purpose. If preferred, the material and workmanship may be checked by some inspecting agency. From a manufacturer's standpoint, my plea is for country-wide uniformity of requirements, and thus the general adoption of the Code makes possible. It couples together economical manufacturing with the all-pervading cry of Safety First.

In compiling this Code, therefore, the American Society of Mechanical Engineers has provided a substantial basis for boiler specifications and legislation. The Society cannot go further than to say that, in the estimation of those best qualified to judge, these are the most rational rules and regulations for boiler construction. The enforcement of the rules must be left to the activities of other agencies. A very considerable number of the boiler manufacturers of the country have already gotten together on two occasions, first, on September 19, 1914, and again on March 29, 1915, with the avowed purpose of furthering the universal use of the Society's Code, and at the last named meeting, the Code was unanimously endorsed and steps taken to launch a movement to prevail upon the various States to enact legislation putting it into legal effect. It seems impracticable to do this in any other way. The State of Ohio has already made this enactment and the State of Wisconsin will in all probability do so, to be effective January 1, 1916.

Educational movements will have to be started in various other States in order to be at all sure of any success at future

state legislative sessions. Last fall it was hoped that the Code would be completed in time to present the matter definitely to the numerous legislatures that were in session early this year, but that proved to be impracticable. One of the forms of education is to persuade those who have positive ideas of their own that such should be subservient to this broader consensus of opinion, and only by so doing can country-wide uniformity, so exceedingly desirable, be attained. Already there are some objections raised to minor points, which indicate that there are difficulties to be overcome in arriving at the desired end.

That this effort of the Society in bringing out the Code will help tremendously, primarily in bettering boiler construction generally, and secondarily, in smoothing the way of manufacturers, thus redounding to the financial benefit of the user, needs no further argument. The Code has already attained such momentum as to make it a powerful factor.

It can truly be said that what the American Society of Mechanical Engineers is doing to prevent boiler failures in this country is something which could have been done by no other organization and that the effect will be far reaching and long continued.

NOTE. Since this paper was written, an action has been taken at the annual convention of the American Boiler Manufacturers Association, June 22, to start a nation-wide movement including every interest in any way affected. This has resulted in the formation of the American Uniform Boiler Law Society, whose function will be to promote the adoption of the A. S. M. E. Boiler Code by legislative bodies.

TURBINES VS. ENGINES IN UNITS OF SMALL CAPACITIES

By J. S. BARSTOW, PHILADELPHIA, PA.

Non-Member

THE term "units of small capacities" as used herein is intended to include steam turbines and engines of less than 500 h.p. capacity. The paper will necessarily deal largely with the prime movers of auxiliary apparatus in power plants, since the tendency of the times in all industries, and particularly in central stations, is toward the concentration of power in a few units of large size and uniform capacity as opposed to a multiplicity of small units of different capacities. However, there is a wide field for power application where the steam-operated prime movers are of relatively small size, and where transmitted or central station energy is not able to successfully compete; and it is intended to discuss the type of apparatus best suited in these cases, as well as the type of apparatus which it is advisable to employ for auxiliary units in large plants or central stations.

There are certain definite fields where the small turbine is of conceded superiority, and other fields wherein the engine must hold sway. The desirability of the one as compared with the other is largely determined by the following factors, which govern the adaptability, cost and economy of the equipment to be installed for any given service:

a Speed conditions and limitations involving consideration of maximum or minimum permissible speed, and whether

the driven apparatus is of the constant or variable speed class

- b* Steam pressure and temperature conditions involving consideration of initial and final pressures, and superheat, if any
- c* Power capacity of apparatus
- d* Relative space requirements of turbine and engine units involving consideration of available room, character of power house construction and cost of foundation or other supporting structure
- e* Use or application, if any, of the exhaust steam for feed water heating, steam heating or process purposes
- f* Available cooling water supply, if the turbine or engine is to run condensing, involving also consideration of the temperature of the water and whether it must be artificially cooled and re-circulated
- g* Operating conditions including consideration of attendance, oiling, starting and stopping, vibration, noise, etc.
- h* Relative cost of complete installations including necessary foundations, piping and condenser equipment, if any

As to the practicability of the small turbine, it may be said that not until about 20 years ago was any really practicable apparatus of this kind developed, and even up to ten years ago the turbine was looked upon mainly as an experiment. The last few years have witnessed, however, the practical perfection of this type of prime mover in sizes

¹ 818 Pennsylvania Bldg., 15th and Chestnut Sts.

Presented at the Philadelphia local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, April 12, 1915.

as large as 50,000 h.p., with units of 30,000 h.p. quite common in large central stations. They have also seen quite as much good work done in the perfection of small turbine units as in the development of very large ones, and the turbine in all sizes is quite as well developed to-day as is the steam engine after more than one hundred years of constant effort and improvement.

The writer has no intention of reflecting on the great work done by steam engineers in the development of the reciprocating steam engine. The work of these men, which was the harder task, accelerated the evolution of the turbine, the science of thermodynamics underlying the final development and perfection of both.

The present day builders of reciprocating engines are able to report further progress, however, and as a result of their recent efforts there have appeared the rejuvenated poppet valve engine adapted to the use of highly superheated steam; the unafflow or parallel-flow engine, also with poppet type valves, in which cylinder condensation is reduced by causing the steam to travel in one direction only; and the small self-contained power plant, or "locomobile," consisting of a steam engine mounted upon a tubular boiler and operating at high superheat. All these engines are adaptations from European practice, where, owing to the high cost of fuel and the relatively larger number of technically-trained operators, they have found high favor.

Mention also should be made of the power plant formerly used in the White motor car, which, owing to its high steam pressure, superheat and speed, gave remarkably low steam consumptions. In a series of tests, reported in the Transactions of the Society, Vol. 28, pages 598-9, the average steam consumption was 12.7 lb. per delivered h.p.-hr., operating at 850 r.p.m.; steam at 275 lb.; superheat, 349 deg. Fahr.; noncondensing exhaust.

Tests have recently been reported by the manufacturers which give the steam consumption of a 115 h.p. Buckeye-mobile, running at 248 r.p.m.; steam at 210 lb.; initial superheat, 171 deg. Fahr.; noncondensing, as 13.3 lb. per i.h.p.-hr. This unit produced an i.h.p.-hr. on 1.33 lb. of coal having a calorific value of 14,500 B.t.u. per lb. A 169 h.p. unit running at 200 r.p.m.; steam at 209 lb.; initial superheat, 218 deg. Fahr.; vacuum 25.7 in., showed a water rate of 9.2 lb. per i.h.p.-hr. The coal consumption, using fuel with a calorific value of 14,209 B.t.u. per lb., was 1.08 lb. per i.h.p.-hr.

While there is the possibility that the use of a shell type of boiler for high pressures will be considered by many engineers as unwise, especially for installation in densely populated centers, it is still too early to predict what the future of this apparatus is to be. However, as indicating what may be accomplished in fuel economy in a well-designed plant of small size, the results reported are interesting.

SPEED LIMITATIONS

The question of speed limitations is of first importance in selecting the type of prime mover. Since high peripheral velocities are necessary in order to efficiently utilize the energy of a steam jet in the turbine type of apparatus, the latter shows its lowest water rate when running at a constant high speed. Where the character of the service is such as to require speed variation or reversal in direction, or where the speed is necessarily low, the turbine is unsuited and the engine is much better adapted.

In engine installations, the minimum permissible speed has an important bearing on the question of operation. If an engine is run at very high speeds, operating troubles are sure to be numerous, the upkeep excessive and the service unsatisfactory. The lack of driven apparatus designed to run efficiently at speeds consistent with high turbine economy has, in the past, frequently dictated the use of engine prime movers for many kinds of work.

Although speed reduction gears are by no means new, having been used with the turbine almost from the beginning of its commercial development, improvements in high speed gearing, as well as in the manufacture of high speed direct connected generators, blowers and pumps, running at 3,000 r.p.m. and above, have greatly increased the possibilities for turbine installations. Direct current generators as small as 10 kw. capacity, and 60 cycle alternators of capacities as low as 150 kw., designed for gear drive, are now offered. The manufacturers claim for these machines that the increased efficiency of the higher speed turbine, together with the saving effected in the generator construction by reason of the slower speed permissible in the driven end, justify the expense and complication which the gears introduce.

While many may still prefer a direct connection, the increasing popularity of the gear drive, especially for direct current generators, blowers and pumps, would seem to indicate that the gears are here to stay, and that when properly constructed and installed, there is no valid objection to their use.

For power station work, where some of the auxiliaries are usually motor driven, the exhaust steam can be entirely condensed in the feedwater heater, and the water rate of the steam driven auxiliaries is not a limiting factor, while reliability, accessibility, low maintenance and labor costs are of more vital importance. Power station designers have always exhibited, therefore, a strong preference for turbo-auxiliary units, and there is now a decided tendency toward geared installations.

The selection of turbines for auxiliaries is largely influenced by the high speed at which small engine units are run, which makes it exceedingly difficult to keep them in continuous service, and almost impossible to secure smooth, quiet operation. Such reciprocating units require close attention, and must be shut down, overhauled and adjusted at frequent intervals; the maintenance is high and serious breakdowns are by no means rare. An accident to a circulating or hot well pump, for example, usually necessitates a shutdown of the main generator, with consequent loss of production, and often, in the case of a public utilities plant, loss of prestige and the incurrence of public ill-will. In all central stations, therefore, where the main units are few in number and of large size, high economy as compared with continuous operation becomes relatively unimportant, and turbine driven circulating hot well and boiler feed pumps are almost invariably used.

Motor driven exciters are largely used in alternating current stations, a steam driven exciter being provided for starting up and as a reserve unit. Here also, since the steam driven set is idle a large part of the time, high economy is not so important and the saving of floor space and elimination of vibration will often decide the question in favor of the turbine. In fact, in all direct current generator sets of 50 kw. capacity or less, the high speed necessary for the engine generally makes it undesirable.

For driving fans of large capacity at low pressures, say less than $1\frac{1}{2}$ in. of water, for induced draft, hot air heating and ventilating systems and the like, the engine seems best suited. Fans built for this service ordinarily run at less than 200 r.p.m. and are usually of the paddle-wheel type, which is better suited to these conditions than the multi-blade high speed fan. In induced draft work, load fluctuation may require frequent changes in speed, the engine being under the control of a throttling regulator which is automatically actuated by a change of steam pressure. These conditions are quite unfavorable to turbine economy, and a suitably designed and well-constructed engine will give more satisfactory results.

In like manner, where we consider the pumping of large quantities of water against low variable heads (conditions which are encountered in drainage or sewage pumping stations) the turbine must yield place to its rival. These pumps may have single runners of large diameters or may be of the multi-impeller type, but in either case, the speed is below the economical turbine range, even when a gear is used, while the engine, at low speed, has an opportunity to make its best showing, steam economy and operating troubles considered. Where the lift is variable, speed changes are required and the engine is almost always more suitable.

As a typical installation may be mentioned the four 76 in. centrifugal pumps for the Plaquemine and Jefferson Drainage District of Louisiana. Here the pump speed varies from 50 r.p.m. for 1 ft. head and 135,000 gal. per min. to 115 r.p.m. for 13 ft. head and 90,000 gal. per min. The best duty was 92,600,000 ft. lb. per 1000 lb. of dry steam, corresponding to 21.4 lb. of steam per water horse-power obtained at 87 r.p.m. for 7 ft. head and 130,000 gal. per min. The prime mover is a compound engine operating at 170 lb. steam and 25.7 in. vacuum.

The use of underfed stokers operating under heavy forced draft and capable of developing high boiler ratings, has become quite common as a means of reducing fixed charges and boiler banking losses in railway and lighting plants, and particularly those maintained as standbys to hydro-electric stations. These furnaces often carry in the air duct pressures as high as 6 in. of water, and the high speed multi-blade fan makes the better installation, particularly where one fan serves several boilers, as the blower units frequently become excessively large when run slower than 400 r.p.m. At this speed the engine drive is an uncertain and expensive proposition.

Furthermore, as such stokers at best are capable of only from one-quarter to one-third their maximum capacity under natural draft conditions, a blower breakdown under a peak load is a serious matter and the ability of the turbine to stand up under the conditions imposed justly entitles it to the preference which it is accorded.

For driving directly connected alternators, a frequency of 25 cycles fixes the maximum speed at 1500 r.p.m., which is too low for the best turbine performance. In 60-cycle apparatus, where a speed of 3600 r.p.m. is possible, the turbine shows to better advantage.

STEAM PRESSURE AND TEMPERATURE CONDITIONS

The highly economical steam turbine must necessarily be operated condensing, but, as previously pointed out, there are many cases where high steam economy is not the most important consideration and the noncondensing turbine often

finds favor over the steam engine. One of the large heat losses incurred in the steam engine is that due to cylinder condensation and one of the common methods of reducing it to limit the range of temperature through which the steam is allowed to work in a single cylinder. For this reason simple engines are better adapted for low steam pressures, while compound and triple expansion engines are advisable for high pressure and high temperature ranges, particularly if the load is uniform.

The engine as a rule develops mechanical troubles with high superheat, especially where the steam valves have much travel under unbalanced pressures. The consensus of opinion seems to be that for slide or gridiron valve gears, a temperature of 400 deg. Fahr. to 425 deg. Fahr. should not be exceeded, while the best point for the Corliss type engine will be found below 450 deg. Fahr. Above these limits lubrication is unsatisfactory and distortion of the parts is apt to give trouble.

In European practice, superheating is much more common than in this country, a superheater being considered quite as indispensable as a feed water heater and the poppet valve engine, which was first perfected abroad, is accordingly better suited for high superheat conditions than the type of gear commonly used in American engines.

A difficulty sometimes encountered with engines using high superheat is the warping of the cylinder, the curvature being caused by the higher temperature which prevails in the metal next to the steam chest. Precaution is taken by some builders to avoid such trouble by leading the steam by two independent pipes, entirely separate from the cylinder barrel, from the throttle directly to the steam valves.

For power plant auxiliaries, it would appear that turbines which experience little difficulty from high temperatures will be more and more widely adopted while engines will be less commonly used, especially so as steam pressures and superheats are constantly increasing, it being not unusual for new plants to be designed to carry from 200 to 225 lb. with superheats of 150 deg. Fahr. and over. With steam engines running under high vacuum, above 27 in., the great volume of steam to be handled increases the size of the engine cylinders, and the size of ports through which the steam must pass, to such an extent as to make the engines very expensive if not of impracticable construction. The cost of an engine which would permit of complete expansion to such a terminal pressure, together with the increase in cylinder condensation, due to the greater range of temperature, would make the high vacuum undesirable.

The turbine, on the other hand, can be designed to operate on very low terminal pressures with comparatively slight increase of cost; its action as a heat machine is such that a greater expansion can be utilized and the economy is greatly improved by any increase in vacuum. When run non-condensing, as is well known, the turbine is less economical than the non-condensing engine.

In plants where the exhaust is atmospheric and cannot be applied to any useful purpose, the engine best fills the conditions, provided space is available and the speed may be made low enough to ensure smooth, quiet running. Such an application is found in direct current generator sets of 100 kw. capacity and larger, in hotels, office buildings and hospitals, where the exhaust is used for steam heating in winter and must be wasted for several months in the year.

POWER CAPACITY OF APPARATUS

The lower cost of large turbine units and the greater reliability of this kind of apparatus in regular service, coupled with the smaller space taken up by turbines as compared with engines, has practically put the engine out of the running as far as large power plants are concerned. Where 60-cycle apparatus is installed and condensing units are used, the engine has no field beyond the 500 kw. mark, while with direct connected 25-cycle apparatus, the engine must stop beyond the 1000 kw. limit, and with the perfection of high speed reduction gears, it is doubtful if 25-cycle engine driven generators can compete with turbine apparatus of even 500 kw. capacity. The reduction gear is also rapidly driving the engine from the direct current field in units of all sizes, above say 200 kw. capacity. At the same time, elimination of operating troubles by the use of direct connected turbines for exciter purposes is fast causing the turbine to supplant the engine for this service.

In the case of non-condensing units where moderate speeds are required, the engine must continue to hold the field, though special conditions may make the non-condensing turbine a factor to be considered. In this connection, one installation might be mentioned where a belted turbine of 750 h.p. capacity, running at 1500 r.p.m., is used for driving the constant speed shafting of a paper mill, it being contended that the greater uniformity in relative speed secured by the turbine results in fewer breaks and a more satisfactory product. In this case, the exhaust steam is, of course, utilized in the dryers of the machine, and the variable speed power is supplied by direct current motors.

RELATIVE SPACE REQUIREMENTS

Owing to the freedom from reciprocating motion, the foundations required for turbines are of small size and light weight, there being little vibration to be absorbed when the alignment and balancing are well done. The small sizes can be safely operated on floors of usual construction, designed for the ordinary floor loads. There is no difficulty experienced with the transmission of vibration to the structural members of the building or to the piping system.

The small space required for the installation of a turbine gives it an advantage in water works plants, operating against moderately high heads. The vertical triple expansion engine, which was formerly used almost exclusively for such work, requires a strong massive substructure to absorb the shock and distribute the weight, and a deep pit to accommodate the water end. Where foundation or other construction difficulties are encountered in this work, the cost may easily climb to a high figure, and in a case under the author's personal observation the additional cost of building, incidental to the use of the vertical triple engine, would have more than paid for a turbine driven centrifugal pump, while the fixed charges on the pump alone were more than four times the cost of the fuel required to run it to full capacity ten hours per day.

The turbine driven pump is not capable of showing on test the high duty of the vertical triple engine—which is one of the most economical steam engines—but the great difference in the first cost of installation often makes the turbo set decidedly preferable, especially when the saving in building is considered. A geared turbine unit to pump 100 million gallons per day against a 56 ft. head was recently in-

stalled in Ross Station, Pittsburgh; the pump speed was 350 r.p.m. and that of the turbine 3600 r.p.m. On the duty trial, with steam at 151 lb. and vacuum 28.38 in., the pump showed a performance, including power consumed by the auxiliaries, of 120.5 million ft. lb. per 1000 lb. of dry steam, corresponding to 16.44 lb. of steam per w.h.p.h.r. Six similar sets, ranging in capacity from 6½ to 30 million gallons per day capacity, are now in process of construction. The displacement of the reciprocating engine from a field where its superiority was formerly unquestioned, shows the substantial progress which has been made in the development of the steam turbine and the centrifugal pump.

For boiler feed pumps of more than 250 gal. per min. capacity, the turbine is often used, and on account of its small size, usually results in a neater and more compact layout. Where regulation by throttling is unnecessary, and the pumps run at or near capacity, the economy as compared with the direct acting type is good and can be better maintained. Valve renewal and packing troubles are avoided. The overload capacity of the centrifugal type, however, is small and the delivery of the pump must be proportioned to meet the maximum demand, not the average boiler horsepower requirements. In the smaller sizes, the cost of turbine units is high; where the load fluctuates widely and the speed must vary, the economy is poor and it is better to install reciprocating pumps.

In the modern plant containing large turbo-generator units, space limitations in the basement arrangements are an important consideration. With the high vacua carried, large volumes of water must be handled and the turbine drive for circulating, condensation and air removal pumps is in many cases the proper selection. Such condenser sets have a compact arrangement, especially when a single turbine is used to drive all the pumps, which greatly relieves the crowded condition that would otherwise obtain. As previously stated, they are also preferable as being more reliable.

The turbo-compressor supplying air to blast furnaces under pressures ranging from 20 lb. to 30 lb. has almost entirely supplanted the compound reciprocating blowing engine. One large concern formerly in this work has abandoned the construction of blowing engines and is now building turbine apparatus exclusively. For this service, the turbine may be run from 2500 to 4000 r.p.m., and there is a great saving of weight and space, as an engine of this type is six or eight times as heavy as the centrifugal blower, and consequently costs much more. It can be installed comfortably where the blowing engine would be out of the question, and in new installations the relative cost of building and foundation for the two types has a direct and important bearing.

UTILIZATION OF EXHAUST STEAM

The advantage of an oil-free exhaust is in many plants of considerable value, and especially so in manufacturing processes where steam is used, as there are many such opportunities for the utilization of low pressure steam if the oil has been eliminated. For the blocking of hats and in the treatment of other felt and textile products, absolutely clean steam is necessary. As heretofore mentioned, paper manufacturers have used turbines for driving the constant speed mechanism of paper machines in order to secure more uniform angular velocity, and to avoid among other things

trouble caused by oil accumulation in the drying rolls. The danger of oil deposits in high pressure steam boilers is well-known to all.

In chemical processes where steam is used for precipitation, as in the precipitation of magnesia, a small fraction of a grain of oil per gallon will often retard the process or cause the precipitate to be of an entirely different character from that obtained with oil-free steam. The separation of the oil in exhaust steam is never absolutely complete, and fatty constituents are especially apt to pass the separator.

AVAILABLE COOLING WATER SUPPLY

Where the available cooling water supply is limited and must be artificially cooled and recirculated, the cost of the cooling apparatus and the power required must be considered. The conditions will, perhaps, be best illustrated by an example: Assuming a turbine to run at 28 in. vacuum, and a temperature rise of the cooling water to within 10 deg. of that due to the vacuum, the circulation of 52 units by weight of cooling water for each unit of steam condensed will be necessary. In the case of the engine, which will operate at, say, 26 in. vacuum, other conditions remaining the same, there will be from 25 to 27 lb. of cooling water to be handled for each pound of steam condensed.

With a cooling pond returning water at 90 deg. to produce 27 in. vacuum in a turbine plant, the pumps must circulate 70 units of cooling water per lb. of steam, as against, say, 30 units required to produce 25 in. vacuum for the reciprocating engine.

OPERATING ADVANTAGES

From the operating point of view, the turbine possesses a great advantage in the simplicity of its construction, a factor which tends toward increased reliability and lower cost of maintenance. It can usually be more quickly started and loaded and, in operation, usually requires very much less attention than an engine unit of corresponding capacity. The lubricating arrangements are few in number and of simple design.

SUMMARY

Summarizing the foregoing, the fields of usefulness of the turbine and engine may be briefly stated to be:

APPLICABILITY OF TURBINES

- 1 *Direct connected units, operating condensing.* 60-cycle generators in all sizes, also 25-cycle generators above 1000 kw. capacity. (This paper is, however, not intended to deal with units of this size.)

Direct current generators in sizes up to 1000 kw. capacity, including exciter units of all sizes.

Centrifugal pumping machinery operating under substantially constant head and quantity conditions, and at moderately high head, say from 100 ft. up, depending upon the size of the unit.

Fans and blowers for delivering air at pressures from 1½ in. water column to 30 lb. per sq. in.

- 2 *Direct connected units, operating non-condensing* for all the above purposes, in those cases wherein steam economy is not the prime factor or where the exhaust steam can be completely utilized, and, in the latter case, particularly where oil free exhaust steam is desirable or essential.
- 3 *Gearred units,* operating either condensing or non-condensing for all the above mentioned applications, and in addition, many others which would otherwise fall in the category of the steam engine, on account of the relatively slow speed of the apparatus to be driven.

APPLICABILITY OF ENGINES

- 1 *Non-condensing units, direct connected or belted and used for driving:*

Electric generators of all classes excepting exciter sets of small capacity, unless belted from the main engine.

Centrifugal pumping machinery, operating under variable head and quality conditions and at relatively low heads, say up to 100 ft., depending on the capacity of the unit.

Pumps and compressors for delivering water or gases in relatively small quantities and at relatively high pressures—in the case of pumps at pressures above 100 lb. per sq. in. and in the case of compressors at pressures from 1 lb. per sq. in. and above.

Fans and blowers (including induced draft fans) for handling air in variable quantities and at relatively low pressures, say not over 5 in. water column.

Line shafts of mills, where the driven apparatus is closely grouped and the load factor is good.

All apparatus requiring reversal in direction of rotation, as in hoisting engines and engines for traction purposes.

- 2 *Condensing units direct connected or belted,* for all the above purposes, particularly where the condensing water supply is limited, and where the water must be re-cooled and re-circulated.

SPRING MEETING PAPERS

IN the August issue of The Journal were published eight of the fourteen papers presented at the Spring Meeting held at Buffalo, June 22-25. The six remaining papers are here published in abstract, together with accounts of the discussions following them. Pamphlet copies of the complete papers without the discussion are available at the prices named in each case. Later, the papers which are to appear in Volume 37 of Transactions, may be had in pamphlet form with the discussion added.

SOME MECHANICAL FEATURES OF THE HYDRATION OF PORTLAND CEMENT AND THE MAKING OF CONCRETE AS REVEALED BY MICROSCOPIC STUDY

BY NATHAN C. JOHNSON, NEW YORK, N. Y.

Member of the Society

THE data embodied in this paper have been obtained in the course of a research conducted in the Sibley College laboratories at Cornell University. At the beginning of this research, it was believed that the obtaining of more effective hydration was a prime factor in the production of durable concrete. It has long been known experimentally that a set cement or concrete could be reground and a new set obtained on gaging with water;¹ but the extent to which unhydrated particles were present in the mass was first made visually evident, so far as the author is aware, by experiments conducted in 1911 in the Sibley College laboratories at Cornell.² In these experiments, neat cement briquettes were surfaced and polished, as in the metallography of steel; and the degree of hydration obtained in different ways was more or less accurately judged by the appearance of these polished sections, viewed through the microscope. Later this same procedure was extended to the examination of 1:3 standard sand mortars and still later to the examination of field concretes.

In a section of such 1:3 mortars photographed through the microscope (shown in Fig. 3), the grains of sand show as large as boulders and each has a well-defined shadow. Further, since only cement and a sand of known size were used in the briquette, the "rocks" between the boulders can be nothing other than cement; and this cement must be unhydrated, since its color by direct vision, varying from light green to dark brown, and its resistance to the cutting of the polishing powders used in preparing the surface to remove the portion known to be hydrated, both testify to the same fact.

Such disclosures as these were the basis on which was undertaken the original research by the author, of which this Industrial Fellowship research was a later outgrowth. Since such structures were found to be typical of all mortars examined, and since cement is the most variable constituent of any mortar or any concrete, it was argued that any process which would insure thorough hydration of the

cement particles would render possible the use either of higher unit-stress values, or of less cement for present allowable values, with a most pronounced saving in either case, both in materials and money.

From the nature of this investigation, it is at once evident that progress would have to be measured by checking values obtained by the apparatus against those obtained with the same materials under standard conditions of mixing and moulding. In addition to the standard physical tests, it was also proposed to carry on a study of the micro-sections of each set of specimens broken. To facilitate such a comparative study, record books were prepared for both hand and machine mixes, the hand mixes being designated by the letter *H*, followed by a serial number, with results recorded below; and the same data for machine mixes, design-

FIG. 1 IMPROVED FORM OF HYDRATOR

ated by the letter *P* (pneumatic) followed by a serial number, are placed on the opposite page. The position of the break of each briquette was recorded in the outline form. Although not recommended for general use, this has proved of very great benefit in reconciling otherwise discordant results.

In Fig. 1 is shown one of the latest forms of hydrator used, which was believed to include the essential features of earlier types with the mechanically troublesome parts refined. In this photograph, *A* is a hopper, of sufficient size to contain a whole bag of cement; *B* is the atomizer, with the jets increased to forty-eight; *C* is a feed-device of coffee-mill type, driven by an electric motor; and *D* is a container with baffled exits. In spite of the fondest hopes and the most strenuous labor, this machine failed in its purpose, so far as really notable results are concerned. As the re-

the original, as in Fig. 7, this is made even more apparent; carrying it to 20 times the original, by means of photographing through the microscope, shows, as in Fig. 8, that all the aggregate in sight are sand grains of greater or less size, separated, as were the pieces of stone, and with still finer particles, too small to be sand, lying between them. Magnifying this same field to 60 times the actual diameter, as in Fig. 9, shows the sand grains in increased size, with a relative increase in their mutual dispersion; and a peculiar honeycomb structure on the smaller particles lying between them. Magnifying a portion of this same field 200 times, as in Fig. 10, this honeycomb structure is revealed more definitely. Since elimination of stone and sand from the known composition of the concrete indicates this honeycombed particle to be unhydrated cement and as similar formations occur profusely throughout all concretes, it becomes important to identify them beyond question and to study their functions in the rigid concrete mass, for, if they are unhydrated cement, lying inert, they have a most important bearing on the strength of concrete.

The easiest identification is offered by comparison between the known and unknown material. In Fig. 11 is shown the structure of a neat cement briquette as viewed through the microscope at a magnification of 60 diameters. Comparing this with Fig. 9, which has the same degree of magnification, the identity of the two materials is strongly indicated. But to make this more certain, in Fig. 12 is shown the central portion of Fig. 11 but at a magnification of 200 diameters. Comparing this with Fig. 10, which shows the unknown material found in the concrete, their general characteristics are seen to be identical.

In an early paragraph of this paper, the proportion of material in standard sand mortar, which was then stated to be unhydrated cement, was seen to be large. In view of what has just been demonstrated, the truth of this statement is not difficult of proof. In Fig. 13 is shown a section of surface of a standard sand briquette, photographed at a magnification of 200 diameters. The structure of the cement group is here shown in an increased size, with the segmental edges of grains of standard sand, in its near neighborhood. Since in this briquette no materials other than cement, standard sand and water were used, the photograph serves as further proof of the identity of the questioned structure.

It may be objected, however, that this particle is too large to be a cement particle, and that if it were a group of cement particles, they would hydrate and fall apart. To answer this objection, recourse must be had to a consideration of the physical actions involved in wetting dry cement with water.

In Fig. 14 is shown at a magnification of 30 diameters the appearance of dry cement as it lies on a microscope slide. This cement film is very thin, a mere surface dust, but it will be seen that the distribution is very uniform. But if water is added, quite different conditions obtain. In Fig. 15, the water may be seen progressing across the field. Where the water is, there is not, as might be expected, a uniform wetting of the dry powder, but instead, the fine material is grouped in masses of varying size, and it is plain that some extraneous force would be required to break up these masses, since they evidently are in their present positions in obedience to the action of certain forces which have moved the particles from their original place.

The truth of this is easily demonstrable. Surface tension—that peculiar chain of action and interaction which causes rain drops to assume the spherical form—gathers the particles together in groups; and the finer they are, the more easily are they affected. The fineness of cement particles is, in this respect, a detriment to efficient hydration.

But in the process of this grouping, the particles have become slightly wetted. This has immediately resulted in reactions with the cement; and as the quantity of water is necessarily limited by the close grouping of these fine particles, a saturated solution between them, with deposition therefrom of the interlacing crystals before noted, has speedily resulted. In far shorter time, therefore, than is required for initial set under usual conditions, these little groups of particles have become consolidated; and unless the mechanical agitation of mixing is sufficient to break down this crystalline bond, they will remain unhydrated, save at their outer surfaces, so long as the concrete endures. This condition of affairs is difficult to overcome, even by the mechanical action of mixing, as the very small size of the groups renders unlikely their physical dispersion by the agitation of relatively large materials such as sand or stone, which by reason of the water present, are out of contact with one another. This is partially true regardless of the extent to which the process is prolonged. Further, the bond between these particles is speedily rendered more secure by secondary colloidal formations, with their desiccation by absorption of water by the interior of the mass. These colloidal boundary and bonding masses form the honeycomb structure seen in the photograph. Their appearance as white boundaries in some slides and dark boundaries in others is due to the method of polish-attack used in developing the surface prior to its examination.

This grouping and quick-cementing action, therefore, is the reason that the experimental apparatus developed proved inadequate for the task. This is particularly true of later forms, for in them the number of atomizing jets was increased to such an extent that the fine drops, though initially of a size suited to an individual cement particle, were in such numbers as to coalesce; and the larger drops thus formed caused, by surface tension, grouping of cement particles, such as has been shown. It is evident that means other than those at first proposed are required to produce effective hydration.

With a view to ascertaining the results produced by field conditions, as distinguished from the laboratory-made specimens which have thus far been examined, sections of a few concretes obtained from actual construction were examined. A large number of specimens of concretes were collected from representative structures throughout the world; and the author desires to take the opportunity here presented of extending personal thanks to the many engineers who have been so kind as to supply the samples asked for. Without their aid, the scope of this research would have been much restricted.

Examination of these specimens shows that similar conditions exist throughout the entire mass of each and since none of the specimens is over 1 cu. in. in volume, the quantity of cement remaining unhydrated through such grouping in each cu. yd. of concrete is a matter to ponder upon. It is easy to extend like illustrations to a far greater length with the data already at hand, but the series above given covers a wide range of classes of concrete of varying ages

and conditions of service, and made under widely different conditions. *Grouping of particles in the manner indicated is a characteristic of all concretes so far examined;* and because of this grouping and of actions next to be indicated, it seems probable that only a small percentage of the cement added to concrete is effectively used.

Obviously, it is of the greatest importance that this grouping and isolation of large masses should be prevented. But even if this were quite perfectly done, there remain other actions which militate against thoroughly efficient hydration.

In microscopic examination of concretes, one of the most notable features of the hydrated matrix, aside from the large masses remaining unhydrated, is a "mealy" or speckled appearance. An example of this is shown at 60 diameters in Fig. 16 (concrete from pile caps underwater, Staten Island Ferry, Battery Park, New York). Such a surface is very difficult to photograph and was obtained only by the most delicate polishing. The mealy, or spotty, appearance is here clearly shown, and by careful examination, it can be determined that each of these spots is a cement particle, covered over with a colloidal, or perhaps a colloidal-and-crystalline skin, but remaining quite unhydrated at its center.

The reasons for these conditions are made clear by a consideration of the phenomena of hydration as before given, together with the absorption of water by the particle as hydration proceeds and the formation of an impermeable covering by the desiccation of this colloid through abstraction of water from the outer layers by the inner. Further, even with free access of water to the outside of a particle these conditions obtain, for in an agitated mass of cement in spite of the profuse formation of flocculent colloids, an unhydrated center has yet been found in each of the particles examined.

Therefore, it is evident that the finer the grinding, the better will be the hydration, as the finer the particle, the greater its surface in proportion to its bulk and in consequence, the more ready the penetration of reactive water. On the other hand, the finer the particles, the more ready and the closer will be their grouping by surface tension of the mixing water unless means can be found to lower this surface tension, without harmfully affecting the quality or the cost of the concrete.

The importance of increasing hydration cannot be exaggerated. Even a slight increase in thickness of hydrated layer results in notable increase in strength. In the earlier, though limited, investigations of this research when cement was delivered by an air-boil, to be met by finely atomized water under the best conditions for union, tensile and compressive strengths rose to high values, with a further peculiarity that the cement showed no retrogression with passage of time. Micro-sections also confirmed physical tests as to the progress of hydration, so that high hopes were entertained for commercial success along similar lines.

But since the conditions revealed by this research have become known and their causes have been ascertained, the next step is the overcoming of objectionable features by removing the causes of their origin. In other words, if high surface tension is at fault, to promote hydration lower that factor to a value which will not be disadvantageous. There are several substances which will lower the surface tension of water. One of these is alcohol, and the effect of additions of alcohol to the mixing water of cement may be

readily investigated with the assistance of the microscope.

In Fig. 17 is shown the effect of adding water to this cement. As can readily be seen, the particles have grouped themselves in aggregations of varying size, in formations similar to those found in the examination of set concretes. But if to this water is added a small percentage of alcohol, dispersion immediately results, as in Fig. 18. Although the dispersion here is not complete, the cement is in vastly better situation to be effectively hydrated than it was when closely grouped, before the deflocculent (alcohol) was added.

In commercial work it is of course impracticable to use alcohol in sufficient quantities to properly promote hydration, nor would its use be beneficial to the concrete, because of the excessive liquid content thus made necessary to allow for the evaporation of the alcohol. But there are other agents even more efficient, which are cheap and easy to use and have no objectionable chemical action. So far as experiments have been carried out, these substances promise to produce concrete of greater density and strength than has heretofore been possible.

There are, however, certain other ordinary though important factors in the making of concrete which may be considered briefly. These are: *a* thorough mixing; *b* proper proportioning of aggregates; *c* proper consistency.

Thorough mixing is one of the most potent factors in securing thorough distribution of cement, thorough contact of cement paste with aggregate, and also, to a certain extent, hydration. Water does not necessarily wet aggregates instantly, for a reluctance or "skin effect" retards its passage over the surfaces of dissimilar materials. Further, this film of water on a piece of stone, for instance, or a particle of sand, holds beneath it air bubbles, which may in some instances be so numerous as to constitute an entire air-skin about the particle of aggregate, preventing contact between the cement and the sand or stone, unless mechanical agitation, with scraping by adjacent particles, is prolonged for a time sufficient to break down such films. Further, besides the smaller lumps and groups of cement particles caused by surface tension, there are commonly very large lumps of compacted cement in the sacks, and it often requires as much agitation to pulverize these lumps as it does to distribute the finer portions throughout the mix. A poor quality of concrete should not always be considered due to the cement, the aggregate or the water used, unless it is certain that proper mixing has been secured.

The proper selection and proportioning of aggregates is also of great importance. It has been pointed out above that void determinations were quite unreliable as a basis of proportioning, since the aggregates in the set concretes are all in far more dispersed positions, relative to one another, than they were when void tests were made. It is axiomatic that a concrete, which in density most nearly approaches the density of its large aggregate, is the strongest and best. Further, the smaller the amount of cement in a concrete, consistent with proper void-filling and proper bonding of aggregates, the better should be the concrete, since cement is the weakest of all the ingredients. For any given materials therefore the proportions should be determined in such ratio that maximum density will result, and if these proportions are adhered to in the field, a very superior concrete should be produced.

The question of consistency of mix is one which is closely related to the size and grading of aggregates. Obviously, a

FIG. 26

fine sand, which has greater surface area than a coarse sand, will require more water for a given consistency of mortar than would the latter. Similarly a graded sand having less voids will require less water than would sand in which all the particles are of one size, and the same remarks apply to the larger aggregate as well. Excessive water may further occasion shrinkage cracks in the matrix. Some of these may be so large as to be visible to the naked eye, but others whose existence is rarely suspected are rendered visi-

forms, or to bond with the steel. Eternal vigilance in these details is one of the requirements for success.

There have been in the past certain cases of failure of concretes exposed to sea-water, which have become very widely known. It is probable that to no one phase of the concrete industry has so much thought and labor been devoted as to the study of the behavior of concretes in sea-water and the production of a cement capable of withstanding their action. There is considerable disagreement among authorities as to the causes of such disintegration, but there seems to be concurrence in the opinion that the formation of calcium sulpho-aluminate by interaction between the sulphates of sea-water and the aluminates of the cement, is in large measure responsible. This salt (calcium sulpho-alum-

FIG. 27

FIG. 29

FIG. 28

ble only by microscopic examination. Fig. 19 shows a three-branched shrinkage crack of this kind. If proper tests of materials are made, the correct proportion of water may be determined, as well as the proportions of the ingredients; and if proper supervision is maintained in the field so that these quantities are adhered to, there need be little fear of producing a concrete which will develop faults as it dries, of "drowning" the cement, or of failure properly to fill

inate) increases largely in bulk by crystallization and disrupts the concrete by the physical actions attendant thereon.

If we were to picture mentally the formation of such an expansive material in the cement matrix of a set concrete, we should have to imagine a gradual straining of the material confining the crystals until rupture occurred. It is significant as to the correctness of such an hypothesis, that in the matrix of concretes which show outward signs of disintegration are found by microscopic study interior evidences of such strain.

In babbitts and the softer bronzes, incipient fracture is indicated by "shear planes" or "slip bands." In Fig. 20 at 150 diameters are shown similar "shear planes" in the cement matrix of a sea-water concrete taken from New York Harbor. It will be observed that these shear planes are at right angles to the polish-scratches on the specimen, so that their lack of identity cannot be questioned. Further, this is not an isolated case, since the same characteristic features are found in many other specimens taken from concretes in similar situations. Fig. 21 shows a repetition of these general features, as do also Figs. 22 and 23 all at 150 diameters. Other examples of the same structures could be readily furnished, but these four should be sufficient to establish the fact of their nature and existence.

Various stages of such crystalline disruptions, indicative at least of the possibility of such action, are detected by further micro-examination. In Fig. 24 at 200 diameters are seen a pair of parallel shear planes which have evidently progressed beyond the stage of strain and become actual fractures filled with crystalline material, as may be determined by their having withstood the abrasive action of the polishing powders, which cut away the softer matrix surrounding, leaving these fillings in high relief. In Fig. 25 at 200 diameters is shown a similar formation, with a large group of unhydrated cement particles near by. Fig. 26 shows at 150 diameters a similar conjunction of crystalline filling of slip planes and an unhydrated group. Whether or not this conjunction is of significance is a point yet to be fully determined.

Under certain conditions also this crystalline disruptive action may affect a considerable area. In Fig. 27 is shown at a magnification of 60 diameters part of such an extended action, where the crystalline formation is a long, disruptive dike. This structure resolved at higher magnification (200 diameters) is shown in Figs. 28 and 29, and this particular dike is of special interest in that it lies in a sample of a fresh-water concrete 12 years old, which is now showing pronounced outward signs of disintegration. It is greatly to be regretted that these dikes are so minute as to render their isolation and chemical analysis almost impossible. Such an analysis would be of great value in deciding many questions which at present seem to defy solution.

But whether or not calcium sulpho-aluminate is the major factor in disruptive formations in concrete, there seems to be agreement among cement experts that advantageous changes could be made in the chemical composition of cements, especially where they are to be used for sea-water concrete. A reduction in the alumina content would be beneficial in this respect, though it would entail serious difficulties in manufacture due to the higher temperatures required in burning the clinker. The addition in grinding of pozzolaine material, in order to obtain silica in a condition chemically available for union with the calcium hydrate liberated in the setting reactions, seems also to have much to recommend it. This latter change we should expect to prove very beneficial, for the leaching of calcium hydrate from cement structures which are subjected to the percolation of water is well known. Any such removal of material must necessarily leave a corresponding void suited to the reception of perhaps deleterious crystalline material, such as forms the dikes above noted.

There has recently been published a very exhaustive research, by Rankine and Shepherd¹ of the Geophysical Laboratory at Washington, on the products formed by the sintering of varying proportions of the three radicals, CaO , Al_2O_3 and SiO_2 , which are the essential constituents of Portland cement. A portion of this three-component diagram, taken from the Rankine and Shepherd diagram and sketched with approximate correctness, is shown in Fig. 2.

In interpreting this diagram it should be noted that the lime content increases vertically, the percentage being read on the parallel horizontal lines. The percentage of alumina (Al_2O_3) increases downward at the right, the alumina content being read on the lines slanting downward from right to left. The silica content similarly increases downward but at the left, the percentage of silica for any mixture being read on the lines sloping from right to left. The

heavy dotted lines indicate the loci of eutectic mixture, and the light dotted lines the approximate isotherms. It is evident from these that as the mixture under fusion changes its proportion of any of the three ingredients, the sintering temperature also changes; and, conversely, if the constitution of any mixture is known, the temperature required for its formation may also be determined.

For instance, the temperature commonly employed in burning Portland cement is in the neighborhood of 1500 deg. cent. This would be the proper sintering temperature of a mixture somewhere in the neighborhood of *D*, where the composition called for would be approximately 37.5 per cent of alumina, 6.5 per cent of silica and 56 per cent of lime. But the region of Portland cements is in the neighborhood of the point *A*, at which the indicated proportions would be alumina 9.66 per cent, silica 23.41 per cent and lime 66.93 per cent. For the proper formation of this latter compound a temperature of about 1900 deg. cent. would be required. As 1600 deg. cent. is the melting temperature of steel, and 1500 deg. cent. the usual kiln temperature, it is evident that in the burning of Portland cement, the natural tendency is to obtain a product unduly rich in alumina and low in silica and lime, so that the formation of the proper compounds is left largely to chance; and oftentimes unduly large proportions of Al_2O_3 are carried over, which, as was before noted, is generally held to be responsible for such disintegration of sea-water concretes as has been observed. This is a phase of the sea-water question in the solving of which the user can do little except demand a material of the quality he desires. Cement manufacturers are, however,earing for this question as adequately as commercial conditions will permit.

The above diagram, which is based on the tertiary alloy diagram of the late Dr. R. H. Thurston, is due to Prof. George B. Upton, of Sibley College, Cornell University. To him also is due the interesting transformation of chemical equations by reduction of certain elements to simpler equivalents, which does much to clear away the fog caused by the complex composition of cements and which further shows, by the same means, that the various cements, whether Portland, natural or iron-ore-Portland, have essentially the same actions as the basis of their setting properties. The location of these cements on the diagram are shown at *A* for standard Portland, *B* for the iron-ore-Portland used in the Panama Canal, and *C* for an American natural cement.

DISCUSSION

JOHN R. FREEMAN considered the paper, while excellently setting forth advanced methods in microscopic analysis of Portland cement mortar, gave simply a diagnosis of some of the most important diseases to which cement work is subject, without yet giving the remedy.

He looked upon the matter of applying the methods of micro-petrography and micro-metallurgy to concrete as nothing less than epoch-making and considered that the recent studies made by the author and by certain other microscopists gave great promise of extremely important benefits. Yet so far as these studies were reported, he regarded them merely as an excellent beginning of a more precise, profound and intimate study of this most important building material, which should be encouraged by engineers and by cement manufacturers and carried very much further.

This paper considers chiefly the methods of microscopic

¹ *Am. Journal of Science*, Jan., 1914.

study of voids and lack of hydration. Another investigator has made a good beginning on studies of a soluble content of the cement, but it is no less important that the study should be continued into the realms of micro-physics and colloidal-chemistry, if one would learn the cause of some of the occasional serious failures in the strength of concrete and its slow disintegration by water and frost.

He had no doubt that ten years from now following studies of this kind, a better grade of concrete would be made and that some cement made by recent rapid and cheap methods and acceptable under present standard specifications would come to be regarded as doubtful if not dangerous, for portland cement is by no means a simple uniform material and different brands and perhaps different batches of the same brand are far from being alike and perhaps differ in very important particulars from the cement made ten, twenty or fifty years ago with which the reputation of Portland cement as a permanent water-resisting and frost-resisting material was established.

He recalled the great change that had come about within his experience of the past thirty or forty years in mixing and depositing Portland cement concrete; that the standard methods of distributing and depositing concrete in a sloppy condition which are standard today would not have been tolerated by any respectable engineer years ago in the days when standard practice was that of mixing concrete by shovels on a mortar bed, turning it over two or three times and depositing it in a mealy, slightly moist condition in thin layers and carefully ramming it until water flushed to its surface. Today the mixing by rotary machines surely is far more thorough and better than the old hand-mixing and this improvement doubtless more than compensates for the possible injury from excess of water in the modern method as compared with the old.

While nearly everyone knows of this great change in methods of mixing and depositing concrete, there are not many who fully appreciate the great change that has taken place within the past few years in methods of making cement in virtually a single operation under intense heat in rotary kilns, and we cannot yet be sure that the cement concrete put down today will all of it prove as durable as most of that made with the old-fashioned cement and deposited by the old-fashioned methods.

Microscopical studies like those presented in this paper will do much toward finding out how to improve the character of the cement and how to improve the quality of concrete, and today give more promise than any other line of investigation, but the studies must be carried much beyond the scope of those outlined in the present paper and the most refined processes of physical chemistry called in to aid.

The speaker suggested two matters of special importance which needed further study:

- (1) That of the possible solubility of some of the ultimate compounds resulting from the setting of the modern cements, whereby structures having thin sections would in course of time lose much of the strength on which their integrity depends.
- (2) The effect of obscure chemical properties in good-looking sand which might seriously affect the strength of the mortar.

To illustrate these matters he cited a few tests made, incidental to other work, in the laboratory of the New York Board of Water Supply and which suggested this danger

of dissolving out and loss of the strength-giving quality in thin sections of concrete of somewhat pervious or lean quality. These tests were a few made primarily to determine whether or not aggregates containing certain varieties of limestone were soluble, but in the series were specimens made up for control purposes with aggregates essentially insoluble. Croton water under about 40 pounds pressure was made to percolate very slowly through disks some 4 or 5 in. in diameter by 10 or 12 in. broad for a number of months and the filtrate caught and subjected to chemical analysis, with the result that it appeared that more of the cement than of the aggregate was being dissolved. At the close of this test a few of the disks were tested for compressive strength with the surprising result that they possessed, as the speaker remembered it, less than one-fourth of the strength of similar disks which had not been subjected to this slow percolation. These experiments were not followed up because of lack of time and pressure of other work, but they give much food for thought, and it would seem that, after all this percolation, the cement in these specimens must have been hydrated and thus free from one important defect found by the author in most of his specimens.

The speaker recently has been shown the results of an investigation of disintegration of concrete which seemed to clearly indicate that the cement was partially dissolved out near the surface after a few years exposure to water and that the action of frost on the slightly porous mass remaining caused its breaking down.

Upon the second topic, of obscure chemical properties, and as illustrating the need of supplementing the microscopic studies by some researches in colloidal chemistry or by researches advanced into the realms of physical chemistry, he cited some troubles that he encountered three or four years ago when planning a concrete dam. Close to the site he found what seemed to be a perfect mixture of gravel and sand, well graded and apparently clean and requiring simply to be mixed with cement and water in order to give excellent concrete, but on sending samples of this material to the laboratory for mechanical analysis and test of mortar it was found that the mortar made from this sand would not stand up sufficiently to be held in the clamps of a testing machine after setting 7 days, and after setting for 28 days it gave a strength less than one-fifth of the normal when tested with four or five different brands of cement; yet one particular brand of cement was found which gave a fairly strong mortar with this same sand, thus proving that the trouble was to be looked for in the sand rather than in the cement, but no reason has yet been found why this one particular make of cement worked so very differently with this peculiar sand.

After washing this sand in a way intended to cause mutual attrition and scrubbing of the individual grains, it was found to give tolerably strong mortar with all these brands of cement, and on analyzing the wash water by methods used for drinking water the reports showed a large percentage of albuminoid ammonia. An expert of the U. S. Department of Agriculture, who had spent much time on studies of the solubility of the mineral ingredients of different soils, suggested to the speaker that the peculiar behavior of this sand in relation to Portland cement was probably due to a low, complex organic acid, akin to tannic acid, which was present in a condition of *adsorption* on the outside of the sand grains and that to find out what was

worth knowing about this action might keep a skilled research chemist busy for a year.¹

It is certain that some concrete has withstood frost and the wear of rapid currents of water for many years marvelously well. On the other hand, it is certain that some concrete from cement made by rapid modern methods, under rigid specifications and conscientious inspections, has gone to pieces in a most distressing way. It is possible that some of the modern concrete put down with a super-abundance of water, and perhaps some that is made with cement containing ingredients leading to compounds that will ultimately become soluble, may bring disaster when concrete is used in thin sections under high water pressure and expected to retain its normal strength indefinitely.

The subject is extremely important and engineers should be grateful for all contributions to it like the present paper and should be pleased to note that while the author now simply gives his method of diagnosis, he implies that in a future paper a remedy for some of the present troubles will be presented.

FRANK B. GILBRETH said that his first experience with Portland cement was in 1885, when cement practice was entirely different (from a workman's standpoint) from what it is to-day. In those days any man that used Portland cement on the first set was considered an ignoramus; to-day any man that uses it on the second set is considered a fool.

This work on the chemistry of cement is of tremendous importance to the country. What we are going to do with cement in the next few years as compared with what we have done will be of tremendous value in the structural world.

He had specialized in concrete, not in the chemistry of it but in its utilization, and in the latter connection he gave some of his experiences.

He was once building a hotel in San Francisco, and the reinforced concrete columns and girders were built up to the second floor, and the rest of the building was proceeded with, but the concrete did not set—and had not done so for eight weeks. Forms were taken out in a few places to see whether air was required to dry it out, but without effect. Just as it seemed that the concrete work must all be taken down, the San Francisco earthquake occurred, and the day after the concrete was found to be set. Whether it happened that the earthquake caused the setting or no, the fact is exactly as stated.

We are not sure but the atoms that make up the molecules in concrete might possibly require a physical start to cause the material to set. Several times the setting of concrete that has been delayed has been known to be started by machinery being run in the vicinity, and it is well known that if air riveters are working on the forms of concrete when the latter is being poured, a quicker set is obtained than at another time.

F. H. NEWELL also related an experience in connection with concrete refusing to set. The Board of Engineers had set up some concrete work at a large expense to the Government, and then reported that the concrete did not set and must be taken out. By the time the report was issued, the piers which were officially condemned as worthless had set as hard as granite.

In reference to the fineness of the cement, he thought it is

generally recognized that fine cement is so much better than coarse cement such as that which stays at the top of a 200 mesh sieve, and which has very little cementing value. Such cement ground up and passed through a 200 mesh sieve and made into little test pieces had been found to break at 600 lb. per sq. in.; reground, passed through the 200 mesh sieve and set up again, test pieces broke at perhaps 300 lb. per sq. in. Reground a third time and set up, pieces broke at about 200 lb. This illustrates the point that the regrounding of the cement, bringing the minute particles into immediate contact, enables it to set up again, and apparently indicates that we are not getting the full cementing value from our concrete as ordinarily used. He thought this point is one worthy of a good deal of investigation.

G. A. RANKIN² (written): This paper is very interesting and instructive in so far as it gives a large amount of data on the mechanical hydration of Portland cement and the disintegration of concrete in sea water. The discussion of the components of cement CaO , Al_2O_3 , SiO_2 , Fe_2O_3 and MgO , is, however, open to criticism.

The statement that if the constitution of any mixture is known, the temperature required for its formation may also be determined, is not true. The temperatures given in Fig. 2 are temperatures of complete melting and not temperatures required for the formation of compounds. In fact, it cannot be said that there are any definite temperatures for the formation of the compounds which go to make up Portland cement, as the formation depends on the time of heating and the fineness of the raw material, as well as the temperature. If sufficient time is allowed, it is possible to form these compounds even at temperatures much below that at which melting begins in a given texture. In actual cement practice, however, the temperature of burning is sufficiently high so that a small amount of the clinker is melted. This is necessary, as a small amount of melted material acting as a flux is required in order that the formation of compounds may be completed within a reasonable time. The temperature of the clinkering zone as determined by the Geophysical Laboratory in a number of Portland cement kilns was found to be about 1425 deg. cent. At this temperature only a small portion of the clinker is fused (melted); even so, it is sufficient for the proper formation of the compounds if the raw material is of a fineness such as is ordinarily required in good cement practice; in other words, the reactions which take place in the burning of Portland cement clinker go practically to completion even at a temperature of about 1425 deg. cent. The statement that the formation of the proper compounds is left largely to chance and that oftentimes unduly large proportions of Al_2O_3 are carried over is not true of good cement practice. In such practice it is possible to so control the raw material and conditions of burning that the resulting cement will be made up of proper compounds in such proportions that no improperly combined Al_2O_3 will be present. As to whether or not it is the compounds of Al_2O_3 which react with sea-water to cause the disruption of concrete is another matter, which it should be possible to settle by determining the action of sea-water on cements made up of the two aluminates, 3CaO , Al_2O_3 , and 5CaO , $3\text{Al}_2\text{O}_3$, which occur in Portland cement. The idea that CaO and MgO and likewise Al_2O_3 and Fe_2O_3 act similarly

¹ See Eng. News, July, 1912, contribution by J. R. F.

² Geophysical Laboratory, Washington, D. C.

in hydraulic cements and form similar chemical compounds is erroneous. Recent investigations have shown that MgO and CaO , likewise Al_2O_3 and Fe_2O_3 do not act chemically alike, either in the reactions which take place in the burning of cement or in those which take place during hydration. For example, CaO unites with Al_2O_3 in the formation of four distinct compounds, while MgO unites with Al_2O_3 to form but a single compound whose properties are not similar to the calcium aluminates. Again, Fe_2O_3 and Al_2O_3 , as they occur in cement compounds, react with water very differently, the ferrates being slow to act while the aluminates react with great rapidity, and the final products of hydration have decidedly different properties. It will be seen, therefore, that speculation which assumes the reactions between the chemical components of Portland cement, based on any two or more of these components acting as chemical equivalents, may lead to disastrous results.

In order to establish a sound basis for the study of Portland cement and its use in concrete, it is absolutely necessary that one proceed systematically to determine first the components which make up the cement. These are CaO , Al_2O_3 , SiO_2 , MgO , Fe_2O_3 , etc.

Knowing the components, the next step is to determine by experiment the compounds formed by these components in the proportions as they occur in cement. Having isolated each of these compounds to determine its composition and its optical properties for its certain identification, it will then be necessary to study its hydraulic properties. With this data it will be possible to state definitely just what is the nature of the setting of cements, also to state just what compounds should be present in order to produce the strongest cement and what compounds are best to withstand action of sea-water, etc.

Proceeding in this systematic way, work has been carried on at the Geophysical Laboratory in an effort to determine the compounds formed by the components which make up Portland cement clinker. Since the components CaO , Al_2O_3 , SiO_2 make up over 90 per cent of the chemical composition of most Portland cement, it seemed best to first make a study of these three oxides by themselves. The result of this investigation has shown that when CaO , Al_2O_3 , SiO_2 are burned in the proportions as they occur in Portland cement clinker, the resulting product is made up largely of the compounds $3CaO.SiO_2$; $2CaO.SiO_2$; $3CaO.Al_2O_3$, with occasionally small amounts of free CaO and the compound $CaO.3Al_2O_3$. Each of these compounds has definite optical properties which have been determined; this enables one to identify these compounds in any mixture in which they may occur.

The cement clinker made up only of CaO , Al_2O_3 , SiO_2 on grinding and mixing with water has been found to possess all the properties of a desirable Portland cement. It has furthermore been found by subsequent work of the Bureau of Standards at Pittsburgh, that over 90 per cent of an average Portland cement clinker is made up of $3CaO.SiO_2$; $2CaO.SiO_2$; $3CaO.Al_2O_3$; and $5CaO.3Al_2O_3$. These compounds are present as definite individual crystals whose optical characteristics are not appreciably affected by the small amount of MgO , Fe_2O_3 , etc., which are always present in Portland cement. A study of the hydration of those compounds was undertaken by the Pittsburgh Laboratory of the Bureau of Standards, and from the results obtained it is now possible to explain the chemical reactions which take place during the setting of Portland cement. With these added data it is now

possible to proceed with confidence to the determination of the proportions of these CaO , Al_2O_3 , SiO_2 compounds which should be present in order to produce a cement which on setting will possess the most desirable properties for various purposes.

HARRY FRANKLIN PORTER¹ wrote that Mr. Johnson has established, by laboratory methods, conclusions which the writer believed since 1908, that the true cement is a colloid produced by thorough hydration. A special article dealing with this important subject, based largely on the findings of Dr. Michaelis, was inserted in an appendix to a publication by the writer the following year.

Further, at the 1910 convention of the American Concrete Institute, the writer again devoted a considerable portion of a paper to a discussion of this subject, recounting an experience in Philadelphia several years previous, in which the value of thorough mixing of concrete as promoting colloidal formation was conclusively demonstrated.

This experience was that a certain batch of concrete, supposedly useless on account of having been churned in the mixer during the whole of the noon hour, was dumped on concrete poured the previous day. Instead of becoming a loose mass of rock and sand, as expected, it set up smooth and hard and adhered so firmly to the old concrete as to require picking to remove it. Moreover, it presented a different appearance than any concrete the writer had seen before and was much more uniform in color and texture. The exceptionally thorough mixing, and the unintentional thorough hydration, instead of weakening it seemed to have vastly improved its quality.

In concrete work, there is necessity for, first, intelligent selection of the aggregates; second, their scientific proportioning; and third, their thorough admixture. If the proper care is taken in these matters, not only is a considerably less amount of cement sufficient, but a concrete of vastly superior quality and strength is secured.

THE AUTHOR. The comment most frequently met with in regard to this microscopic study of concretes is that it does not indicate a remedy for the defects shown. Microscopic examination is primarily a diagnosis. It shows concretes as they actually are, not as they are supposed to be; and the faults that careless procedure and improper selection of materials induce. Further, the inter-relation and the inter-action of the several materials composing concrete are made plain, together with the penalties attendant upon any neglect of these inter-relations.

The remedy lies very largely in alterations of our present procedure. It is very true that there are certain beneficial changes that might be made in the cement, which is not by any means an ideal product, but it is true, also, that more care should be used in the selection and particularly in the quantities of the other constituents used. When the concrete maker realizes that the quantities and gradings of his stone and especially of his sand are vitally important and when he also realizes that the quantity of water may not be varied beyond certain limits, we may hope to see a very important change in the quality of concrete.

It should also be realized by engineers that concrete is not an infinitely dense, hard, resistant substance, but that, on the contrary, it is a material which varies in durability.

DESIGN OF RECTANGULAR CON- CRETE BEAMS

BY HOWARD HARDING, ROCHESTER, N. Y.

Associate-Member

THE resisting moment of a reinforced concrete beam, in inch-pounds, may be represented by the formula

$$\text{Resisting moment} = R b d^2$$

where

- b is the breadth of the beam in inches
- d is the effective depth in inches
- R is a numerical coefficient

The value of R (for a given ratio of the modulus of elasticity of steel to that of concrete) depends upon the percentage of steel reinforcement used and the safe working stresses for steel and concrete. These values of R for different working stresses and percentages of steel have been plotted in very

FIG. 1. DIAGRAM FOR CHECKING RELATIONS INDICATED BY EQUATION

convenient curve form in Turneaure and Maurer's "Principles of Reinforced Concrete."

For the purposes of this article it will be necessary to cite only a few values of R corresponding to some of the more common working stresses. The ratio of E_s to E_c is taken as 15.

For $f_c = 700$ and $f_s = 16,000$

For $f_c = 600$ and $f_s = 16,000$

For $f_c = 500$ and $f_s = 16,000$

For $f_c = 400$ and $f_s = 16,000$

$R = 120$, per cent steel = 0.87

$R = 94$, per cent steel = 0.68

$R = 71$, per cent steel = 0.50

$R = 49$, per cent steel = 0.34

In case of reinforcement in excess of the amount required to divide the working stresses as shown there is a slight gain in strength due to the shifting of the neutral axis toward the steel. When the concrete has reached its working stress the steel will still be understressed. In such cases the value of R used must be the one corresponding to the working stress of concrete and the percentage of reinforcement.

The ordinary method of using the data thus given is that of "cut and try."

After quite a bit of experience with that method the growing dissatisfaction prompted the plotting of the equations

involved so as to give a direct method of arriving at the result desired. After some study a logarithmic form was adopted which seems to serve the purpose.

On a sheet of logarithmic cross-section paper the values of b were denoted by the horizontal lines intersecting the left-hand ordinate. The left-hand ordinate was called the b scale. Through the origin (that is, through the point 1, 1 of the diagram) draw a line to the right at 45 deg. to the horizontal. By inspection of Fig. 1 it can readily be seen that the point of intersection of any value b with the oblique line, if projected vertically upward to the top horizontal scale of the paper, will give a logarithmic reading exactly equivalent to that of the b scale. Now let the oblique line correspond to $d = 10$ and multiply the readings of the top horizontal scale by 100. Then again by inspection, it will be seen that by projecting vertically upward the intersection of any value b and the line $d = 10$, we may (on the multiplied horizontal scale) read directly the corresponding value of $b d^2$.

For values of d other than 10 there is a family of lines parallel to the line $d = 10$.

It now remains to introduce the factor R into the diagram. A range of from 40 to 120 for this coefficient will be found to cover about all cases likely to arise. Since the bending moment is ordinarily computed in foot-pounds we may write our fundamental formula to correspond to those units. Then

$$\text{Resisting moment} = R \frac{b d^2}{12}$$

and when $R = 120$

$$\text{Resisting moment} = 10 b d^2$$

By projecting the values of the $b d^2$ scale upward to a horizontal scale whose readings are 10 times that of the $b d^2$ scale, we obtain directly the resisting moment in foot-pounds corresponding to any value of $b d^2$ and $R = 120$. The diagram is arranged to care for other values of R by taking the proper fractional part of the resisting moment of the beam at $R = 120$. Thus, for $R = 60$, one half of the resisting moment of the beam at $R = 120$ is taken. This is done graphically by proceeding upward to the horizontal line representing the desired value of R and thence proceeding along the oblique line to the top scale where the resisting moment in foot-pounds is read.

In the lower part of the diagram it will be noticed that there are two other families of oblique lines. One of these shows the ratio of d to b and the other the cross-sectional area or the product of d times b .

The method of using the diagram is ordinarily just the reverse of the order in which it has been developed. First decide upon the working stresses and determine the corresponding value of R and the percentage of reinforcement. Then compute the bending moment in foot-pounds which it is desired that the beam should withstand. Locate the bending moment thus computed at the top of the diagram, Fig. 2. Thence proceed parallel to the oblique lines until the value of R previously determined is intersected. From this intersection proceed vertically downward into the lower part of the diagram intersecting the horizontal lines representing breadth, and the oblique lines representing depth. At any one of these intersections the required breadth and depth may be read. Any of the corresponding values will satisfy the condition for strength, but the values chosen will depend upon the shape of beam desired. If we wish a certain

FIG. 2 DIAGRAM FOR GRAPHICALLY DETERMINING THE RESISTING MOMENTS OF REINFORCED CONCRETE BEAMS

ratio of depth to breadth we can obtain it by stopping at the dotted line representing that ratio. If a certain depth or a certain breadth is desired it is necessary to proceed vertically downward until said depth or breadth is intersected and the point of intersection automatically determines the value of the other dimension.

In a beam of dimensions as determined by the use of the diagram in Fig. 2 no allowance has been made for the bending moment of the beam due to its own dead weight. To take care of this additional bending moment either one or both of the dimensions must be increased. To determine the amount of the increase necessary for different spans and types of beams a second diagram has been developed. The strength of the beam may be increased in three different ways, viz: (a) by increasing both breadth and depth, (b) by increasing depth only, and (c) by increasing breadth only. The determination of multiplying factors for these three cases is now taken up.

The author derives the following formulae to cover these cases:

Increasing strength by increasing breadth and depth:

$$\left\{ \frac{(1.56 k^2)}{k^2 - 1} \right\} \bar{I} = R d$$

Increasing strength by increasing depth only:

$$\left\{ \frac{(1.56 k)}{k^2 - 1} \right\} \bar{I} = R d$$

Increasing strength by increasing breadth only:

$$\left\{ \frac{(1.56 k)}{k - 1} \right\} \bar{I} = R d$$

It will be noted that the form of the three expressions just developed is the same, the only variation being in the exponent of the term k enclosed in the parenthesis. A tabulation of the values of the parenthesis corresponding to different values of k is given in the paper.

To summarize the foregoing it may be well to work out a problem in detail. The writer has found the following to be a very convenient and useful form of computation:

Girders G_1	Span = 18 ft.	Load = 370 lb. per linear ft.
	Bending moment = $\frac{w l^2}{8} = \frac{370 \times 18^2}{8}$	= 15,000 ft.-lb.
	Shear = 3,330 lb. + $\frac{1}{2}$ weight of beam	
	$f_s = 16,000$ $f_c = 600$ $R = 94\% \text{ steel} = 0.68$ sq. steel rods	
	$b_1 \times d_1$	12.5 \times 12.5 9.4 \times 14.10 7.5 \times 16
	Corrector	1.17 1.145 1.136
	$b \times d$	14.6 \times 14.6 10.8 \times 16.1 8.3 \times 18.2
	$b \times d$	213 133 120
	Unit shear	25 35 37
	Steel	4 $\frac{3}{4}$ -in. bars, or 3 $\frac{9}{16}$ -in. bars, or 3 $\frac{9}{16}$ -in. bars, or 3 $\frac{11}{16}$ -in. bars 2 $\frac{11}{16}$ -in. bars 2 $\frac{11}{16}$ -in. bars

The above tabulation shows three beams which would be suitable. The one which best suits the rest of the structural design may be used. The correction factor used was the one corresponding to the increase in both dimensions. It should be noted that d represents the effective depth, and the distance from the steel reinforcing to the bottom of the beam must be added to get the total depth. This "cover" portion of the beam has been neglected in all of the computations for strength. The determination of the second beam in the tabulated form is plainly indicated on the diagrams so that the method of using them ought to be readily understood.

MODEL EXPERIMENTS AND THE FORMS OF EMPIRICAL EQUATIONS

BY EDGAR BUCKINGHAM, WASHINGTON, D. C.

Member of the Society

THE purpose of the paper is to illustrate, by application to a few problems in technical physics, the methods by which dimensional reasoning may be made use of in planning and interpreting experiments, in devising empirical equations for use in design, and especially in the performance of experiments on models in such a way as to furnish reliable information about the full-sized originals.

The General Theorem. The well known principle of the dimensional homogeneity of physical equations may be expressed in the form of an algebraic theorem which is convenient for application. This will be referred to as "the Π -theorem"; it states that any relation which involves n physical quantities of different kinds, may be described by an equation of the form

$$f(\Pi_1, \Pi_2, \dots, \Pi_{n-k}) = 0,$$

in which k is the number of fundamental units needed, and the Π 's are dimensionless products of powers of the symbols which represent the various physical quantities involved in the relation. The value of k is generally 3 in mechanical problems, though in statics $k = 2$. In the most general problems, involving thermal and electromagnetic, as well as mechanical quantities, $k = 5$.

To avoid delay at this point, the deduction of the Π theorem is relegated to an appendix.

The Flow of Liquids in Smooth Pipes. The mechanism of applying the Π -theorem in a concrete instance is illustrated in this familiar example, and it is shown that any correct equation for representing the flow of an incompressible fluid through a smooth pipe must be of the form

$$\frac{D G}{\rho S^2} = \phi \frac{D S_2}{\mu}$$

in which: D = diameter; G = pressure gradient; S = speed of flow; ρ = density of the liquid; μ = viscosity of the liquid; and ϕ represents an unknown function of $\frac{D S_2}{\mu}$ which

must be determined empirically. Comparison with the best experimental data confirms the conclusion, and the plotting of a diagram, in which English and metric data are used indiscriminately and without conversion, illustrates the convenience of working with dimensionless quantities. The comparison of the above equation with the known facts helps us to a physical understanding of the phenomena of stream line and turbulent flow—especially the existence of a critical speed and the unimportance of temperature at high speeds or in large pipes.

Resistance of Immersed Bodies at Moderate Speeds. A "moderate" speed is one far enough below that of sound in the medium, that the compressibility of the medium has no sensible effect on the resistance encountered by a moving body. The Π -theorem is used in finding the necessary general form of empirical equations between the resistance, speed, size, and shape of the body, and the properties of the

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion; price 15 cents to members; 30 cents to non-members.

medium. Consideration of the general equation and of the experimental work needed for determining its specific form, leads to the notion of model experiments and to the conceptions of corresponding speeds and of dynamical similarity. This explains the justification of the method of determining data on air-ship forms by the use of very small scale models in water.

Resistance to the Flight of Projectiles. This section shows how the conclusions reached in the preceding one must be supplemented and modified when the speed approaches or surpasses that of sound and the resistance is increased by the continual drain of energy in maintaining the head and base waves. Model experiments in air are impracticable, but the interesting possibility suggests itself that information about the resistance of large projectiles might be obtained from observations on the retardation of very small models—to a

scale of about $\frac{1}{60}$ —shot under water. A plot of observed resistances in air shows that the resistance offered to high-speed projectiles depends on density and compressibility while the effect of viscosity is negligible.

Screw Propellers. The consideration of the thrust of screw propellers illustrates an application of the Π -theorem in a more advanced case, the number of kinds of quantities to be considered being greater than in the examples already treated. The conditions for dynamical similarity of propellers of the same shape but different diameters are found, the simplest being that the propellers shall be run at the same slip ratio and the same relative immersion. The conditions can not all be exactly satisfied in practice, but it is further shown how one of the conditions, that relating to viscosity, is of small importance, and how by neglecting it, approximate results may be obtained. The condition for corresponding speeds of advance is then the same as in Froude's law of comparison, and the thrusts are proportional to the cubes of the diameters. This conclusion appears to agree with experiment, showing that the approximation made in neglecting viscosity is permissible. If propellers of a given shape are run at the same slip ratio and so deeply immersed as to cause no surface disturbance, all speeds correspond, and the thrust is proportional to $(Dn)^2$, D being the diameter and S the speed of advance.

Heat Transmission. The Π -theorem is applied to a simplified problem in heat transmission, and it is shown that while various roughly approximate relations must be assumed, the assumptions are plausible and the results obtained probably nearly correct for ordinary heat transmitting devices, such as steam coils with air forced over them for indirect heating, under working conditions. Some of the algebraic expedients which are occasionally needed in using the Π -theorem and which have not come up in any of the preceding sections, are illustrated here. The physical conclusion is that under ordinary working conditions, when a fluid is forced through a heating or cooling device of given design, the difference of temperature of the fluid and the solid surfaces at exit is a definite fraction of the difference at entrance, this fraction being fixed by the design of the apparatus and influenced in only a very minor way by the size of the apparatus, the initial difference of temperature, the nature of the fluid, or its rate of flow.

Conclusion. It is pointed out that the method of reasoning by means of dimensions is purely algebraic and therefore rigorous, so that the correctness of conclusion obtained by its

aid depends only on how much physical knowledge and common sense we display in using it, the method itself being a mere logical tool. It is, however, extremely easy of application, and it often throws a quite surprising light on experimental facts which would, without its aid, be very difficult to analyze and interpret correctly.

DISCUSSION

M. D. HERSEY. The author has struck the keynote of a new development of technical physics, which will eventually play the same part in mechanical engineering that physical chemistry has begun to play in the chemical industries. It will directly be seen that this prediction is not a prophecy at all, but merely an observation.

The importance of technical physics, as a branch of subject matter, is already so clearly recognized in Germany that laboratories are being established exclusively devoted to this field.

But the development which I think we may now anticipate is something distinct from this, and a natural sequel to it: I refer to the development of technical physics, not as a branch of subject matter, but as a method of reasoning.

It is from such a standpoint that technical physics becomes analogous to physical chemistry which is the planning and interpretation of chemical experiments in the light of thermodynamics and the phase rule; and the Π -theorem is closely analogous to thermodynamics and the phase rule. Thermodynamics affords certain rigid connecting links between seemingly isolated experimental results, while the phase rule tells us the number of degrees of freedom of a chemical system. The Π -theorem likewise affords rigid connecting links which not only serve as a check on the consistency of our results, but may greatly cut down the labor of experimenting. Thus, on applying the Π -theorem to lubrication, we find, under certain conditions, that the coefficient of friction, f , must be some function or other of the two variables $\frac{\mu n}{p}$ and $\frac{Dn}{Q}$ alone; in which μ denotes viscosity, n revolutions

per unit time, p bearing pressure, D journal diameter, and Q volume of oil pumped through bearing in unit time. Hence, the same change in f will be produced by a given change in the argument $\frac{\mu n}{p}$, whether this change is, in turn, caused by varying μ in one direction or by varying p in the other direction; and so on. These facts, all implicitly contained in the Π -theorem, can, for the sake of emphasizing our analogy, be expressed by the equations

$$\frac{\partial f}{\partial \mu} \mu = - \frac{\partial f}{\partial p} p \quad \text{whence} \quad \frac{\partial f}{\partial p} = - \frac{\mu}{p} \frac{\partial f}{\partial \mu};$$

$$\frac{\partial f}{\partial D^3} D^3 = - \frac{\partial f}{\partial Q} Q \quad \text{whence} \quad \frac{\partial f}{\partial D} = - 3 \frac{Q}{D} \frac{\partial f}{\partial Q}; \text{ etc.}$$

And, just as the phase rule tells us that the number of degrees of freedom in a chemical system is $F = K - P + 2$; K being the number of components which coexist in phases; so also the Π -theorem tells us that the number of degrees of freedom in a physical system is $f = p - k - 1$; k being the number of fundamental units needed to describe a relation subsisting among the p physical quantities. The number of factors which must be experimentally varied in order to map out the relation for the first time is, of course, one

greater than the number of degrees of freedom, or simply $p - k$.

The author has himself stated that the paper contains nothing essentially new. Any allusion to the contrary would be an impediment to the successful use of the methods presented. The kernel of the paper is a theorem which is merely a restatement of the requirements of dimensional homogeneity, announced by Fourier nearly a hundred years ago, and extensively used by Rayleigh and others. But the fact that the paper contains nothing essentially new does not diminish its value. Gibbs' phase rule, too, was new only in form, not in substance, yet it served as the crystallizing influence which caused an immense number of latent ideas to fall into line, and we may expect the II-theorem to play a similar role.

This inevitable development of technical physics into a unified branch of science, which will require the same fundamental place in the engineering curriculum that physical chemistry now holds in the chemical curriculum, can be facilitated if writers on the problems of hydro and aero dynamics, heat transmission and the like will be as introspective as possible, explicitly calling attention not only to their results, but to their methods of reasoning as well. For in every successful artifice of reasoning there must be some element which is universal, and capable of being generalized and made into a working tool.

In conclusion, the fact should be recorded that the writer's paper on the Laws of Lubrication is in part an application of the II-theorem, and that, therefore, the discussion of his paper is to be considered a continuation of the discussion of Dr. Buckingham's paper.

MELACH I. NUSIM. The author calls attention to the aid to be obtained in the application of the theory of dimensions in scrutinizing results of tests, and his general methods should be of value to engineers engaged in experimental work.

The conditions for similarity, discussed in the paper, have been noted and applied with great advantage by designers of centrifugal compressors and pumps. Two centrifugal compressors, if they are geometrically similar, have the same efficiency provided the following relation is maintained between the rated flow, Q , the peripheral speed of the impeller, S , and the impeller diameter, D :

$$\frac{Q_1}{S_1 D_1^3} = \frac{Q_2}{S_2 D_2} = \text{constant.}$$

The experimental data on one particular size of compressor can be utilized to predict with accuracy the performance of a number of sets provided they are made geometrically similar and rated according to the relation mentioned above. In terms of the mean effective pressure, P , the r.p.m., N , and the flow, Q (volume per unit of time), the relation is equivalent to

$$\frac{QN^2}{P^3} = \text{constant.}$$

A. R. DODGE said he had investigated the drop in pressure of superheated steam under similar conditions to those of Stanton and Pannell's experiments on air and water, using a 1-in. smooth drawn brass pipe, steam jacketed. The results obtained showed that the same formula for pressure drop would apply for steam, in addition to air, water and

oil. It ought, therefore, to apply for any fluid and simplify existing formulae.

He had also made a number of steam tests with commercial iron pipe, 2 to 8 in. in diameter, and found that the results were consistent, being only modified by the roughness of the pipe.

JOHN R. FREEMAN said that he possessed data of his own experiments with ordinary rough pipes, which might be of value in solving the problems presented. He said he had conducted a very extended range of experiments, in 1893, on pipes of all degrees of smoothness, from seamless brass pipe to exceedingly rough pipe.

L. W. WALLACE asked for further information in connection with investigations to determine certain facts in reference to locomotive sparks. It becomes necessary to know to what height sparks are ejected from locomotives under various operating conditions, and he asked whether experiments with a specially designed model locomotive would give data that would be comparable with the actual height the sparks would be thrown, the size of the sparks, etc.

THE AUTHOR. In reply to Mr. Wallace, it is conceivable that model experiments might be so devised as to furnish the desired information; the difficulties appear, at first sight, rather formidable. It is impossible to say off-hand, before examining the problem carefully, whether an attempt to solve it in this way would have any prospect of success. It would seem much simpler to study the actual emission of sparks from a locomotive by making runs at night and taking photographs—possibly kinematograph records—from two points on the train, one close to the locomotive and one much farther back.

In reply to Mr. Freeman, in trying to get an equation which could be made to represent the resistance of both smooth and rough pipes by varying only a single quantity—representing the roughness—the author had used Saph and Schoder's results exclusively, because in a preliminary study consistency was more important than accuracy. He had found, however, that the data were not sufficient for his purpose, and it would be a matter of great interest to him if he were privileged to examine Mr. Freeman's experimental results.

In reply to Mr. Dodge, it must be a satisfaction to all concerned with the subject of pipe resistance that the results of his wide experience with steam agrees so well with those obtained by Saph and Schoder for water, and by Stanton and Pannell for both water and air. We may safely conclude that the basis of physical ideas from which the dimensional treatment starts is sensibly correct and that no important element in the problem has been overlooked. The results obtained by dimensional reasoning are so instructive and the problem of pipe resistance so important that the confirmation which Mr. Dodge has given is a valuable contribution to the subject.

The example, brought forward by Mr. Nusim, of the practical utilization of the motion of dynamical similarity, is very interesting. The author's object in presenting his paper was to call attention to the method which, he is convinced, will in time come to be one of the engineer's handy tools, like the two laws of thermodynamics. But since he is aware that his opinion of the value of the method may be received somewhat sceptically by professional engineers, tes-

timony in its favor from one engaged in practical designing work is doubly welcome.

In reply to Mr. Hersey, mechanical engineering is an art, not a science; and the ability and imagination of the individual engineer will always be its most important element. But common sense tells the engineer to get as much outside help as he can in solving his problems, and one source of such help is physics. As Mr. Hersey points out, the aid to be got from physics does not consist merely in new determinations of physical constants or in experimental investigations of physical problems which are of special interest to engineers. It consists also in the systematic use of the scientific method of physics in analyzing problems, planning experiments, and coördinating known facts so as to bring to bear on any new problem all the available knowledge, of whatever sort and wherever obtained, which may seem to be pertinent. This is the technical physics which is destined not only to work in its laboratories on problems presented by engineers, but to be recognized as an inseparable companion of sound and progressive mechanical engineering.

length of a bearing, l , may be calculated from the equation

$$l_0 = \frac{L}{D} \cdot \frac{1}{p_0} \dots \dots \dots [3]$$

while the power dissipated in this bearing at a speed of n revolutions per unit time will be

$$P = \pi D n L f \dots \dots \dots [4]$$

Equations [3] and [4] are purely formal and their practical use demands a knowledge of some relation

$$f = \phi(p, n, D, l, \text{etc.}) \dots \dots \dots [5]$$

between the coefficient of friction and all the physical quantities governing the action of lubrication; together with some relation

$$p_0 = \psi(n, D, l, \text{etc.}) \dots \dots \dots [6]$$

between carrying power and the factors which it may depend upon.

Equations [5] and [6] symbolize the most important of the laws of lubrication needed in design; and they may be termed the *law of friction* and the *law of carrying power* respectively.

Definitions of friction and carrying power. Already the coefficient of friction has been defined as the ratio of frictional resistance to the load on the journal perpendicular to its axis; while carrying power has been defined as the greatest permissible bearing pressure.

A satisfactory definition of permissible bearing pressure demands a definite understanding as to the type of failure we wish to avoid. If we wish to avoid failure by seizing, we must investigate thermal expansion; if we wish to avoid failure by overheating the lubricant, we must investigate the temperature rise; if to avoid creating tension in the lubricant, we must investigate the pressure distribution; if to avoid simple abrasion, we must investigate the minimum film thickness. The last type of failure is the only type we shall undertake to discuss in this paper.

If e denotes the *radial clearance* or mean difference in radii between journal and bearing, while x denotes the *film thickness* or thickness of the film of lubricant at the point of nearest approach, the fraction $\frac{x}{e}$ may be called the *relative film thickness*. In this paper, we shall make it a matter of definition that all bearings are equally *safe* which are running with the same relative film thickness. Accordingly, carrying power may be defined as that bearing pressure which reduces the relative film thickness to some prescribed value $\left(\frac{x}{e}\right)_0$.

The determination of the laws of lubrication symbolized by equations [5] and [6] therefore simmers down to the investigation of the effect of various conditions on F and x .

Restrictions necessary to exclude unfamiliar phenomena. In order to narrow the problem down to as simple a one as possible we may impose the following restrictions:

- 1 The bearing must be in a steady state.
- 2 The lubricant must be homogeneous.
- 3 The bearing must be running below the critical speed at which eddy motion would be set up in the lubricant.
- 4 The effect, on the motion of the lubricant, of any other forces than hydrostatic pressure and shearing stress must be negligible.
- 5 The metal surfaces must always be separated by a film of lubricant which is thick enough to have the same mechanical properties it would have in bulk.

ON THE LAWS OF LUBRICATION OF JOURNAL BEARINGS

BY M. D. HERSEY, WASHINGTON, D. C.
Member of the Society

IN order to establish a rational basis for bearing design, it would be desirable to have empirical equations, or curves, showing accurately and completely how the friction loss and load-carrying power of bearings depend on all the physical conditions governing the action of lubrication, including, of course, the size, shape, and fit of the bearing, the speed, degree of lubrication, properties of the lubricant, and characteristics of the cooling system. The problem of mapping out the laws of lubrication in this general way, whether by piecing together existing data or by making new experiments, is such a complicated one that it is worth while to stop and consider whether any general principles are available which may serve to simplify it. A recognition of the above facts has led to the present paper.

Relation of laws of lubrication to design. After the requirements of strength and rigidity have been met, there may remain a question as to length and diameter which must be settled by reference to the laws of lubrication. Evidently too short a bearing is in danger of abrasion, while too long a bearing entails needless dissipation of power.

Let the coefficient of friction, f , be defined by the equation

$$f = \frac{F}{L} \dots \dots \dots [1]$$

in which F is the frictional resisting force and L the load on the bearing perpendicular to its axis. Let the bearing pressure, p , be defined by the equation

$$p = \frac{L}{D} \dots \dots \dots [2]$$

in which l is the length of the bearing and D the diameter of the journal. Let p_0 denote the carrying power or greatest permissible bearing pressure. Then the shortest permissible

Presented at the Spring Meeting of the Society, June 1915. Complete paper may be obtained without discussion, price 15 cents to members; 30 cents to non-members.

6 There must be no resultant couple acting on the bearing in the plane of its axis.

Qualitative discussion of action of lubrication. It is now shown qualitatively that, under the foregoing restrictions, F and x are completely determined by the following physical quantities:

- a* The viscosity, μ , of the lubricant.
- b* The revolutions per unit time, n .
- c* The load, L .
- d* The degree of lubrication; which, in the case of *stationary* lubrication (i.e., the limiting case when no lubricant enters or leaves the bearing) may be specified by Γ , the volume of lubricant in the bearing; and which in the case of forced lubrication may be specified by the quantity, Q , of the lubricant flowing through the bearing in unit time. Let S denote the relative supply $\frac{\Gamma}{Dlc}$.
- e* The absolute size of the bearing, which may be given by the diameter of the journal, D .
- f* The line of action of the load, defined by some length ratio r' such as the ratio or its distance from the middle point of the bearing, to the diameter.
- g* The shape of the bearing; specified by the relative clearance $\frac{c}{D}$, the relative length $\frac{l}{D}$ and such other length ratios r'' , r''' , etc., as may be needed to fix the shape of the oiling arrangements, deviation from circular section due to wear, departure from cylindrical form due to strain, and all other geometrical irregularities. Let r denote all the ratios r' , r'' , r''' , etc.

The conclusion that F and x depend only on μ , n , L , Γ , Q , D , $\frac{c}{D}$, $\frac{l}{D}$, r , may be symbolized by the equations

$$\Phi\left(\frac{F}{L}, \mu, n, L, \Gamma, Q, D, \frac{c}{D}, \frac{l}{D}, r\right) = 0 \quad \dots \dots [11]$$

and

$$\Psi\left(\frac{x}{D}, \mu, n, L, \Gamma, Q, D, \frac{c}{D}, \frac{l}{D}, r\right) = 0 \quad \dots \dots [12]$$

Derivation of the general form of the laws of lubrication by dimensional reasoning. An application of Buckingham's Π -theorem to equations [11] and [12] throws them respectively into the forms

$$f = \Phi\left(\frac{\mu n}{\rho}, \frac{D^3 n}{Q}, S, \frac{c}{D}, \frac{l}{D}, r\right) \quad \dots \dots [20]$$

and

$$p_o = \mu n \cdot \theta \left[\left(\frac{x}{c} \right)_o, \frac{D^3 n}{Q}, \frac{c}{D}, \frac{l}{D}, r \right] \quad \dots \dots [21]$$

f and p making their appearance in place of F and L by virtue of equations [1] and [2]. The functions Φ and θ are of course unknown, and remain to be determined by experiment.

Equations [20] and [21] correspond to equations [5] and [6] respectively, and contain the two laws of lubrication in their most general form. Now, any two bearings in which $\frac{Dn}{Q}$ has the same value, and in which S also has the same value, may be called *similarly lubricated*. Hence [20] and [21] are equivalent respectively to the following statements:

a In geometrically similar bearings which are similarly loaded and lubricated, the coefficient of friction depends only on the single variable $\frac{\mu n}{\rho}$.

b The carrying power of any bearing is directly proportional to the product of viscosity by revolutions per unit time, the constant of proportionality being the same for all geometrically similar bearings which are similarly loaded and

lubricated and which are equally safe, i.e., $\left(\frac{x}{c}\right)_o$ constant.

The writer made a series of experiments on journal friction and carrying power several years ago, the results of which are entirely consistent with the above conclusions.¹

Dynamically similar bearings. Any two geometrically similar bearings B and B' which are similarly loaded and lubricated, and which are running at the corresponding speeds, pressures, and viscosities defined by the equation

$$\frac{\mu n}{\rho} = \frac{\mu' n'}{\rho'} \quad \dots \dots [30]$$

have the same coefficient of friction and the same relative film thickness. Such bearings may be termed *dynamically similar*. The power dissipated in either of them may be calculated from a test made on the other, for

$$\frac{P}{P'} = \frac{D}{D'} \cdot \frac{n}{n'} \cdot \frac{L}{L'} \quad \dots \dots [31]$$

Moreover,

$$\frac{p_o}{p'_o} = \frac{\mu}{\mu'} \cdot \frac{n}{n'} \quad \dots \dots [32]$$

Thus if the carrying power of one bearing has been found experimentally, that of the other can be at once calculated.

A general method for determining thermal effects. The principal effect of temperature, and the only effect we need analyze here, is to decrease the viscosity of the lubricant as the bearing heats up. Consequently both friction and carrying power increase with speed less rapidly, under working conditions, than they would at constant temperature. The general dynamical equations [20] and [21] are true regardless of temperature, because they have been expressed in terms of the actual viscosity of the lubricant in the film at the moment in question; but it is desirable to go a step further. Equations like [20] and [21], which describe the behavior of a bearing when the viscosity is given, may be termed *characteristic equations* for that bearing. On the other hand, an equation describing the behavior of a bearing, not in terms of the instantaneous viscosity, but entirely in terms of known constants or controllable conditions like speed and load, may be termed a *working equation* for that bearing. Such an equation does not characterize the bearing in itself, but depends also on the nature of the lubricant and on the cooling system. A general method for determining the working equations for the friction and carrying power of any bearing is now outlined. The method consists in eliminating viscosity from the characteristic equations by utilizing information about the lubricant and the cooling system. Five relations are available, namely those connecting the quantities

$$\begin{array}{l} p_o \text{ and } \mu \\ \mu \text{ and } t \\ t \text{ and } H \\ H \text{ and } f \\ f \text{ and } \mu \end{array}$$

respectively.

The first of these is the characteristic equation for carrying power, equation [21].

Any empirical equation for the viscosity of an oil in terms

¹For a brief account of the experiments, see Jour. Wash. Acad. Sci., v. IV, p. 549, 1914.

of temperature must involve certain constants, which are different for different oils; if we denote all these by a , the second relation can be written

$$\mu = F_1(t, a) \dots\dots\dots [34]$$

in which the function F_1 is supposed to have been determined empirically.

Likewise the heat carried away in unit time at any temperature t may be expressed by some empirical equation

$$H = F_2(t, b) \dots\dots\dots [35]$$

in which b denotes all of the constants entering the function F_2 .

The fourth relation is obtained by equating J , the mechanical equivalent of the heat carried off in unit time, to the power dissipated according to equation [4].

The fifth relation is the characteristic equation [20] for the coefficient of friction.

Eliminating μ and H from the five relations leads to the three general equations

$$p_0 = F_1(t, a) \cdot n \cdot \theta \left[\left(\frac{x}{c} \right)_o, \frac{D^3 n}{Q}, R \right] \dots\dots\dots [37]$$

$$F_2(t, b) = \frac{\pi}{J} D^2 l n p \cdot \phi \left[\frac{F_1(t, a) \cdot n}{p}, \frac{D^3 n}{Q}, R \right] \dots\dots\dots [38]$$

$$f = \phi \left[\frac{F_1(t, a) \cdot n}{p}, \frac{D^3 n}{Q}, R \right] \dots\dots\dots [39]$$

in which R has been written for all the ratios $\frac{c}{D}$, $\frac{l}{D}$, and

r . These three relations may be regarded as a formal statement of the proposed method for determining thermal effects. The functions θ and ϕ are to be found by dynamical experiments; F_1 and F_2 by thermal experiments. After they have been determined, we can deduce a working equation for the carrying power by eliminating t from [37] and [38]. Likewise, by eliminating t from [38] and [39], we can deduce a working equation for the coefficient of friction. From [38] alone we get an equation for the permanent running temperature of the bearing.

If any of the empirical functions θ , ϕ , F_1 , or F_2 prove too complex to represent analytically, we can still accomplish the desired eliminations graphically.

The relations [37], [38], and [39] are perfectly general and not limited to any particular type of bearing or to any particular lubricant or cooling system.

Properties of the Ideal Bearing. The paper closes with a discussion of the *ideal bearing*—one which is perfectly circular in cross section, completely filled with lubricant, etc. While intended primarily as an illustration of the foregoing relations, and not for actual use in design, the equations of the ideal bearing doubtless afford an approximation to the laws of actual bearings. The characteristic equations for the coefficient of friction and carrying power of a *high speed bearing*, or ideal bearing with approximately concentric journal, are respectively

$$f = \phi \left(\frac{\mu n}{p}, \frac{c}{D} \right) = \pi^2 \frac{D \mu n}{c p} \dots\dots\dots [43]$$

and

$$p_0 = \theta \left[\left(\frac{x}{c} \right)_o, \frac{c}{D} \right] \cdot \mu n = A \mu n \dots\dots\dots [44]$$

in which the constant A is supposed to have been determined empirically.

The following are convenient approximations for the viscosity and cooling functions respectively:

$$\mu = F_1(t, a) = \frac{\mu_o(t_o - \tau)}{t - \tau} \dots\dots\dots [47]$$

and

$$H = F_2(t, b) = h(t - t_o) \dots\dots\dots [48]$$

Here μ_o is the viscosity at the room temperature t_o ; τ is the fictitious solidifying temperature; h the heat carried off in unit time per unit temperature elevation above room temperature.

If in [37], [38], [39], we now substitute the expressions for ϕ , θ , F_1 , F_2 , given respectively by [43], [44], [47] and [48], the following working equations result:

(a) For the permanent running temperature:

$$t = \frac{1}{2}(t_o + \tau) + \frac{1}{2}(t_o - \tau) \sqrt{1 + k n^2} \dots\dots\dots [59]$$

in which

$$k = \frac{4 \tau^3}{J} \cdot \frac{\tau_o}{h(t_o - \tau)} \cdot D^3 \cdot \left(\frac{l}{D} \right) \cdot \left(\frac{c}{D} \right) \dots\dots\dots [60]$$

The quantity k may be termed the *heating constant*; the greater it is, the hotter the bearing will run at any given speed. Evidently k may be determined from an observation of the permanent running temperature at any one speed, for by solving [59] for k we see that

$$k = \frac{\left(\frac{2 t - t_o - \tau}{t_o - \tau} \right)^2 - 1}{n^2} \dots\dots\dots [61]$$

(b) For the coefficient of friction:

$$f = \pi^2 \frac{D \mu_o n}{c p} \left[\frac{2}{1 + \sqrt{1 + k n^2}} \right] \dots\dots\dots [62]$$

(c) For the carrying power:

$$p_0 = A \mu_o n \left[\frac{2}{1 + \sqrt{1 + k n^2}} \right] \dots\dots\dots [63]$$

The above results apply only to the high speed bearing, for it is only when the journal is concentric that [43] is valid. The complete paper, however, contains a corresponding treatment of the ideal bearing with eccentric journal. Sommerfeld's work is made use of in this connection, and extended by an analysis of heating effects.

The paper contains illustrative examples, worked out numerically, and accompanied by diagrams.

Conclusion. It is apparent that the next step should be a minute examination of existing data, in the light of the foregoing principles. If it then appears that further experiments are needed, we may be guided as to the most economical way to plan them by reference to the general dynamical relations [20] and [21], and to the general thermal relations [37], [38], [39]. The dynamical relations serve to diminish the number of independent variables entering the characteristic equations. (Thus, the effect of varying all the factors μ , p , n , D , Q , can now be attained by changing two alone, such as μ and Q .) The thermal relations serve to diminish the number of combinations of conditions needed in determining working equations. It is a confusing task to map out the working equations of bearings under any great variety of circumstances by direct experiment, but a relatively simple matter to determine the dynamical characteristics of a bearing (ϕ and θ), and the thermal properties of a lubricant (F_1), and of a cooling system (F_2), by sepa-

rate sets of experiments. (Thus, in certain cases the function F_2 might be determined with a stationary dummy bearing, in which the heat is generated, regulated, and accurately measured electrically). It appears from this paper that it will be permissible to conduct such experiments separately; after which the results can readily enough be combined by the general thermal relations [37], [38], [39].

Finally, the conception of dynamically similar bearings may make it possible to evaluate some of the constants needed in design by the use of models—meaning of course by the model, any bearing whatever, found satisfactory in actual service, and which meets the condition of being dynamically similar to the bearing about to be designed.

DISCUSSION

H. F. MOORE. The paper appeals to the writer as an excellent example of the use of mathematical reasoning to facilitate and interpret experimental work. Coöperation between the mathematicians and experimenters is one of the most desirable technical achievements; many a carefully made set of experiments has gone for naught because of lack of analytical interpretation of results, or of proper theoretical lay-out of the tests, and many careful mathematical analyses have been valueless because the fundamental constants were wrongly assumed or not determined with sufficient accuracy.

The author's results on carrying power are qualitatively confirmed by the writer's experience. Experiments made by him in 1903 with a bearing of babbit metal on a steel journal showed that the carrying power of the bearing before the film of oil broke down increased with some function of the speed, and so far as the tests went the bearing power was found to vary approximately with the square root of the speed. Later tests made at the University of Wisconsin on very carefully ground hardened steel journals rotating in bronze bearings showed a carrying power two or three times as great as did the babbit metal bearing with unhardened journal. It might be expected that surface finish of journal and bearing would play a very important part in determining the breaking strength of the oil film.

W. H. HERSCHEL. The author's work is a notable step in bringing order out of the chaos of experiments on the friction of journals. If it can be demonstrated that viscosity is the only property of the lubricant which influences the coefficient of friction and the maximum permissible load, lubricating problems will be greatly simplified. Thanks to Sommerfeld, we no longer feel the necessity of considering "adhesion" which was introduced into equations by the earlier investigators, but there is a widespread belief that lubricants vary in regard to "oiliness," "lubricating value" or "body."

F. ZIE NIDEN contributed a written discussion in which after comparing the author's results with recent experiments carried out by Professor Guemmel in Germany and described in the Monatsblätter des Berliner Bezirks-Vereines Deutscher Ingenieure, May and June, 1914, he continued:

When gradually reducing (at constant pressure p) the speed of any bearing the value of the coefficient of friction in the neighborhood of zero, after reaching a minimum, abruptly increases to a high figure, because with very low speeds the liquid friction is giving way to semi-dry friction.

The laws as set forth in the paper do not then hold good. The point where this change occurs depends among others on the smoothness of the gliding surfaces. This consideration is by no means only of theoretical interest. Toothed wheels when running in oil will show lesser friction losses if designed so that the flanks of the teeth glide on each other with a speed exceeding the upper limit of semi-dry friction.

The all-important question whether equations (11) and (12) are qualitatively complete should be further investigated in connection with a long series of very important tests which Professor Schlesinger has brought forth in contention of the idea that it is not correct to assume that the only factor that matters in a lubricant (besides its price) is its viscosity.

The writer has come to the conclusion that two properties of the lubricant probably have something to do with the process of lubrication, both of which are not covered by the author's formulae. The first and less important one is the heat capacity of the oil itself, i.e., its specific heat. The second and very important one is the degree of amorphity. Lubrication depends entirely on the wedgelike action of the lubricant film. If the resistance of the lubricant against the mutual dislocation of its molecules is not absolutely the same regardless of the direction of the outer forces which tend to dislocate them, in other words, if the lubricant can no longer be regarded as a real amorphous liquid, then the application of Newton's law of viscosity will have to be modified.

Apart from optical reasons the change in the lubricating qualities of oils after some period of running would indicate that molecular forces are at work within lubricants which affect their action while not appreciably affecting their viscosity as measured by one of the ordinary viscometers.

Several very important conclusions can be drawn by the practical engineer from the results in this paper. One of the stipulations which is to be found in almost every specification for turbo-machinery is that the length of the bearings should at least equal three times the diameter. This rule of thumb probably is the outcome of practical experience gained with bearings of the comparatively low speed machinery exclusively used before the advent of the steam turbine. From the paper it follows the carrying power is different at different speeds.

The viscosity of the oil and the heat carrying capacity of the bearing are the essential standards which should be determined, but which are scarcely ever mentioned in any specification.

Of these two factors one depends on the buyer who supplies the lubricant for the machine he buys. Only the second factor, the heat carrying capacity, depends on the make. It is highly gratifying that the author shows a way to determine this quality of a bearing in a manner which will permit of standardization.

Until definite standards are developed, it would appear the safest way for a buyer to ask the maker for a guarantee of the temperature of the bearing, or rather of the maximum difference between room temperature and bearing temperature, provided such and such an oil is used.

In conclusion the writer considers the engineers of this country owe a very great debt of gratitude to the author for this valuable paper, and expresses the hope that his endeavors to map out the proper and most direct course for

the establishment of a rational basis for bearing design will be rewarded by a corresponding organization of the necessary experiments. If all individuals and laboratories, especially those of the Universities, who at present contemplate experimenting on the problem of lubrication of bearings could come together and assign among each other in a systematic and efficient manner the treatment of the various sub-problems as indicated by the present paper—then progress in the knowledge of bearing construction should be quick and radical.

THE AUTHOR. In discussing the value of coöperating with mathematicians, Professor Moore evidently refers to mathematics in the customary sense in which the term is stretched to include physics as well, but the writer would urge that we break this custom, and always distinguish physical reasoning from mathematical reasoning. The distinction may seem hair-splitting at times, and yet we all know what havoc has been wrought in the field of elasticity, for example, by elaborating mathematically relations physically unwarranted. Aside from the Π -theorem, which owes its value solely to its capacity for summing up physical facts, there is no mathematics at all in the important part of my paper, namely, the first twenty-five pages. What looks to be mathematics is merely symbolism—shorthand. The conclusion that a bearing can support a heavier load the faster it runs, follows from the physical facts about viscosity; and the general method for grinding out working equations is merely a condensed statement of a group of facts about heating and cooling, familiar enough to physicists, but which the cleverest mathematician alive might not have heard of.

Professor Moore's own formula, the square root law of carrying power, has been unwarrantably extended by others, and applied to circumstances physically different from those under which it was established. Nevertheless, the historical significance of his experiments of 1903 can hardly be over-estimated. They were the first experiments aiming toward a direct determination of carrying power.

While experimenting with bearings in 1909 at the Massachusetts Institute of Technology it occurred to the writer to see whether this square root law or any similar relation held under more nearly practical conditions; that is, with a whole bearing instead of a half bearing, and at higher speeds. It turned out that under these circumstances complete film rupture never took place, but that the load producing some specified electrical resistance other than zero did increase with speed.

As noted by Professor Moore it is to be expected that (except at high speeds), bearings with differently finished surfaces will behave differently; they cannot be considered geometrically similar unless they are either sensibly smooth or similarly rough—not equally rough, but twice as rough if twice as big.

Mr. Herschel alludes to the widespread belief that oils of the same viscosity may still differ in lubricating value. This belief is doubtless correct as regards bearings running at

low enough values of $\frac{u\eta}{p}$.

It would not be proper to comment in detail on Professor Guembel's work until Mr. zur Nedden's own discussion is printed in full. One fact may, however, be recorded for the interest of those who consult that reference in the meantime: If the curves on which Professor Guembel's final equa-

tions are based be fitted at three points instead of two, a more general type of equation results, which reduces to

Guembel's at low values of $\frac{u\eta}{p}$ and to Sommerfeld's at high.

It is true that the present paper is inadequate to cope with semi-dry friction, and it is likely that Professor Schlesinger's experiments, dealing as they do with the aggregate friction losses of the engine lathe, are largely concerned with semi-dry friction.

The specific heat of the oil has to be regarded as one of the b 's of equation [35] for heat carried off.

The writer does not believe there is, as yet, any need for considering the effect of incomplete amorphity.

Mr. zur Nedden's suggestions are exceedingly interesting, and must certainly be taken account of in the subsequent development of the subject. But, for the moment, we are so much at sea that it is well to follow the rule of navigation and keep to deep water, in doing which our six fundamental restrictions will serve as the channel buoys. Any exact charting out of the shoals has, to be sure, been postponed.

INFLUENCE OF DISK FRICTION ON TURBINE PUMP DESIGN

BY F. ZUR NEDDEN, NEW YORK, N. Y.

Member of the Society

INTRODUCTION

A DISK revolving in water acts as a brake. The losses due to the rotation of impellers in the water surrounding them amount to one-quarter to one-third of the total of the losses occurring in a high-lift turbine pump. It is astonishing that publications on the nature and magnitude of these losses are more scarce.^{1,2,3,4} There is very little reliable information on the question and that little is not arranged as designers would like to have it for us in commercial practice.

In the present paper, the results gained by Prof. A. H. Gibson⁴ are mainly employed in an effort:

- To find what means are at the disposal of the designer of turbine pumps for minimizing the losses due to disk friction.
- To furnish reliable data and diagrams from which to estimate the influence of disk friction on the efficiency of a turbine pump.
- To draw attention to the bearing which disk friction of the impellers has on the axial thrust of turbine pumps.

NOTATION

k_A and k_B = coefficients of friction between surfaces A and B respectively on one hand and the fluid surrounding the disk on the other hand.

Waste-water = fluid surrounding the disk.

f = Gibson's coefficient of disk friction.

v = abs. velocity of waste-water in ft.-sec. at the distance r from the axis.

⁴ Min. Proc. Inst. Civil Eng., London, vol. clixix, 1910, part 1.

Presented at the Spring Meeting of the Society, June, 1915. Complete paper may be obtained without discussion; 20 cents to members; 40 cents to non-members.

- v_p = absolute velocity in ft.-sec. of a point situated on the surface of the disk at a distance of φ from the axis.
- v_{DA} = abs. velocity in ft.-sec. of adjacent particle of waste-water.
- v_{pB} = abs. velocity in ft.-sec. of waste-water particles adjacent to casing at distance φ from axis.
- O_A = area in sq. ft. of that part of the impeller surface which is marked by fat contour in upper half of Fig. 1.
- O_B = area in sq. ft. of surface of casing as marked by fat contour in upper half of Fig. 1.
- P = dragging force in pounds of impeller, i.e., force exerted by impeller on waste-water which it causes to rotate.
- Q = retarding force, in pounds, of casing, resisting effects of P .
- ωT = angular velocity per sec. of waste-water.

- be made as small as possible; i.e., both the casing and the runner should be machined or polished as smoothly as possible.
- b* If a smoothly finished impeller revolves within a rough casing of a lateral width not exceeding about 5 per cent of the diameter of the impeller, the result is the same as if a rough impeller revolves within a smooth casing.
- c* The surface of the impeller and of the stationary parts of chamber C (Fig. 1) should be made as small as possible.
- d* The effect of an extended and complicated surface is equally bad whether this surface be the stationary wall of chamber C or the rotating surface of the impeller.
- The outward indication of the attainment of a minimum of loss through disk friction is the fact that the waste-water rotates just half as quickly as the impeller.

THE GYROSTATIC PRESSURE

The pressure due to the rotation of the waste-water is the source of important axial forces. At a distance of r ft. from

FIG. 1 KEY TO NOTATION

FIG. 2 GYROSTATIC PARABOLA

- ω = angular velocity per sec. of impeller.
- J_A = polar moment of inertia in ft⁴, of surface O_A with respect to axis of rotation.
- J_B = the same of surface O_B
- R_p and R_a = distance, in feet, of P 's or Q 's place of application respectively from axis of rotation.
- E_f = energy of disk friction in ft.-lb.
- h_g = gyrostatic head in ft.
- h_s = static head generated by impeller proper in ft.
- D_s = diameter of slip ring clearance in ft.
- D_i and R_i = diameter and radius respectively of impeller in ft.
- P_g = total gyrostatic force in lb., see equation [9].
- P_s = total axial force exerted by gyrostatic plus static pressure on the impeller in lb., see equation [10].
- N_T = number of revolutions of waste-water per min.
- N = number of revolutions of pump per min.

After pointing out the conditions when and where the disk friction may be expected to be the smallest possible, the author makes the following deductions:

- a* In order to reduce the loss through disk friction as much as possible, the coefficients of friction μ_{AS} and μ_{AB} should

the axis of rotation and an angular velocity of ωT per sec. this pressure in feet of fluid is

$$h_g = \frac{\omega^2 r^2}{2g} = \frac{vT^2}{2g}$$

where rT stands for the absolute tangential velocity of the waste-water in ft.-sec. and $g = 32.16$ ft.-sec.

When plotting these pressures as abscissae over the respective radii as ordinates, the parabola $A-B-C$, Fig. 2, is obtained. The pressure h_g is directed towards the circumference.

In turbine pumps the problem is to find the influence of the gyrostatic pressure upon annular surfaces, say, e.g., that part of the impeller which lies between slip ring a and its periphery (Fig. 3).

The gyrostatic force in pounds axially exerted by the rotating waste-water upon an annular surface is shown in this section to be

$$P_g = \frac{NT(D_i^4 - D_o^4)}{1000} \dots\dots\dots [9]$$

where

NT = rotative speed of waste-water in r.p.m.

D_o and D_i = the outer and the inner diameter, respectively, of the surface in ft.

and the total axial force in a pump which generates static pressure.

$$P_s = 49(D_2^2 - D_1^2) \left(h_s - \frac{4.25 N T^2 D_2^2}{100,000} \right) + P_g \dots\dots\dots [10]$$

where

D_2 and D_1 = outer and inner diameter, respectively, of annular face, in ft.

h_s = static head existing at circumference of impeller, in ft.

NT = rotative speed of waste-water in r.p.m.

P_g = gyrostatic force (see equation [9]).

The paper here surveys the experiments of Unwin and Gibson, considering the limitations of their formulae and also that of Biel for the theoretical loss through disk friction. It then develops the following expression:

$$h.p. f^1 = \frac{4\pi^{n+2} f}{550,30^{n+1} \cdot 12^{n+3}} N^{n+1} \frac{D_2^{n+3}}{n+3} \dots\dots\dots [12]$$

FIG. 3 GYROSTATIC FORCE ACTING UPON ANNULAR SURFACE

where

$h.p.f$ = loss due to friction on both faces of disk, without considering axial thickness, in h.p.

f = coefficient of friction, see Fig. 5, *a*, *b* and *c*.

n = exponent of friction, see Fig. 5, *a*, *b* and *c*.

N = r.p.m. of disk.

D^1 = largest diameter of disk.

This formula does not take into account the axial extension of the disk and so the author develops a corrective factor for use of designers, viz.:

$$h.p.f_n = h.p.f^1 \times \left[\frac{b}{D_2} \cdot (n+3) \right] \dots\dots\dots [14]$$

That is, in order to find the total loss due to friction both of the circumferential and the lateral faces of a disk, the value of $h.p.f^1$ obtained for the latter (equation [12]) should be multiplied by

$$1 + \frac{b}{D_2} (n+3) \dots\dots\dots [15]$$

where b is the total axial thickness of the disk, expressed in the same measure as D_2 .

In this way the designer can always, by a simple factor to be worked out mentally, consider separately and keep apart

the influence of the diameter and that of the axial extent of an impeller on the friction loss.

INFLUENCE OF ROUGHNESS OF DISK AND CASING

Figs. 5 *a*, *b* and *c* represent graphically the average variations of f and n in function of v_s as established by Gibson and Ryan for various degrees of roughness. Their results were compiled with those established by Professor Unwin's experiments and found to harmonize with them to a satisfactory degree. As set forth in Figs. 5 *a*, *b* and *c* the values of f and n furnish, within the range of speeds at which turbine pumps are run, figures for the losses (equations [12] and [14]) which always come within 5 per cent of the actual test results.

The second deduction at which the author arrived by a mathematical survey in this paper, viz.: "If a smoothly finished impeller revolves within a rough casing, the result

FIG. 4 DISK-FRICTION LOSS AS FUNCTION OF TEMPERATURE OF WASTE-WATER

is the same as if a rough impeller revolves within a smooth casing," is well corroborated by these curves.

The effect of metal polish and of varnish is almost exactly the same. This result should, however, not encourage manufacturers to resort to varnishing rather than machining the surfaces. Varnishing or japanning appears only at first sight to be the cheaper process. As a matter of fact, two coats of varnish require rather a long time to dry thoroughly. If the varnish or lacquer is not applied very carefully and dried well, or if the fluid to be pumped is not absolutely clean, the varnish will peel off. The surface then acts worse than even a rough casting. Polished surfaces, on the other hand, will often lose much of their original finish by the sediments of the water in the pump. It is, therefore, of no great use to expend much time and wages on a high, shining exterior finish of the impellers. It is sufficient to turn the faces off with a medium heavy cut, especially as the turning cuts are running concentric, i.e., in the direction of the flow of the waste-water.

Much saving can be effected if designers and shops cooperate in producing the smoothest possible castings to surround the waste-water chamber. This chamber should offer a minimum of surface and be free of any ribs, protrusions or re-

cesses which not only increase the surface and impede the rotation of the waste-water, but also frequently give rise to rough castings. If the designer gives the walls of the chamber a shape of utmost simplicity, the foundry will be able to produce faultless, smooth castings without extra cost.

Considerable though the differences due to various degrees of ordinary roughness in new pumps may at first seem, still it is only with typical high lift pumps that they appreciably affect the efficiency of the pump. This is especially true where the duty is small in comparison with the head per stage.

The paper here gives an example to illustrate this thesis.

INFLUENCE OF VISCOSITY, TEMPERATURE AND SPECIFIC GRAVITY OF FLUID ON DISK FRICTION

Inasmuch as oil, gasoline, hot water, etc., are today pumped by turbine pumps, the consideration of these influences gains

(65 deg. Fahr.) is eventually used, say, as a boiler feed pump and deals with water 200 deg. Fahr.

Of course, in a pump all the other causes inherent to the change of temperature are at work at the same time. For instance the loss of head owing to hydraulic friction in the fixed and rotative channels of the pump is likewise diminishing. On the other hand, the leakage loss must increase as the fluid becomes less viscous. The balance of all influences tends slightly to improve the efficiency of a boiler feed pump in actual service as compared with the figures obtained when testing it with cold water. The paper gives two examples illustrating the influence of heavy oil and tarry liquid on the disk friction in a turbine pump.

INFLUENCE OF DIAMETER AND SPEED

Formula [12] with $n = 1.8$ to 2, reveals at once the tremendous role the diameter plays. The influence of the rotary

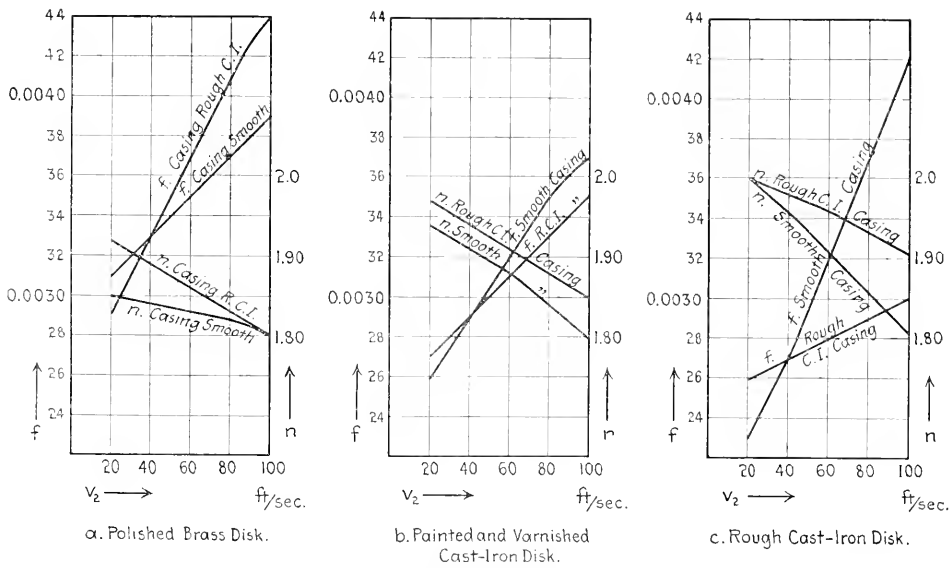

FIG. 5. DIAGRAMS OF DISK FRICTION ON POLISHED, PAINTED AND ROUGH SURFACES

in importance. The author has found it possible to answer the question of their respective magnitudes by a simple application of the theory of dimensions.

By considering the dimensions upon which the magnitude of the resistance depends, the expression

$$h.p.f = k' \sqrt{\frac{\mu \cdot n^4}{s}} v^2 a^2 \dots \dots \dots [23]$$

where μ = absolute coefficient of viscosity.

w = specific gravity.

s = lateral width of casing.

is deduced. It is easily seen that this is substantially identical with formula [12].

Fig. 4 represents the variation of $h.p.f$ with the temperature of the water. This curve may be utilized for estimating the improvement in power consumption which may be expected when a pump which has been tested with cold water

speed N is of relatively minor importance, though it is in proportion to about the third power of the number of revolutions.

As the duty of a turbine pump is in proportion to the speed, and the head in proportion to its square, the useful output is increased in proportion to the third power of the speed. It will be seen, therefore, that the loss through disk friction must form a constant percentage of the normal useful output, (water-h.p.), of a given pump irrespective of speed.

High heads per stage are more economically produced by applying high speed than by using a large diameter of the impeller. This economic tendency for the high-speed pump is fostered by a number of other incidental advantages, e.g., alternating current electric drive, direct steam turbine drive, small unit costs, small weight, reduction in tensile stress on casing, compactness, ease in transport and repairs, etc.

It might not be out of place to point out that the *angle between the impeller blades and the tangent at the periphery* has an important bearing on the loss through disk friction. If this angle is made 20 deg. the diameter must, from hydraulic reasons, be larger by 10 to 25 per cent. than if the angle were 45 deg. This implies for the flatter angle an increase in disk friction of at least 60 to more than 150 per cent in some cases. As the disk friction loss expressed in percentage of the useful work amounts seldom to less than 5

signer to abandon their preference for flat angles and to utilize the advantage that results from the consequent reduction in diameter and disk friction.

In order to enable designers and manufacturers to estimate the loss due to disk friction without resorting to formula [12] which is rather unwieldy for practical use, the author plotted the diagram Fig. 6, which should be self-explanatory. In basing the chart on the highest values found by Gibson and adding 15 per cent for friction of rim (supposed to be 3 per cent of D_2 thick) the author felt he should come nearest to conditions as they obtain in practice.

The author here gives some examples serving to illustrate the value and the mode of using this figure: the following example is a typical one:

Suppose 250 gal. per min. were to be pressed against a total head of 600 ft. and the speed of about 1800 r.p.m. had to be adhered to, say on account of 60 cycle a.e. current motor drive. What number of stages should be chosen?

As 200 ft. per stage is too much for that capacity, either a 4-stage, a 5-stage or a 6-stage pump must be employed. By using Fig. 6 the following table (Table 1) can be compiled without difficulty:

TABLE I
INFLUENCE OF NUMBER OF STAGES ON PERCENTAGE VALUES OF LOSS
THROUGH DISK FRICTION

Q = 250 gal. per min. N = 1800 r.p.m.	Head per stage in ft.	Water h. p. per stage	Loss through disk friction	
			In h. p. per stage	In percentage of water h. p.
4-stage pump...	150	9.5	1.62	17
5-stage pump...	120	7.6	0.98	12.9
6-stage pump...	100	6.3	0.66	10.5

If the 4-stage and the 6-stage pump were designed equally well, the 6-stage pump would have an inherent advantage, due solely to the number of stages, of about 6.5 per cent of the water-horse power, or about 4 per cent in efficiency. The first cost would be increased in proportion to the number of stages, and it would be a question of the cost of energy to the consumer whether the 4 per cent advantage in efficiency would outweigh the excess in price of the 6-stage pump over that of the 4-stage pump.

Looking at the question from the manufacturer's point of view, it might be possible, by abandoning certain niceties in design, for instance, the expensive guide vanes, to turn out a 6-stage pump actually as cheaply as the more elaborate 4-stage pump. If more than 4 per cent of efficiency was not sacrificed by that simplification the 6-stage pump would be as advantageous as the 4-stage pump—leaving out the question of number of spare parts, dimensions and weight.

One more point comes in for consideration: an impeller designed for 250 gal. only and required to pump against a 150-ft. head per stage would have to be large in diameter. As the duty is comparatively small, the passages at its circumference become rather narrow—too narrow perhaps for the cores to be properly fixed in the mould, or the passages to be well filed out in the shops. For this reason alone the head per stage is limited. The admissible minimum number in the present instance is probably 5-stage. The competition then stands between the 5-stage and the 6-stage pump. It is evident that it will be a difficult decision whether the

FIG. 6 LOSS THROUGH DISK FRICTION IN FUNCTION OF DIAMETER AND SPEED, BASED ON FORMULAE 12 AND 14

and often to more than 10 per cent in high lift pumps, it is evident that the mere changing of the vane angle from 20 to 45 deg. implies a profit of from 3 to 8 per cent and even more in the efficiency of such pumps. The reason why many designers like to choose flat angles of about 20 deg. is that the water then leaves the runner at a relatively high static pressure and low speed, i.e., that little or no attention need be paid to the balance of the kinetic energy. Diffusers or guide wheels may be dispensed with, and eddies due to an improperly simplified design of the casing cannot do much harm. Still, competition in regard to efficiency between various makes and the urgent demand of the salesman to reduce the motor power in order to minimize the cost of the unit to the consumer gradually force the manufacturer and de-

slight increase in efficiency due to the one stage more will warrant the extra cost of that stage. Leaving out the possible advantages in manufacturing costs which might result from a greater output, a skilful designer may be quite able to surpass the efficiency of a competitive 6-stage pump with a 5-stage pump of like or even lesser cost per stage, though the former has a natural advantage of 2.5 per cent less in disk friction.

At any rate the question will be of such nicety as to make it impossible for the buyer, judging merely from the number of stages, to have a sufficient insight into the merits of a pump. *Specifications, therefore, should not fix the number of stages, but leave this point to the discretion of the manufacturer.*

INFLUENCE OF LATERAL DISTANCE BETWEEN CASING AND DISK

Fig. 7 represents a diagrammatic compilation of the results which Gibson and Ryan obtained when varying the lateral distance, s , with those found by Wagner when rotating a disk in practically an unlimited basin ($s = \infty$) and by Dr. Becker when rotating a polished piston within a very narrow polished casing.

From the diagram it is clear that the loss due to disk friction has, in general, a rising tendency with increasing width, s , of the waste-water chamber.

Nothing can illustrate better than this diagram the necessity of using every caution in deriving conclusions from any mathematical survey of hydrodynamic problems.

The designer will draw two conclusions from Fig. 7. First, there is in general a tendency for the disk losses to rise when the width of the waste-water chamber is increased.

Second, concentric circular protrusions or ribs are not objectionable and might even be of advantage by breaking the secondary currents; while radial ribs must increase the disk losses because they favor the generation of induced currents and additional losses caused thereby.

INFLUENCE OF LATERAL DISTANCE AND ROUGHNESS UPON THE AXIAL THRUST

Professor Gibson, when investigating the effects of radial vanes attached to the impeller, measured the pressures generated by them. Incidentally he made a few readings from the gage attached for that purpose at the casing (which had an internal diameter of 13 in.) while rotating smooth disks. The author found that these accidental by-products of Gibson's tests are of the utmost importance for explaining and, therefore, mastering some components of the axial thrust which for a long time remained inexplicable to him and to many others.

In Fig. 8 the lower three curves (curves of h_s) are plotted from Gibson's results. They represent the pressure difference due to the rotation of the waste-water between the center and points at a radial distance of $6\frac{1}{2}$ in. from it.

From these readings it is possible to work out the rotary speeds of the waste-fluid, N'' , which, for the particular value of $r = 0.541$ ft. obtaining in Gibson's apparatus, is

$$N'' = 215 \sqrt{h_s}$$

By far the most important consequences follow from Fig. 8 when used to estimate what axial pressures will result if the roughness of disk or casing, or their distance from each other, differ on the two sides of the impeller.

Equation [10] furnishes the total axial force resulting from the coöperation of the static pressure h_s generated by

the impeller vanes at the circumference, and the gyrostatic pressure h_g . If the rotary speed of the waste-water N'' is different on the two sides of the same impeller an axial thrust results. This thrust is most striking with so-called balanced impellers, i.e., either double inlet runners, or runners having a slip ring on the back and borings leading from the inlet chamber through the eye into the chamber thus formed on the back (see Fig. 9). It shall be supposed that the static pressure generated by the impeller vanes is identical on both sides of the impeller. (This does not exactly hold true for single-inlet impellers for reasons which have no bearing upon the problem treated in this paper.)

FIG. 7 INFLUENCE OF LATERAL DISTANCE BETWEEN CASING AND POLISHED 12-IN. DIAMETER DISK

When making the above assumption h_g (see equation [10]) is eliminated when subtracting the total axial force on one side from that on the other, and the effect of the gyrostatic phenomenon can be treated independently of any other causes which might affect axial thrust.

After subtracting the two values which equation [10] assumes for two different rotary speeds of the waste-water bodies on both sides of the impeller, the following equation results:

$$P_{x-g} = P_g - P_g' - \frac{4.25 \cdot 49}{100000} (D'' - D')^2 (N''^2 - N'^2) \dots [25]$$

Introducing the values for P_g and P_g' which result from equation [9] this final expression is obtained for the differential axial force:

$$P_a = PL_{s-w} = \frac{NT^2 - NT'^2}{1000} [2.08 (D_2^2 - D_1^2) D_2^2 - (D_2^4 - D_1^4)] \dots \dots \dots [25a]$$

where

N' and N_T' = r.p.m. of waste-water bodies on two sides of impeller.

D_2 = outer diameter of impeller in ft.

D_1 = diameter of clearance of slip-rings in ft.

P_a = axial thrust resulting from difference between N and N_T' , in lb.

P_a' depends on the fourth power of the diameter. No appreciable inaccuracy is caused by disregarding the central part of the impeller.

Fig. 9 shows the direction of the resulting thrust P_a .

FIG. 8. ROTARY SPEED AND PRESSURE IN 13-IN. DIAMETER CASING PRODUCED BY 12-IN. DIAMETER DISK RUNNING AT 1200 R.P.M. IN FUNCTION WIDTH OF WASTE-WATER CHAMBER

The difference in pressure between axis and periphery is greatest where the waste-water rotates quickest (Fig. 9; right hand side—owing to small distance s). The static pressure h_s is the same on both sides. On the side where the waste-water rotates faster the gyrostatic pressure cuts out a greater parabolic area than at the other side. Therefore the total weight of pressure is smaller on the side where the waste-water rotates faster. Perhaps the following rule is easier to keep in mind: "The impeller is drawn to the side where the waste-water rotates fastest."

Two more examples, intentionally chosen to emphasize the necessity of the designer's attention to gyrostatic axial thrust, are here worked out in the paper. They show that an axial thrust of 440 lb. can be easily accounted for by the gyrostatic pressure differences forming in a 4-stage pump with

impellers 1 ft. in diameter and the lateral width of the waste-water chambers $\frac{1}{2}$ -in. on one and $\frac{1}{4}$ -in. on the other side of each impeller. Mention is made that further investigation of the details of the curves in Fig. 8 would be very desirable.

The gyrostatic axial forces, though important, do not constitute the only hidden cause of axial thrust. There are other variable components of the axial forces due, for instance, to the flow of the leakage water, or to the difference in pressure within the cells of the impeller, etc. Designers may never hope to obtain perfect balance under more than one particular condition or independent of wear and tear. They must always rely upon some strong hydraulic balancing mechanism or thrust bearing. The value of the above formula, therefore, lies principally in the possibility to foresee, by their aid, any danger that the axial thrust of the pump may act in the direction opposite or in addition to that for which the balancing device or thrust bearing is designed. It is known what strong axial forces can be exerted

FIG. 9. DIAGRAM INDICATING AXIAL THRUST DUE TO EFFECT OF ROTATION OF THE WASTE-WATER

by disks provided with radial ribs. In this connection the results which Professor Hesse derived from investigating hydraulic footsteps offer some valuable data to the designer, as does the paper of Gibson and Ryan. Not so well known, but no less remarkable is the effect of radial vanes in the fixed walls of the waste-water chamber. From the mathematical survey in Section II it is evident that their effect must about equal that of rotary vanes. The author knows of the experiences of a well-known pump manufacturer who had provided radial ribs in one, but not in the other waste-water chamber of a perfectly symmetrical double inlet impeller. The strong axial thrust which resulted was reduced to almost nil after the pockets between the ribs were covered by means of sheet iron, and incidentally the efficiency was considerably increased.

In case a designer should find it difficult for general constructive reasons, to shape both waste-water chambers exactly alike, he will, on the basis of the information contained in this paper, be able to counterbalance the effect of any differences in roughness and shape. It is scarcely necessary for the author to elaborate on this question which must be solved in a different way in each individual case.

DISCUSSION

C. GEORGE DE LAVAL. The author draws the conclusion that effect of roughness of surfaces on impellers and internal parts does not to an appreciable degree affect the efficiency of the pumps. In late researches by the National Physical Laboratory in England, it has been shown that the change from lamellar motion of liquid to eddying motion takes place suddenly at a definite value of the critical velocity and which is directly proportional to the kinematical viscosity of fluid. The conclusions by Lord Rayleigh indicate that, by the principle of dynamical similarity, the relation of bodies immersed in fluids moving relatively to them is a general law of resistance of bodies and depends on the velocity, density and kinematical viscosity of the fluid expressed by the formula

$$R = \zeta v^2 F \frac{(\mu d)}{s}$$

Where d = section or diameter of casing or pipe

R = resistance per unit area

s = specific gravity

F is a function of the one variable $\frac{\mu d}{s}$

ζ = density of water

v = mean velocity of water

μ = viscosity

The information given by the author is exceedingly interesting, particularly in the light thrown on fluids affected by viscosity, temperature and specific gravity. There is no doubt that little is known of this, not only on movement through pipes but also in chambers of centrifugal pumps. It is, no doubt, difficult to obtain a practical formula for use in dealing with very viscous liquids, nor can one estimate even approximately what can be expected in the way of power, speed and capacity.

The writer has found that results obtained are at considerable variance with what has been expected from mathematical conclusions based on existing laws of water. It would be most helpful if a commission were appointed to conduct a series of experiments to determine frictional resistances of oil and heavy viscous liquids in pipes, centrifugal pumps and reciprocating pumps and so finally establish a practical formula which could be relied upon. The oil industry is so great and important that more research information should be made available to the engineering profession than is now. Today we have not even a standard viscometer which is satisfactory; nor is a final method settled upon as to basis of figuring results and comparing with water.

The guaranteed performance of a centrifugal pump for oil is always based on clear water, the friction of oil in pipes and pump being assumed on this basis. The final results in pumping oil with a specific gravity of 0.87 show an increase of power of about 20 per cent and a reduction in head of about 20 per cent. The internal disk friction of impellers on account of viscosity of the oil causes the efficiency to drop 25 per cent. Theoretically the pumping head, whether oil or water, should be the same, but owing to the viscosity of the liquid there is considerable heat generated by the impellers in the pump chamber and the friction loss of the liquid increases, due to the viscosity in impeller passages, so that the head produced is about 20 per cent less than with water. It is, therefore, necessary that experiments are

resorted to as a considerable number of errors will creep in and give misleading results.

The author claims that he answers these important questions by theory without resorting to experiments. To the writer this appears a rather dangerous proceeding as to influence of viscosity, temperature and specific gravity of fluids on disk friction. Theories should be proved out by experiments. The work wasted in impeller friction, which is a wasted power due to skin friction, is the most serious loss and can be obviated by having the impeller revolve in atmospheric air, sealing the edges of outer circumference of impellers at each side of the rim and also at hub; this would go a long way towards increasing over-all efficiency and reduce the power. Any leakages at these points can be automatically taken care of, allowing this water to go back to its original source, the amount of which would be very small.

Impellers could be made also to operate in air pressure between impeller and casings. Both these methods would reduce the skin friction, gyrostatic and axial losses. Credit is due the author for bringing these subjects before us and his studies of the subjects give us considerable information on these important losses, about which there is very meager and incomplete information.

M. D. HERSEY. In order to be able to state that an equation is wrong because it is not dimensionally homogeneous, it is necessary that all the physical quantities which govern that fact must be included in the question of the equation; hence, while the noteworthy use which the author has made of this criterion, both in refuting Rossiter's equation and in developing his own results, is entirely legitimate, it is to be remembered that, in other cases likely to arise in hydraulics, if some physical quantity, such as gravity, has been suppressed, an equation not dimensionally homogeneous may still be correct.

THE AUTHOR. When the surface of an impeller is covered with sediments equalling the structure of fine sand, the friction loss may increase to three times its value with polished surfaces, or twice that prevailing when the disk consists of a smooth casting. However, such degree of roughness may safely be termed abnormal in turbine pumps, and the loss caused by an ordinary smooth impeller in most pumps is not so much greater than that caused by a polished disk that it pays to polish the impeller faces, especially as they soon lose their polish when running.

As to the influence of eddying and lamellar motion, it should be emphasized that unless the speeds of the pumped fluid are high enough to insure eddying motion throughout, the ordinary centrifugal pump is not fit to pump. The papers presented by Messrs. Buckingham and Hersey at this meeting deal more closely with the problems touched by Mr. de Laval.

The suggestion to entrust a special commission in this country with the experimental work on viscosity is an excellent one. The author intends to direct the attention of the U. S. Bureau of Standards to the advisability of establishing more firmly the standards and laws of viscosity. He would be glad indeed to have Mr. de Laval cooperate in this motion.

Mr. de Laval very aptly draws attention to the effect which the heat developed by impeller friction must have on viscosity. The author, however, has not committed the mis-

take imputed to him—that of resorting to theoretical rather than experimental solution of the question of the influence of viscosity, temperature, and specific gravity of the fluid. As a matter of fact, he resorted to dimensional reasoning in this instance only after very carefully investigating all available experimental evidence.

After the paper was written, the author applied formula [23] to some other tests carried out with syrup of known viscosity, gravity and temperature, and found that the calculation tallied very well indeed with experiment. The figures are at Mr. de Laval's disposal.

Unfortunately the figures quoted by Mr. de Laval are not conclusive, as he does not state the value of the coefficient of viscosity of the oil which he pumped. This, by the way, is a figure which pump-makers are almost never able to obtain from customers, but without which they are entirely unable to predict results.

The idea of trying to rotate the impeller in air instead of water is not new. The author has himself given it a considerable amount of thought which he condensed in his application for German patent, No. N. 11099. There also are some French and American patents covering similar efforts. The practical difficulties which stand in the way of this idea, however, are very great indeed. How, for instance, is it to be avoided that the impeller should suck air from the lateral chambers?

At present those high lift impeller designs which tend to diminish the diameter of the impeller, i.e., to diminish the impeller coefficient, deserve more attention. The reduction in disk friction loss is about five times the percentic reduction of this coefficient.

The point raised by Mr. Hersey will be treated in my discussion of this gentleman's paper.

A BASIS FOR RATIONAL DESIGN OF HEAT TRANSFER APPARATUS

E. E. WILSON, NEW YORK
Non-Member¹

AN examination of the literature on the subject of heat transfer shows such a wide variation in the coefficients established that it is difficult to make a choice for use in practice. The fact that the results of careful experimenters do not agree leads to the conclusion that some variable or variables have been neglected, and the fact that the rate of heat transfer in feed water heaters is consistently greater than that in the similar apparatus, the condenser, indicates that one such neglected variable is the temperature of the circulating water. It is the purpose of this paper to apply a correction for the water temperature to the results of reliable experiments.

By correcting for all variables, the rate of heat transfer which is generally expressed as some exponential function of the circulating water velocity, may be expressed in a different form as a straight line function. With this relation it is possible to evaluate the thickness of a water film capable of offering the same resistance to heat transfer as is

encountered on the water side of a condenser or feed water heater. From the known internal conductivity of such a film it is possible to develop an expression for the area of heating surface required to transmit a given quantity of heat under all conditions of circulating water velocity and temperature, mean temperature difference, and tube diameters. With the use of suitable design factors this expression for area may form the basis of rational design, while a consideration of the manner in which the variables appear may be of assistance to the operator.

The possibility of solution along the lines indicated was brought to the author's attention by Dr. C. E. Lucke of Columbia University.

In condensers and feed water heaters the resistances to heat flow for clean tubes are:

- That due to the thickness of the tube walls.
- That due to the film of water on the steam side next the tubes.
- That due to air in the exhaust steam.
- That due to the water film on the water side.

FIG. 1 VARIATION OF LOSS OF HEAD IN PIPES AS REPORTED BY OSBORNE REYNOLDS, PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY OF LONDON, 1883

Under ordinary conditions of operation (d) will be the controlling resistance and any increase in heat transfer should come through reduction of the film thickness on the water side. This is evident when the general law of heat transfer is considered. Taking the analogy of the electric or magnetic circuit we may write,

$$U = t_m \div R$$

in which

U = B.t.u. transmitted per hour per sq. ft.

t_m = mean temperature difference between the hot and cold fluids

R = resistance to transfer

Putting in the individual resistances enumerated above this becomes

$$U = \frac{t_m}{R_w + R_s + R_c + R_t}$$

in which

R_w = resistance of the water film on the water side

R_s = resistance of the air film on the steam side

R_c = resistance of the water film on the steam side

R_t = resistance of the tube walls.

If z be the resistance per unit of film thickness and l , the thickness of the film the expression becomes

$$U = \frac{t_m}{z_w l_w + z_s l_s + z_c l_c + z_t l_t}$$

¹ Lieutenant, U. S. N.

in which we have the heat transfer in terms of the film thicknesses involved.

Considering now the controlling resistance, that on the circulating water side, we find that this decreases as the water velocity increases. Just how it decreases has been the subject of much investigation and the results have been summed up by G. A. Orrok¹ in his paper.

In his Scientific Papers, Osborne Reynolds pointed out that if a fluid traversed a tube without turbulence, the resistance to the transfer of heat would be entirely independent of the velocity; while, if the flow were turbulent, it would vary inversely as the velocity. In a later paper he showed that the transition from non-turbulent to turbulent flow was a discontinuous phenomenon: on a certain critical velocity being exceeded, turbulence abruptly sets in. Hence, when heat is being transferred from a hot tube to a fluid flowing in it, the law of heat transference changes abruptly once the critical velocity is reached.

The critical velocity according to Reynolds is given by the relation

$$V_{\text{critical}} = \frac{1}{B} \cdot \frac{P}{d}$$

where

P = Poiseuille's value for the ratio of viscosity to density

d = internal diameter of the tube.

B = a constant

The value of P in centigrade units is given as

$$\frac{1}{1 + 0.0336T + 0.000221T^2}$$

in which T is the absolute temperature centigrade.

If now the value of P at some one temperature, such as 60 deg., be settled upon as the standard, the ratio of P at any other temperature to that at the standard temperature may be computed as a specific viscosity.

The view that the rate of heat transfer should vary inversely with the viscosity was arrived at through consideration of the similarity between the accepted law for heat transfer and that for the loss of head in pipes. Reynolds found that up to the critical velocity the loss of head varied directly with the velocity as shown in the lower branches of two of his results in Fig. 1. The coordinates here are the logarithms of the loss of head and velocity, and the slope of the lower branches is 45 deg. At the critical points C' and C'' the flow becomes turbulent and the slope of the curve changes to about 1.72. Reynolds shows further that the temperature of the water and diameter of the tube have little or no effect upon the slope of the curves but that these may be shifted so as to be exactly coincident. The component of this shift in the direction of the velocity is 0.297 on the figure and this corresponds very closely to $\log P/d$ in the expression for critical velocity above.

With these facts in mind the results for heat transfer were investigated and those reported by Orrok were selected as being the most complete and accurate. The mean temperature of the circulating water was computed from his factors of correction for viscosity and the data grouped in accord with certain average temperatures. The results are plotted in Fig. 2 from which it is seen that there is a distinct shift from the mean of the points for the lowest temperature to those of the highest temperature. Of course these results are too few and, not having been obtained with this purpose in mind,

are too inaccurate for quantitative results, but they show well enough the qualitative effect.

The points defining the five lines of more or less equal temperature form a wide band. If, however, we apply a correction similar to that for the critical velocity so as to reduce the results to some common temperature, say 60 deg., the width of this band is cut in half. For instance, if the mean water temperature in one case were 40 deg. and the velocity 5 ft. per sec., the resistance to heat transfer would be the same as if the temperature were 60 deg. and the velocity

$$\frac{5 \times P_{60}}{P_{40}} = 3.62 \text{ ft.-sec.}$$

This correction has been applied and the results as reduced from a 1-in. to a 5/8-in. pipe are plotted in Fig. 5 along with the uncorrected data. The reduction in the dispersion

FIG. 2 RATE OF HEAT TRANSFER VERSUS CIRCULATING WATER VELOCITY. RESULTS OF TESTS BY ORROK, TRANS. AM. SOC. M. E., 1910

is quite marked and the agreement, in view of the difficulties in eliminating air from the steam in a test of this sort, becomes now quite good. There is a tendency toward curvature in the plots but this is not well enough defined to permit of reevaluation owing to the scarcity of points at the low velocities.

By further reasoning it is found that there is a linear relation between the resistance on the water side and one variable, the velocity, after the other variables have been taken care of in reducing the velocity. The resistance of the tube walls for clean tubes is well known and that on the steam side has been determined for the one case, that of steam at 212 deg. The curves resulting from plotting experimental data will lie above that due to the sum of the resistance as calculated, because in practice steam is never quite air free and the resistance on the steam side is increased by that due to the air.

This constitutes the reduction for viscosity, but when the results of different experimenters are considered it is found that different sized tubes have been used.

But

$$\frac{500}{R_{1/2}} = \frac{\text{Inner diameter}}{\text{Outer diameter}}$$

¹ Trans. Am. Soc. M. E., Vol. 32, p. 1139.

$$(Rw)_1 = (Rw)_{\frac{1}{2}} \times \frac{1.00}{0.902} \times \frac{0.529}{0.625} \times \frac{0.529}{0.902} = 0.55 (Rw)^{\frac{1}{2}}$$

gives a reduction factor for relating the two sizes of tubes on the basis of the resistance of the water.

As an example of the method of applying the corrections for working up the results, take the first run in Orrok's results. Here $V_w = 11.2$ ft. per sec.; $t_s = 126.3$ deg.; $t_m = 73.2$ deg.; $U = 1000$. Now $t_s - t_m = 54.1$ deg. From the table of correction factors, Table 1, $C = 1.10$. Then

$$V_{w0} = \frac{11.2}{1.10} = 9.3$$

$$U_{final} = V_{w0} \times \frac{0.902}{0.529} = 9.3 \times \frac{0.902}{0.529} = 15.9$$

of which the reciprocal is 0.063. This can be raised to the 0.82 power by laying off a pair of scales, one of which will show V when the other gives $V_{w0}^{0.82}$. By this method the result is 0.102.

$$R = 1000 \times \frac{1}{V} = \frac{10,000}{1000}$$

or in this case, 1. The coordinates of a point on the final curve are then 1 and 0.102.

It is not absolutely necessary, as has been done so far, to deal with these resistances in terms of an arbitrary unit, since the resistance may be expressed in terms of the thickness of equivalent water films, by a simple transformation. When this is done we have the thickness of the films on each side and that of the tube wall expressed as a water film thickness, and we have the film thickness on the water side in terms of one variable which has been reduced in such a manner that all other variables are accounted for. In other words, we have a linear relation between the physical object offering the resistance and the factors upon which it depends for its magnitude.

It now remains to express the results algebraically and this may be readily done. Since the curves are of the form $y = mx + b$ we have, measuring the values of m and b on the line for "resistance as measured" in Fig. 3,

$$l = 0.0143 \left(\frac{1}{V_{w0}} \right)^{0.82} + 0.00313$$

Now the reduced velocity V_{w0} was corrected for both viscosity and the diameter of the standard 5/8-in. tube, 0.529 in. If we let d be the inside diameter of the tube under test and P_t be the viscosity \div density for the mean water temperature as before and P_{w0} the same ratio for the standard water temperature we can write

$$l = 0.0143 \left(\frac{P_w \times 0.529}{V \times P_{w0} \times d} \right)^{0.82} + 0.00313$$

Calling the ratio of the viscosities C_w , water correction, and reducing we find

$$l = 0.0085 \left(\frac{C_w}{V \times d} \right)^{0.82} + 0.00313$$

If now C_w can be expressed in terms of the temperature we have an expression involving the film thickness and all the variables concerned. In Fig. 4 the values of C have been plotted against absolute temperature in deg. Fahr. on logarithmic paper, and it is seen that while the curve is not exactly straight it can be divided into two sections which are

practically so. The lower section has a range from 32 to 140 deg. Fahr., which embraces the temperatures met in condenser practice and greatly exceeds the limits in this practice. Expressing the lower section algebraically we have

$$C_w = \left(\frac{520}{T_w} \right)^{0.57}$$

From which, and the expression for l above

$$l = \frac{34.0 \times 10^{12}}{T_w^{0.58} \times (V \times d)^{0.82}} + 0.00313$$

For water temperatures outside this range, such as those met in feed water heaters, the upper section may be used and a similar expression obtained.

This expression is a rational one as far as film thicknesses are concerned but is still not in a practical form. To reduce

FIG. 3 RESISTANCE TO HEAT FLOW IN TERMS OF "FULLY REDUCED," VELOCITY OF CIRCULATING WATER. ENGINEERING, JAN. 23, 1914

it to such form, the general law of heat transfer is utilized. According to this law

$$Q = AU t_m$$

in which Q is the heat transferred per hour, A , the area of the heating surface, and t_m the mean temperature difference as before.

Remembering that we can now write

$$U = \frac{1}{2l}, \quad A = \frac{2l}{t_m}$$

from which

$$A = \frac{Q}{3.48 \times t_m \left(\frac{34 \times 10^{12}}{T_w^{0.58} (V \times d)^{0.82}} + 0.00313 \right)}$$

Upon further reduction this becomes

$$A = \frac{Q}{t_m \left(\frac{976 \times 10^{10}}{T_w^{0.58} (V \times d)^{0.82}} + 0.0009 \right)}$$

This is a rational expression for the area of the heating surface required in a condenser in which all the surface is active and in which steam is substantially air free, as it exists when an effective dry vacuum pump is in use.

The above rational expression for the area of condensers, the determination of the actual thickness of the dead fluid film and its variation with the flow conditions, suggests a method of dealing with all heat transfer apparatus, dependent upon the same principles.

Conclusions. In condensers and feed water heaters, using

practically air free steam, the controlling resistance to heat transfer is on the water side. This resistance is a function of the water velocity, its mean temperature and the diameter of the tubes, and it varies inversely as these three variables, according to a straight line law. Large quantities of air collecting in pockets on the water side greatly increase the resistance to heat flow while the quantity of solid matter contained in the circulating water may increase the apparent resistance by increasing the apparent velocity as determined by the weight of water passing. The viscosity of the circulating water has an important influence on the resistance, since the warmer the water the less resistance it offers. The resistance due to oily circulating water may be greatly different from that of fresh water. Finally by analysis of reliable test data it is possible to get an expression for the area of heating surface required to transmit a given quantity of heat, in terms of prime variables, from which it is seen that the area varies directly as the quantity of heat to be transferred per hour per square foot, and inversely as the circulating water velocity and its mean temperature, as well as the tube diameter. Such an expression, based on good experimental results, should replace empiric coefficients in design and assist materially in operation.

DISCUSSION

ROBERT C. H. HECK stated in a written communication that the argument is developed so much by the experimental method that the title "rational" seemed to him to be fully deserved. The argument from analogy between the law for heat transfer and that for the law of head in pipes appeared to him to be rather far-fetched, the functions used not being really enough alike in their manner of variation to warrant such an assumption. Besides, the assumption that general velocity states are proportional to critical states is not yet proved. He could not accept the assumption that because, with the same water temperature, the critical velocity in a 1-in. tube is only one-half as great as in a half-inch tube, therefore the unit surface of the larger tube is twice as effective as the unit of the smaller tube. The idea of complete inverse proportionality to temperature appeared to be too simple and not yet proved experimentally. He believed that the difference of slant in the final line of Fig. 7 and 8 was due more to excessive influence of tube diameters than to the causes named by the author.

LEO LOEB objected to the fundamental conclusion of the writer that the control resistance to heat transfer from the condensing vapor to liquid warming rests on the liquid side and that the numerical value depends on the three factors of water velocity, mean temperature and tube temperature. Recently types of apparatus have been produced in which the agitation of the liquid is carried to the highest practicable point consistent with reasonable frictional resistance and it appears that in the near future the largest part of such apparatus will embody construction principles which will make it altogether impossible to base results on either velocity or temperature.

Variation in results reported by several investigators may be due to lack of standard methods of tests and of uniformity in the presentation of data as well as, in some instances, to

an improper conception of the meaning and application of the term "temperature difference." Thus accidental errors may be due to difference in temperature across the cross section of a pipe where the outlet temperature is measured. Several instances have shown that water is discharged from different portions of the heating surface in streams of varying temperature and that these streams did not diffuse readily.

He objected to the assumption generally made that the law of heat transfer is analogous to that of an electric or magnetic circuit which it can be only when there is under consideration a single thermal resistance, a case which never occurs in practice.

He further discussed his own tests conducted at the Naval Engineering Experiment Station upon single tubes and normal heaters (Published in the Journal of the American Society of Naval Engineers, May, 1915; compare abstract in The A.S.M.E. Journal, August, 1915), and their bearing on the theory presented by Lieutenant Wilson.

FIG. 4 CURVES OF CORRECTING FACTORS FOR VARIATION IN VISCOSITY DUE TO TEMPERATURE OF CONDENSER CIRCULATING WATER

H. WADE HIBBARD made a plea that whenever mathematical papers are presented before the Society the authors use footnotes showing how they have evolved their equations, in the most elementary fashion. He had observed that mathematical papers presented before the Society in years past had received scant discussion, due in part to the jumps in the mathematics in the papers.

The author mentions that "The controlling resistance to heat transfer is on the water side," showing how much emphasis he places upon the word "controlling." In condenser practice we have rain plates so that the moisture will be removed from the tubes as quickly as possible and the steam which follows will strike against tubes that are not encased in wet film.

EDGAR BUCKINGHAM contributed a written discussion of the physics of the subject of heat transmission, in which he showed that the heat transmitted to the liquid from unit length of the tube in unit time could be expressed by an equation of the form

$$Q = DV\rho C' \Delta\Phi \left\{ \frac{DV\rho}{\mu} \cdot \frac{V^2 a}{C'} \cdot \frac{\mu C'}{\lambda} \cdot a \Delta \right\}$$

where

D = internal diameter of tube

V = speed of fluid

ρ = density of fluid

μ = viscosity of fluid

C' = specific heat of fluid

Δ = temperature difference

λ = conductivity at mean temperature of section

α = temperature coefficient of conductivity between this and temperature of inner surface of tube

Φ = an unknown function which remains to be determined.

This equation shows that a complete investigation of the problem of heat transmission, even for a single liquid in so simple apparatus as a condenser tube, is rather complex. To determine the value of Φ it is necessary to find the effect on Q of varying four arguments of Φ separately. In view of our almost complete ignorance about the thermal conductivity of water, to say nothing of other liquids, it is not surprising that we do not yet know all there is to know about heat transmission; and any attempt to proceed rationally, as Lieutenant Wilson has done, by taking into account and allowing for the various physical quantities that may be involved in the process of heat transmission is very much to be welcomed.

ARTHUR M. GREENE, JR. I would like to ask the author how he proposes to get the mean temperature so as to use the results of his work, and also how he got the mean temperature which he did use.

As Mr. Braun points out, if he uses the arithmetic mean or the logarithmic mean, he gets two results; and if the viscosity is affected by the temperature he has got to consider that fact in finding the coefficient of heat transfer. It seems that both of those methods in getting t_m are incorrect and you have really to find t_m by the method that Orrok uses in his work on the condenser.

I would also like to say that Mr. Leo Loeb's paper, which recently appeared in the Transactions of the Institute of Naval Engineers, clearly points out the fact that this heat transfer coefficient varies with the temperature. The method he uses is rather unique, and proved clearly, I think, that we must use some exponent form for the computation of T_m . If we do this it seems to me better than to use an expression involving viscosity.

C. F. BRAUN. This paper is particularly interesting to the writer because it treats in a most thorough manner a factor in calorifier design, which is given only slight attention in my condenser paper.

Unquestionably the resistance to heat flow on the fluid side of a tube increases rapidly with increase in viscosity and is a most important factor in the design of calorifiers for such viscous fluids as oils, syrups, etc., having viscosities ranging up to 50 times that of water. As the oil industry particularly is an important one in this country and the demand for oil heaters and exchangers large, the development of rational formulae relating to heat transfer and viscosity would be very valuable, and can the author extend his researches to these fields he will render a service to the profession.

The viscosity of water varies so slightly within the ranges of temperatures encountered in heater and condenser practice that its effect, I feel, is almost negligible compared with that of other variables indeterminate and difficult to control. I am a great believer in figuring, but we must eliminate unimportant complications, or we avoid and do not use our theory.

One of the greatest variables in determining the unit coefficient of heat transfer for comparison of different experimental results is the method of computing the mean temperature difference. Without discussing the merits of the various formulae, it is sufficient to call attention to the fact that the arithmetic mean, logarithmic mean and others produce widely varying results, particularly when the ratio between the least temperature difference and the greatest temperature difference is small.

Again the amount of air present is a variable which cannot be controlled or its effect determined, and will invariably produce variations far beyond the limits of viscosity effects.

The density or mass flow of the steam, while apparently having no important effect upon heat transfer, may very probably have as much if not more effect than the viscosity of the water.

I also thoroughly believe that heat transfer varies inversely with tube size and to a far greater degree than with water viscosity. Experimental data on this point would be valuable.

Unaccountable discrepancies in condenser test results are very frequently the result of assuming a uniform temperature in the steam space, instead of obtaining an average which may fall considerably below that at the inlet, due to frictional pressure drop through the tube of space, and to the presence of air.

THE AUTHOR. Professor Heck criticises the reference to the similarity between the laws of resistance to the flow of water and heat on the grounds of dissimilarity of exponents. The mere numerical value of these exponents is of little importance for the purpose in hand. It was the similarity in form of the accepted law that led to the study, and although this study showed the exponential law to be incorrect for heat transfer, nevertheless the remarkable facility with which all data are reconciled by the viscosity correction is justification enough for the method.

Professor Heck also objects to the use of the word "rational." My understanding of the meaning of this word as applied to an equation is that an expression is rational when it so involves the different variables that the truth may be checked up by the fundamental dimensional equations. Doctor Buckingham's very interesting paper treats of that same subject. Taking the expression for film thickness in the paper we have,

$$L = \frac{a}{V} \div b$$

where L is the thickness, V , the reduced water velocity, a , the slope of the line, and b , the intercept on the vertical axis, Figs. 7 and 8. In this expression b has the dimension L ; V is of course L/T ; a is L/V or L^2/T , and we then have

$$L = \frac{L^2 T}{TL} \div L = L$$

which is a rational expression. Referring to the expression for the area we have

$\frac{A}{t_m} = Q \frac{L}{t_m}$ in which L is taken as the expression above.

by definition $Q \ t_m = U$, and $P = L \ U$ from which

$$A = \frac{U L^2}{U} = L^2$$

which expression is again rational.

As for the influence of the tube diameter to which Professor Heck takes objection, there seems no reason for endeavoring to find a more complicated function. The resistance to heat flow and water flow are both a function of the water agitation. In the flow of water the diameter is shown by Reynolds to have a certain influence on the critical point, that is the point at which the flow becomes turbulent, and this feature in turn affects the resistance to flow. It seems not unreasonable to expect the diameter to have the same sort of influence on heat transfer, which is dependent upon the agitation in the same manner. In comparing a half inch and a one inch tube as to the effectiveness of the unit surface it must be borne in mind that for the same linear velocity the quantity of water passed increases as the square of the diameter. If now the flow is turbulent, there can be a larger number of impacts on the unit surface of the larger tube than of the smaller, and this accounts for the greater effectiveness.

Professor Greene has asked the method of obtaining the mean water temperature. This is shown in the tables where I have subtracted the mean temperature difference t_m from the temperature of the steam t_s , thus getting t_w , the mean water temperature. Both Mr. Braun and Professor Greene have discussed the mean temperature difference. I am aware of the difference of opinion as to the proper way of getting this. Mr. Orrok in his calculations used the arithmetic mean for the reason that the difference in results by different methods when the temperature rise is small is not worth considering.

Mr. Loeb states that no useful purpose can be served by considering the high circulating water temperature in design where space and weight are limited. On the other hand this seems to me to be the very place careful design is needed. As an example take the condenser design of a battle cruiser developing say 120,000 horse power, on a small displacement. Her condensers will be beyond the limits of present practice so that no comparison may be had with other vessels, yet, on the other hand, space will be so confined as to preclude guess work. Surely accurate design is needed here.

Mr. Loeb calls attention to the fact that the variation in results reported by several investigators may be due to experimental errors, rather than the neglect of the variables mentioned. I appreciate fully the difficulties of work in this field and drew Fig. 9 as an example. My point is that the wide variations in the results of so excellent an investigator as Mr. Orrok are not explained by experimental errors but by neglected variables instead. When in Fig. 5 of the paper I corrected his results for temperature, they became recon-

ciled to a point where further difference might be assigned to experimental inaccuracies.

The objection by Mr. Loeb that the analogy of the law of the electric circuit can apply only when we have a single resistance is not sustained. We are fully justified in writing such a law if we remember that the resistance in this case is a variable. Mr. Loeb practically uses the same analogy in his paper, but instead of separating the resistance into its component parts he assumes that he is keeping this constant when he maintains the water velocity constant and determines an exponent for the mean temperature difference. In the general expression,

$$U = \frac{t_m}{R_w \div R_s \div R_a \div R_t}$$

R_w is not dependent upon the velocity alone, but also on the mean water temperature, and his failure to consider the temperature is probably responsible for the value of his exponent for t_m , and its difference from unity. Any exponential law for heat transfer involving either U or t_m , however convenient it may be for the design of a limited class of apparatus, cannot be considered a valid general law. As Mr. Loeb says any one can run a few tests and use them as a basis for design for similar apparatus involving the same conditions. Surely, however, we are not entitled to use these few results in writing a general law for the whole subject. Mr. Loeb, in his paper, has developed in a novel manner an excellent method of designing certain types of apparatus, but these same data could not be extended to other types.

The objection that new types of apparatus have been evolved in which agitation is carried to the limit so that viscosity need not be considered, is hardly valid. We have two distinct methods of reducing the resistance, mechanical agitation and increased water temperatures. In certain types of apparatus the first method is carried to the limit, but this does not remove the influence of temperature on the thickness of the water film.

In regard to the value of the exponent of U in the paper, there is no connection between this exponent and that used for t_m by Mr. Loeb in his article. The value 0.82 was settled on by the author of Fig. 7 in *Engineering* apparently by trial. I have since plotted the results of Mr. Orrok's work against U with the index unity and find excellent accord. Further experimental work must determine the real value of the exponent.

In conclusion I want to point out that successful design of heat apparatus has been done empirically and will continue to be so done. In all design, however, we must appreciate two great classes, (1) Functional Design and (2) the Design of the Mechanism. Mr. Braun in his paper gives an excellent summary of the design of the mechanism of a condenser. My paper is intended to demonstrate a basis for rational functional design of heat transfer apparatus of all types for every flow condition, throughout the whole range of variation.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

In the section Air Engineering, attention is called to the article by Prof. Brabbée and Dr. Bradtke on the graphical process for the determination of dimensions of pipes in ventilating and heating systems, developed on the basis of an extensive series of tests. In the same section is reported the beginning of an article on graphical tables for calculating reciprocating compressors. Both articles are interesting as showing a strong tendency toward development of graphical methods for solving engineering problems.

The article by Binder on initial temperatures of combustible gases and liquids is an interesting contribution towards a question of considerable interest to the designers of gas and explosion engines (though it is quite possible that the data indicated therein have been already discounted empirically).

In the section Mechanics, is reported an article on recent tests of the effective forces between driving belt and pulley. Among other things, these tests have shown the fallacy of the idea that the belt delivers a higher frictional resistance in gliding on a rough pulley than on a smooth one.

In the same section is continued from the August Journal the abstract on theory of resistance to rolling of a hard body over a plastic surface.

From a German paper is abstracted an account of experience with coke firing under boilers, indicating some limitations of this kind of fuel, and giving suggestions as to the best methods and most suitable type of equipment.

A discussion of the location of the neutral zone in heated buildings is presented from a paper before the American Society of Heating and Ventilating Engineers.

F. L. Fairbanks before the American Society of Refrigerating Engineers describes the design and installation of a large ammonia compression machine, giving in detail the system adopted for ordering the machinery and its installation. The suction valve of the refrigerating machine is described and illustrated, and some indicator diagrams are given from the ammonia end of the compressor.

The fundamental problems of engine design and formulae for comparison of gasoline and automobile performances are reported from two papers presented before the Society of Automobile Engineers.

From the Journal of the South African Institution of Engineers is taken an abstract of a paper on the influence moisture in air has on mine ventilation. Among other things, the author considers the physiological effect of excessive moisture and gives some rules as to the basic methods of designing mine ventilation systems.

FOREIGN REVIEW

Air Engineering

SIMPLIFIED GRAPHICAL OR ANALYTICAL PROCESS FOR THE DETERMINATION OF DIMENSIONS OF PIPES IN VENTILATING AND HEATING INSTALLATIONS, Professor Brabbée and Dr. Bradtke.

Abstract of No. 21 of *Communications of the Testing Laboratory for Heating and Ventilation*, of the Royal Tech-

nical High School, Berlin (the original communication is not available in the Library of the Engineering Societies). It is devoted to the calculation of high pressure and steam heating and ventilating installations by a method previously established for the determination of the diameters of piping in hot water heating systems.

The following notation is used:

H = Total pressure in kg/m^2

R = Frictional resistance per meter of piping in kg/m^2

Z = Fall of pressure due to single resistances in kg/m^2

L = Volume of air in m^3/sec .

f = Cross section of the passage in m^2

l = Length of passage in meters

v = Velocity of air in m/sec .

d = Diameter of passage in millimeters

g = Acceleration due to gravity in m/sec^2

γ = Specific weight of air in kg/m^3

a = Δ constant

ξ = Resistance coefficient.

In the equation

$$H = \sum_{i=1}^n (R_i + Z_i) \dots \dots \dots [1]$$

all frictional resistance of the air may be expressed by a potential function having the following form:

$$R = \frac{av^n}{d^m} \dots \dots \dots [2]$$

The single resistances are taken care of by the following equation:

$$Z = \xi \frac{v^2}{2g} \cdot \gamma \dots \dots \dots [3]$$

In connection with these three equations, the following is added:

$$L = fv \dots \dots \dots [4]$$

Equation [2] has been derived from the data of a considerable number of investigations reported in technical literature on frictional resistance of air in metal passages. It is based on 293 observations made on passages having a diameter from 19 to 1000 mm., and since a remains constant only for a definite specific weight of air, the corresponding specific weight γ had to be brought in accordance with the conditions existing in the ventilating passages. This was done by means of data on the influence of γ on the air resistance derived from the very careful investigations of Fritzsche. Further were used data obtained experimentally by Rietschel on the flow of air in rectangular sheet iron passages. There were no modern investigations covering the case of brick passages, but it was found that the values obtained from equation [2], when doubled, were in nearly perfect accordance with the values given for brick passages in Rietschel's *Handbook for the Calculation and Design of Ventilating and Heating Plants* (in German). Therefore, the final formula in which the average roughness of the ventilating passages is taken care of by varying the velocity exponent n can be applied both for the round and rectangular sheet iron and brick passages.

Among other things, the investigation gives a table indicating the values which have to be used in the above equa-

tions. There are four more tables covering the following subjects: 1, equivalent diameters and cross-sections of passages for rectangular passages from 0.1 to 2.5 m. length of side; 2, effective pressures in passages 1 m. high, prevailing at various external and internal temperatures; 3, single resistances generally occurring in practice; 4, calibration constants for frictional resistances at γ equals 1.2 and temperatures in the passage varying from 0 to 80 deg. The new method of calculation is illustrated by three examples. (*Vereinfachtes zeichnerisches oder rechnerisches Verfahren zur Bestimmung der Rohrleitungen von Lüftungs- und Luftheizungsanlagen*, Professor Dr. Brabbe and Dr. Bradtke, *Gesundheits-Ingenieur*, vol. 38, no. 28, p. 325, July 10, 1915, 2 pp., p.)

GRAPHICAL TABLES FOR CALCULATING RECIPROCATING COMPRESSORS, Immerschitt

M. Hirsch ("Air Pumps, the Design, Calculation and Testing of Compressors and Vacuum Pumps," in German) was the first to offer a complete method for graphical calculation of reciprocating compressors. His method, however, did not take into consideration losses in the suction

opening of the pressure valves and expulsion of the compressed air from the cylinder. The reexpansion of the air from the clearance space is also taken into account.

When such diagrams are plotted, certain relations have to be taken into consideration. First, compressors equipped with automatic valves are here considered particularly. Further, assumptions have to be made as to the character of the air (whether dry or moist), as to the cooling exponent of the compression and re-expansion line, and as to the dimensions of the clearance of the compressor. In plotting the suction and expulsion lines the speed of the compressor has to be also considered. Hence the diagram does not apply to any kind of compressors, but only to those equipped with automatic valves and jacket cooling, and not to slide valve compressors, compressors with the equalization of pressure, semi-wet and wet compressors. This does not, however, matter much because semi-wet and wet are scarcely built any more, and compressors with automatic valves and jacket cooling are mostly used.

As regards the selection of data of design the clearance space was taken to be 2.5 per cent. Fig. A shows the air diagram for 7 atmospheres absolute air compression com-

FIG. 1. DIAGRAMS SHOWING COMPARATIVE PERFORMANCES OF SINGLE AND MULTISTAGE COMPRESSORS

of air and in its displacement from the cylinder due to the motions of the valves and valve resistances. As a result, in order that the data graphically obtained by the Hirsch method might be used, they had to be multiplied by certain coefficients obtained experimentally.

The present author attempts to offer a graphical method for handling reciprocating compressor problems based on somewhat different principles. In order to obtain tabular values for the single stage and two stage compression and for different end pressures, compressor diagrams were plotted in shape very near those found in actual practice. Fig. 1A shows a diagram for single stage compression and 6 atmospheres gage pressure; and Fig. B a diagram for a two-stage compression with the same end compression. In these diagrams plotted from data found in numerous diagrams taken in actual practice, all the resistances met with in the operation of a compressor with automatic suction and pressure valves, are found to be taken into account, such as losses in opening of the suction valve, taking in of the air, in compression because of the heating of the air,

pressors. In construction of the compression and re-expansion lines the exponent 1.3 was adopted which pre-supposes an effective cooling, without, however, making serious demands on it. The suction pressure is taken to be 5 per cent. below the outside air pressure, while the compression pressure (the use of light automatic valves being assumed) is 0.15 atmospheres higher than in the compression chamber. Multi-stage compression results in lower power consumption of the compressor for the same air output, greater volumetric efficiency, better maintenance of the compressor and drier compressed air. As shown in Figs. C, D and E the most favorable from a technical point degree of compression is attained on the assumption of 7 kg. per sq. cm. end compression, in three stages. In four-stage compression the losses through friction in suction and additional compression in the fourth stage are greater than the gain obtained through the triple return cooling as compared with the double one. If in addition the increased work in piston friction in three stage compression is taken into consideration as well as the additional cost of the second intermediary

cooler, and the higher consumption of cooling water, it is found that the most desirable reciprocating compressor for compression from 6 to 7 atmospheres is the two-stage one.

Hence the tables worked out apply for single stage compression to air pressures of 3-8 atmospheres absolute, and for two-stage compression from 5-20 atmospheres absolute; while the three-stage compression has been left entirely out. Fig. D gives an air diagram for two-stage compression at 7 kg. absolute air pressure.

The diagrams have been plotted in such a way that the work done in low pressure and high pressure cylinders and the end temperatures be equal to one another. Hence the compression ratios in both of them must be equal or both must be equal to the square root of the absolute end compressor. (*Graphische Tabellen zur Berechnung von Kolbenkompressoren*, Immerschitt, *Der praktische Maschinen-Konstrukteur*, vol. 48, nos. 27-28, July 15, 1915, article not finished; abstract will be continued in an early issue.)

Internal-Combustion Engineering

INITIAL TEMPERATURES OF COMBUSTIBLE GASES AND LIQUIDS

For the proper operation of gas, benzole and gasoline engines, the explosion temperatures generated by the combustion of the fuels are of great importance. There is scarcely any doubt that the temperatures as previously computed on the assumption of the specific heats being constant were too low. Therefore the author has recomputed these temperatures, using increasing specific heats, and the difference in results, as shown by Table 1, are quite large.

In accordance with the more modern data on specific heats increasing with temperature, it is found, for example, that the specific heat of 1 cbm of carbon dioxide at 1000 deg. cent. is as follows:

$$1000(0.4886 + 0.00024 \times 1000)$$

Hence the increase of temperature for 1 deg. cent. is equal to $0.4886 + 0.00024 \times t$.

And from this is computed the general formula for the combustion and explosion temperatures:

$$T = \frac{WE}{cbmC(0.4886 + 0.00024t) + cbmH(0.4692 + 0.00015t) - cbmN(0.308 + 0.00007t)}$$

The initial temperatures have been computed with theoretical air volumes and on the basis of combustion with pure oxygen; for explosives such mixtures may perhaps find their application. The temperatures when taken with pure oxygen are at rising temperatures.

In the table the volumes of the explosive mixtures are given before and after combustion, and from this are computed the gage pressures available during explosion. Of considerable interest are the usually small differences in the initial temperatures, which fact the author explains by assuming that what occurs is the conversion of oxygen into carbon dioxide and water vapor. Since, however, the difference in heating value of these two elements in equal contact with oxygen is not particularly great, the initial temperatures also cannot vary very much. The extremely powerful noise occurring during explosion of acetylene is, therefore, due less to the development of a high pressure than to some sort of acoustic action.

Sooner or later these much lower initial or explosive tem-

peratures will have to be taken into consideration in designing gas and explosion engines, unless practice has already discounted these temperatures empirically. Mechanics

RECENT TESTS ON THE EFFECTIVE FORCE BETWEEN DRIVING

BELT AND PULLEY

The law of friction of solid bodies applies fully only to the case of surfaces of belts and pulleys clean and absolutely free of grease and the nearest approximation is the case of new belts having very little grease on them. If on the other hand there clings, more or less perfectly, on the smooth surfaces of the belt and pulleys a thin skin of liquid, then, in accordance with the amount of its adhesion, the magnitude of the effective force varies as the internal friction of the liquid and thus becomes functionally dependent on all other variables, in particular: the effective surface, the gliding velocity, and the temperature and viscosity of the adhering liquid. Under such conditions new forces come into operation, in some cases many times greater than those acting in the case of pure friction between solid bodies. The properties of the belt material become of secondary importance, while the properties and amount of belt grease assume a preeminent importance.

The presence of a uniformly thin and smooth skin of grease on the gliding surface of a belt has a double effect. In the first place, it makes possible the rise of large forces between belt and pulley, especially with increase in gliding velocity. Second, it protects the surface of the belt. In particular for high belt velocities belts should be as flexible, soft and well greased as possible. In the case of a slightly greased belt, the application of a proper belt grease to the clean surface can help in building up a thin skin of grease between the belt and the smooth pulley which raises the effective forces as has been proved by experiments.

When there is a skin of liquid present, the magnitude of the effective forces increases, in the first place, with the gliding velocity. This makes the belt drive stable as regards overloads (up to certain definite limits of this latter): when large peripheral forces have to be transferred, higher gliding velocities must be used, and they lead to increased frictional resistances on the assumption that the temperature remains permanently constant. The average gliding velocity of the belt and pulley increases (all other conditions being the same and peripheral forces transferred being equal) approximately in proportion to the belt speed. In the high speed belts, therefore, usually larger frictional forces are in operation.

The superiority of large pulley diameters and comparatively wide belts, established by experiments, is partly explained by the functional dependence existing, in the case of well greased belts, between the magnitude of the effective forces and that of the gliding surfaces.

With rough surfaces of pulleys the effective force is greater than with the smooth pulleys only when the velocity of gliding is negligibly small. Otherwise it is always smaller, the more so the more perfectly the face of the belt is covered by a thin skin of fluid. As a result rough pulleys not only cut down the life of the belt through increased

wear but do not accomplish the purpose of increasing the frictional resistance in gliding. (*Versuche über die Grösse der wirksamen Kraft zwischen Triebriemen und Scheibe*, A. Friedrich, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, nos. 27, 29 and 30, pp. 537, 580 and 608, July 3, 17 and 24, 16 pp., 39 figs. *et.c.*)

THEORY OF RESISTANCE TO ROLLING OF A HARD BODY OVER A PLASTIC SURFACE, B. B. SCHULTZ

A treatment of the resistance to rolling of cylindrical wheels over various types of ground, considering in particular resistance to rolling of driven wheels. The present article, while an independent unit, is, to a certain extent, a further development of an article previously published by the author and abstracted in *The Journal* August 1915, p. 478.

As regards the resistance to rolling of driven wheels, the author gives in a table the various coefficients (determined experimentally) of resistance of motion of ordinary wagons over horizontal roads of various kinds, compiled from data found by Morin, Résal and Watson. None of these investigations indicates how the resistance to motion varies with the change of diameter of the driven wheels, the width

tion made by the author, the diameter d of the journal does not exceed, in the case of heavy trucks, 60-80-100 mm, and for light wagons 40-50 mm, so that the ratio $\frac{d}{D}$ does not usually reach 0.110 and does not fall below $\frac{1}{30}$, being on the average approximately $\frac{1}{20}$. On the whole, the author

shows that resistance to the motion of the wheel, due to friction in the shaft, does not exceed usually one-half of one per cent. of the load of the shaft and in the least favorable case, does not reach one per cent. of that load.

The resistance to motion due to vibration of the wagon is considered as the entire increase of resistance to motion due to the velocity of motion. The author comes to the following conclusions as to this particular item in the resistance to motion: The variation of the resistance to motion of a wagon with the increase of its velocity is observed only when motion occurs over uneven hard ground where this resistance is great, and in the first approximation, the resistance increases with the velocity, in a straight line. Resistance to motion due to the vibration of the

of their rims and presence or absence of gripping protuberances, and what are the most favorable dimensions of a wheel giving minimum resistance to rolling. In order to answer these questions, the author breaks up the complex phenomenon of rolling into its simplest components, by considering three of its elements: *viz. first*, resistance to motion due to friction in the journals of the wheels of the wagon; *second*, due to vibrations of the body of the wagon, and *third*, resistance of ground to rolling of the rims of the wheels.

The resistance due to friction in the journals of the wheels of the wagon may be considered as a braking force R , kg applied horizontally to the axis of the wheel, and, mechanically, may be expressed by the following formula,—

$$R = \mu \frac{d}{D} \cdot Q$$

where d is the diameter of the journal of the shaft, D the diameter of the driven wheel, Q the load on the shaft in kilograms and μ coefficient of friction on the surface of the journal. According to M. Forestier, this coefficient is 0.1 for ordinary journals lubricated with journal grease, 0.01 for patent bearings lubricated with oil, and 0.005 to 0.0025 for lubricated ball-bearings. According to the investiga-

wagons in the case of motion over uneven, hard ground, at very low velocities, amounts to not more than some tenths of one per cent of the load of the wagon. In rolling over smooth ground, the resistance to rolling of hard tires may be considered as practically independent of the velocity. The resistance to the motion of the wagon over soft ground (subject to deformation), is on the average greater than the resistance to motion over every other kind (hard) of ground, and reaches the maximum absolute value (up to 25 per cent) of the load on the wheels. The resistance to rolling of wheels over soft ground (subject to deformation), is the main constituent of resistance to motion.

The state of theory as regards resistance to rolling is rather unsettled. According to the law of friction in motion formulated first by Coulomb and accepted by Morin, this resistance is proportional to load and inversely proportional to the diameter of the rolling cylinder; according to Professor Hele-Shaw, it is inversely proportional to the square root of the diameter; and according to conclusions drawn from the present investigation, it is inversely proportional to the diameter raised to the power 2/3. Further, the coefficient of resistance to rolling is, according to Coulomb and Morin, independent of the load, while according to tests

made by the committee of the British Association, it decreases with the load. According to tests at the automobile laboratory of Professor Riedler, it increases with the load, and according to the data of the present investigation, it increases with the load slightly and is proportional to the cube root of the load.

The present investigation is limited to the consideration of resistance to rolling of driven wheels moving over a horizontal and plastic roadway. The specific resistance of the ground to crushing is assumed to be proportional to depth y of crushing, so that $f = f_1 y$, where f_1 in kg per cm is the coefficient of specific resistance of the ground to crushing.

If we denote by Q kg the load on the surface of rolling, by R kg the effort of rolling applied to the axis and forcing the wheel to roll uniformly, by B cm the width of the rim and by y_0 cm the depth of the impression left in the ground by

be in equilibrium, and therefore the algebraic sum of their vertical projections must be equal to zero: $\Sigma Y = 0$ or

$$Q - SdF \cos \alpha = 0$$

where $SdF \cos \alpha$ must be spread over the entire surface S of rolling in contact with the ground. But $dF \cos \alpha = B \cdot f \cdot dx$, since $dF \cos \alpha = (F \cdot ds) \cos \alpha = FBd\ell \cos \alpha$; on the other hand, as one can see from Fig. 2 B, $d\ell \cos \alpha = dx$, and hence

$$dF \cos \alpha = F \cdot B \cdot d\ell \cos \alpha = F_1 \cdot y \cdot B \cdot dx \dots \dots \dots [2]$$

which brings the equation to the form:

$$Q = F_1 \cdot B \cdot \int_0^{y_0} y dx \dots \dots \dots [3]$$

The properties of the circle indicate the following (Fig. 2 C):

$$x^2 = [D - (y_0 - y)](y_0 - y) \dots \dots \dots [4]$$

If we differentiate this equation, free it from x and substitute in equation [3], we have then:

FIG. 2 THEORETICAL CURVES OF RESISTANCE TO ROLLING AS COMPARED WITH THOSE OBTAINED EXPERIMENTALLY

the rolling cylinder, then the specific work L_0 in kg per cm required to deform 1 sq. cm of the surface of the ground to a depth y_0 will be in kg-cm

$$L_0 = \int_0^{y_0} f_1 \cdot y dy = \int_0^{y_0} f_1 \cdot y dy = f_1 \frac{y_0^2}{2}$$

and hence the work per unit of length of roadway (1 cm) or the magnitude of the resistance to rolling will be

$$R = \frac{L}{l} = L_0 \cdot B \dots \dots \dots [1]$$

Now (Fig. 2 A) let the origin of coordinates be at O ; the axis of X along the line $O.A$; the axis of Y along the line $O.B$ and the axis of Z normally to the plane of the drawing. If we take an element $dS = B \cdot d\ell$ on the surface of the rolling cylinder, which $d\ell$ is the element MN of the arc AB ; let $dF = f \cdot dS$ be an element of the force of pressure of the ground against the surface of rolling corresponding to dS ; assume f the specific pressure on the ground to be proportional to the depth of crushing y : $f = f_1 y$. If we neglect friction, we by that very fact assume that $dF \perp dS$. External forces applied to a uniformly rolling body, must

$$Q = F_1 \cdot B \int_0^{y_0} y \frac{D - 2(y_0 - y)}{2\sqrt{[D - (y_0 - y)](y_0 - y)}} dy \dots [5]$$

where the fact has been already taken care of that, in differentiation, the signs of ydc and dy are opposite.

It is theoretically possible to solve the complicated integral in equation [5], but practically there would not be much use in doing so. By approximate substitution, the author derives the following two expressions (the numbers of the equations are those in the original article):

$$Q = \frac{2}{3} \cdot F_1 \cdot B \cdot \sqrt{D} \cdot y_0^{3/2} \dots \dots \dots [7]$$

$$\varphi = \frac{3}{4} \sqrt{\frac{3Q}{2F_1 \cdot D \cdot B}} \dots \dots \dots [12]$$

where $\varphi = \frac{R}{Q}$, and is the coefficient of resistance to rolling.

Formulae [1], [7] and [12] give the solution of the problem of resistance to rolling in the case of a cylindrical wheel with a hard rim, moving over a plastic roadway, on the assumption that the resistance of the ground is proportional to the

depth of its deformation. The author shows that the expression for R obtained in equation [1] by means of computing the work of deformation of the ground, may also be obtained from the equations stating the conditions of equilibrium of a rolling wheel, by equating to zero the algebraic sum of the horizontal projections of all forces acting externally on the wheel. From this, he derives the following equations, which give a general and analytical solution of the problem of resistance to rolling of a driven wheel with a hard cylindrical rim, moving along a plastic roadway, this solution being independent of the law of resistance of the ground to deformation:

$$R = B \int_0^{y_0} F \cdot dy \dots\dots\dots [13]$$

$$Q = B \int_0^{x_0} F' \cdot dx \dots\dots\dots [14]$$

Theoretically, therefore, the problem can always be solved, no matter what it is, by the experimental law of resistance of the ground to the deformation. Equations [13] and [14] can be integrated with particular ease in the case when $f = \text{constant} = f_0$; i.e., when the specific resistance of the ground to deformation is constant, in which case

$$R = F_0 \cdot B \cdot y_0 = \frac{Q^2}{F_0 \cdot B \cdot D} \dots\dots\dots [15]$$

$$\varphi = \sqrt{\frac{y_0}{D}} = \frac{Q}{F_0 \cdot B \cdot D} \dots\dots\dots [16]$$

$$Q = F_0 \cdot B \cdot \sqrt{D \cdot y_0} \dots\dots\dots [17]$$

$$y_0 = \frac{Q^2}{F_0^2 \cdot B^2 \cdot D} \dots\dots\dots [18]$$

It is, however, important to bear in mind that, as shown by the author, the law of resistance assumed above has been shown, by the experiments of the author, not to be in accordance with actual conditions. From this, the author proceeds to show the magnitude of error caused by the use of the simplified expression for x^2 in equation [4].

There is no way of easily verifying the correctness of the formulae derived by the author, although theoretically a single typical test, properly carried out, would have been sufficient for this.

The equation for $\varphi = \frac{1}{3} \sqrt{\frac{y_0}{D}}$

derived on the assumption of the resistance of the ground and the depth of its deformation being proportional to one another, foretells the magnitude of the coefficient φ , which is, on the other hand, equal to the ratio of experimental magnitudes, R/Q . If, now, we write in a general form

$$\varphi = \xi \sqrt{\frac{y_0}{D}}$$

we can show by means of the initial equations that ξ depends on the law of resistance of the ground to deformation and, in particular, if the resistance is constant (independent of depth), then

$$\xi = 1, \text{ and } \varphi = \sqrt{\frac{y_0}{D}}$$

From this is obtained a remarkable conclusion, viz., that if the coefficient ξ be determined by means of data obtained experimentally from the equation

$$\frac{R}{Q} = \xi \sqrt{\frac{y_0}{D}} \dots\dots\dots [19]$$

it is possible from its magnitude to judge of the nature of the law of deformation of the ground in the expectation that the smaller ξ is as compared with unity, the more rapidly

will the resistance of the ground increase with the depth of deformation.

From equation [1] for R , it follows that the absolute magnitude of the resistance to rolling of a cylindrical wheel over a given ground is proportional to the width of the rolling rim B and the square of depth y_0 of the imprint of rolling, provided the resistance of the ground is proportional to the depth of deformation. From another equation, it follows that if the resistance of the ground is proportional to the depth of deformation, the specific resistance to rolling of

the wheel $\varphi = \frac{R}{Q}$ is determined entirely by the specific magnitude of the penetration of the wheel into the ground

$\frac{y_0}{D}$. From the same formula, it follows that a relatively deep penetration of the wheel into the ground is a necessary and sufficient index of a large relative resistance to rolling. From equation [12], it follows that for a given wheel and roadway the relative resistance to rolling is not a constant magnitude but one slightly increasing with the load (proportional to $Q^{\frac{1}{2}}$) if the resistance of the ground is proportional to the depth of its deformation. It may be noticed in this connection that experiments in the laboratory of Professor Riedler have shown the practical independence of resistance to rolling of a truck, from the velocity of rolling over a given ground, and also the increase of the relative resistance to motion with the load.

Diagram 2 D gives a comparison of theoretical curves of resistance to rolling with curves obtained experimentally, at the Riedler laboratory, on tests with a truck equipped with iron tires and rolling over wooden boards. This diagram shows, *first*, that the independence of the relative resistance to rolling assumed by Coulomb and Morin in their general law of resistance to rolling, is not true in this particular case since it disagrees with the experimental data to the extent of about 30 per cent; *second*, likewise in the given case is not correct the assumption that the specific resistance of the ground to deformation is constant, since it disagrees with the experimental data to the extent of about 40 per cent. The formula of resistance to rolling of a hard cylinder over a plastic roadway derived above on the assumption of the resistance of the ground being proportional to the depth of deformation satisfied in a manner sufficient for practical purposes the qualitative data obtained from experiments.

Equation [12] shows also that the magnitude of the relative resistance to rolling of a hard wheel over a given plastic roadway increases (slowly) with the load per unit of width of the rim of the wheel, in proportion to $\frac{Q^{\frac{1}{2}}}{B}$ and decreases

more rapidly with increase of the diameter of the wheel (inversely proportional to $D^{\frac{1}{2}}$). A 3 per cent increase of the diameter of the wheel decreases the resistance to rolling by 2 per cent, while an increase of the width of the rim of the wheel by 3 per cent decreases the resistance to rolling by 1 per cent, so that in order to reduce the resistance to rolling, it is advisable to use wheels of larger diameter even though of smaller width. The depth of deformation of the ground decreases slowly with the increase in the diameter of the driven wheels, and more rapidly with the reduction of load from unity of weight on the rim of the wheel; hence, in the interest of the preservation of roads, wide wheels, even though of small diameter, should be used. The author

recommends, therefore, in the interest of road preservation, that the load per unit of width of rim should be regulated by legislation, in accordance with the formula which he likewise suggests.

EQUALIZATION OF MASSES IN MOTOR DRIVEN LOCOMOTIVES AND OSCILLATIONS DUE TO IT. H. Henrich

Discussion of the problem of equalization of masses, or rather, lack of equalization and oscillations due to it on motor driven locomotives. Because of lack of space only a very brief abstract of this interesting article can here be given.

In motor driven locomotives the driving plant consists usually of a horizontal slow-speed single cylinder engine; the reciprocating parts of a driving engine create centrifugal forces directed horizontally while the engine is running. They, in their turn, create forces directed vertically and varying with time as a function of their magnitude, in addition to which the centrifugal forces of the second order are free to act.

Because a locomotive is located elastically on its under-frame, there arise inside the locomotive, on account of the action of the vertical forces, oscillations which are limited only to motions up and down if the driving engine is located so that its axis is in the plane of the centre of gravity of the locomotive. These oscillations in their turn create not inconsiderable additional forces which strain the axes and springs of the locomotives, and put an additional load on the roadway.

The author develops the formulae for the calculation of oscillatory displacements, and of the additional forces acting therein. It is further shown that there is a "critical ratio" between the speed of the rotation of the engine and weight of the locomotive, and the constant of the spring, at which the amplitude of oscillation and the additional forces corresponding to it are theoretically "infinite" and practically "very large." Next it is shown what is the influence of a change in the locomotive springs or the speed of rotation of the engine on the magnitude of the amplitude of oscillations or the additional forces.

The author discusses also the movements due to centrifugal forces of the second order and shows what may be expected in the growth of the oscillatory phenomena if the driving engine be located not in the plane of the centre of gravity of the locomotive; but if, instead, multi-cylinder horizontal engines be used as a driving plant. In conclusion it is shown what type of engines are best to be used in larger sizes of locomotives, whenever a quiet running of the locomotive is considered of really serious importance. Steam Engineering

COKE AS A FUEL UNDER BOILERS, G. Wirthwein

Discussion of the utilization of various kinds of coke as boiler fuel. Both blast furnace and gas cokes are considered.

The average analysis of blast furnace coke is given as follows:

	Per Cent.
Moisture	8.88
Ash	9.81
Carbon	78.02
Hydrogen	0.54
Sulphur	1.03
Oxygen	0.86
Nitrogen	0.86
	100.00

The moisture content of coke varies in accordance with its origin. This variation is sometimes ascribed to moisture taken in by the coke during transportation, but experiments

TABLE 2 ABSORPTION OF MOISTURE BY COKE KEPT UNDER WATER (WATER CONTENTS IN PER CENT)

No. of Sample	Original Water Content	Moisture absorbed after coke has been kept under water for Hours:				
		1	3	6	24	28
1	8	18.2	17	17	15.7	14.4
2	8.5	14.5	13.3	13.3	13.3	13.3
3	6.7	11.2	11.2	.	10.1	8.9
4	10.4	12.6	12.6	.	11.5	11.5

by Dr. Thaler show that this may be so only to a limited extent. Table 2 shows the amount of moisture absorbed by coke after lying submerged in water for corresponding periods varying from one to twenty-eight hours. From these tests it appears that while sample No. 1 has absorbed 10.2 per cent. increase in the other samples was as low as 2.2 per cent. (No. 4) which was probably due to the fact that sample No. 1 was very porous and sample 4 very hard. Dr. Thaler concludes from his tests that in transportation of porous coke even during strong rains, increase of moisture content will not exceed 4 per cent., and with hard coke from 1 to 2 per cent.

The experience of German factories and electric plants with coke firing since the beginning of the war was approximately as follows: It was found that coke alone could not be burned at all on traveling or chain grates. That might have been expected. When coal is burned on this type of grate the ignition of the gases brings the arch to a very high temperature, and as a result coals even very rich in gases can be burned on such grates practically without generation of any smoke. On the other hand, when coke is burned there is no flame at all and as a result the arch remains at a lower temperature. Hence when the coke is moved forward on the grate, it does not find a zone of incandescence, which leads to the fire simply going out. On the other hand, a mixture of three-fourths coal and one-fourth coke can be burned quite successfully on such grates.

The experiments with burning coke on the ordinary flat grate proved far more encouraging as it was found that even pure coke could be burned when the conditions of draft were favorable. This was especially easy to attain with artificial draft such as is produced by a fan or steam jet blower; for example on locomotives even pure coke could be easily burned in large lumps, presumably on ac-

count of the sharp draft there available. In the district of the Bergisch Steam Inspection Association several important concerns have adopted hand firing on flat grates, using a mixture of two parts of coal to one part of coke and without encountering any serious difficulties.

When the coal-coke mixture is fired on the horizontal grate, the fireman must look out for certain particulars. The furnace must be fired up with pure coal of as good a quality as is available; the coal-coke mixture is not used until after the fire has burned up well and is of sufficiently high temperature; and the fuel bed has to be kept somewhat higher than with coal. For a time before cleaning the clinker it is advisable to use unmixed material, that is pure coal, so that the fire shall burn away uniformly, as only in this way are the complaints prevented that unconsumed coke is taken out from the fuel bed with the clinker.

On the whole it was found that the gas coke is a more suitable material for boiler furnaces than blast furnace coke. Large sized coke can be burned on flat grates with hand firing only when a strong draft and a good grate cooling are available, as for example, in locomotives. For firing small coke and coke breeze not mixed with coal, special grate types with undergrate blowers are required. This type of coke can be burned on ordinary flat grates only when mixed with an easily baking coal. In general, it appears however that there is quite a wide field in steam boiler firing where coke can be usefully employed without large and expensive alterations in furnace design being required. RECENT TESTS ON FLOW OF WATER ACTED ON BY A PROPELLER

Description of tests made in the small experimental basin of the Royal Technical High School in Berlin. The outbreak of the war has caused a discontinuance of the tests, but some of the tests have been found to be sufficiently advanced to make it advisable to publish their results. Pitot tubes were used as measuring instruments throughout.

The article describes the experimental arrangements and methods of carrying out the tests and reports in a general manner the results obtained, given in more detail in the form of numerous curves. One of the interesting phenomena observed is the fact that behind the propeller in the region of the hub a very powerful flow of water towards the propeller was found. Continual variations of the water column as high as 170-180 mm have been observed. In the region of the periphery of the hub turbulent motions were found and only near the vanes was the water found to flow backwards. This was the water which was sucked in by the propeller, accelerated in it, thrown back by its motion, and in this way made effective for driving the ship forward.

The greatest velocities of water were found at low speeds within a region extending from 0.25 to 0.75 of the radius of the propeller. At higher speeds of rotation the maximum of water velocity shifts more toward the end of the vanes. Thus at 800 r.p.m., it lies at about 0.6 of the radius all around the propeller; from 0.75 of the radius both the pressure and the velocity curves at nearly all speeds investigated fall off constantly and at about 0.82 radius pass through the

zero line. But beyond 0.82 of the radius there is again found the flow of water towards the propeller. These various velocities of flow are of different strengths at various distances from the axis of the shaft. Thus, for example, at 0.92 of the radius the water column gave the same indication as at 0.98 of the radius. This indicates the presence of eddies at the edges, occurring in addition to the proper propeller flow. Only at a distance of 1.25 radius is there again found quiet water all along the circumference.

All this data has been obtained by measurement over a cross section located about 20 mm behind the rear edge of the propeller blade. Essentially therefore they apply only to this cross section, but since the shape of the "screw water" is nearly cylindrical, these figures apply approximately also to several other cross sections behind the propeller. Fig. 3 gives a diagrammatic view of a possible occurrence of water currents both in front and behind the propeller. Only components in the longitudinal direction are therein represented, so that the values in the direction of maximum flow are not determined and the rotation of the water is not indicated (figure is not drawn to scale).

As regards the flow of water towards the screw in the region of the propeller line, the author believes that it is

FIG. 3. IMAGE OF FLOW OF WATER DISPLACED BY A PROPELLER

permissible to assume that the partial vacuum behind the hub materially affects the efficiency of the propeller. It appears therefore desirable to make the diameter of the hub as small as possible, that is, as small as the strength of material and the method of fastening the propeller blades make it possible. In front of the propeller, that is, in the water under suction, the stream lines are quite different from those in the water under pressure behind the propeller. In the first place the water column in U-tubes in front of the propeller does not rise as high as in the other case; the flow in the opposite direction in the region of the hub cross-section is entirely missing. The influence of the propeller extends over a very much larger cross section; for example, at 7.5 mm in front of the forward edge of the propeller vane at higher speeds of rotation, quite a noticeable amount of water would be disturbed at 1.5 radii.

The rotation of the water filament has been observed here also, just as in previous tests where such rotation was noticed in sand and air. It differs, however, from the rotation seen behind the propeller through the fact that several cylinders of rotation are formed simultaneously. CAN WE LOCATE THE NEUTRAL ZONE IN HEATED BUILDINGS?
J. J. Blackmore

Discussion of the location of the neutral zone in heated buildings; derivation of formulae for the determination of its location, and discussion and consideration of the effect on the neutral zone of the shape of a building.

A neutral zone is a place or a plane inside a room or

FIG. 4 NEUTRAL ZONE IN HEATED BUILDINGS

building where the pressure is equal to that of the air surrounding it on the outside. Its exact location in the room or building depends upon the relative leakages at the ceiling or upper part of the wall or at the floor or lower part of the walls, and under ordinary conditions in still air, its location will be slightly below the central horizontal plane of the room.

In cold weather, the air contained in a heated building is much lighter than the air surrounding it and therefore has a tendency to rise in accordance with the laws of gravitation. Since it is kept from rising by the walls and roof of the building, a pressure is exerted against the ceiling and upper part of the walls. The distribution of the pressure on the walls and ceiling depends, as the author shows, on the location of the openings connecting the inside of the room with the outside cooler atmosphere. Thus, in Fig. 4, with an opening in the side of the room, the neutral zone will be slightly above the center of the opening, and the following formula will apply:

$P_i = h_i + h(d - d_i)$ to obtain the pressure by density.

$$P_i = h_i + h \left(\frac{0.0864 \times 460}{460 + t} \right) - \left(\frac{0.0864 \times 460}{460 + t_i} \right)$$

to obtain (the pressure by temperature) where P_i is pres-

sure above the atmospheric; d density of outside air; d_i density of inside air.

The author derives similar formulae for the case of a zone located at a point below the floor line (this condition being produced by the floor register and the ventilating pipe with a strong draft), as well as for a reverse condition with a ventilating pipe from the ceiling. The above formulae apply to the cases of rooms supposed to be airtight and uniformly heated to 70 deg. when the outside air is at zero.

The author discusses briefly how the location of the neutral zone affects the heating conditions and ventilating system of a building. Its location determines the amount of radiation necessary in the various parts of the building to maintain the uniform temperature on the inside, as well as the ventilating pressures in the building.  Decomposition of Ammonia
 Condensation of Gasoline from Natural Gas
 Boiler Losses
 A. S. M. E. Boiler Code

Extraction of Humidity from Buildings by Refrigeration.

DESIGN, CONSTRUCTION AND OPERATION OF A 1000-TON
AMMONIA COMPRESSION REFRIGERATING MACHINE,
F. L. Fairbanks

Description of the design and installation of a large ammonia compression refrigerating machine, of particular interest because it describes in detail the system adopted for ordering the machinery and for its installation.

The Quincy Market Cold Storage and Warehouse Company of Boston, Mass., had, some time ago, to install a large new unit on a very limited floor space, and the installation had to be made in a short time and under very rigid specifications. No builder could be found in a position to handle the work in the specified time and according to the required standard, and it was decided to design and erect a machine with the company's own men contracting for the individual parts with several of the largest machine, foundry and forge shops.

The contracts were based upon a price per pound for each detailed machine part as per drawing and upon the estimated weights of the designer, and paid on the basis of actual weights of castings as delivered to shop to be machined; on difficult machine work, the prices remained fixed regardless of weight. The company furnished drawings, patterns, foundations, cranes, rigging and men for the erection. The drawings carried the specifications for each different material and, where necessary, the physical and chemical characteristics. All important measurements, standing and running fits, and clearances for expansion as well as running clearances, were shown on the drawings in thousandths of an inch, thus making it possible to have multiple parts machined by different men and in separate shops without reference to each other, and at the same time have them fit together accurately when assembled, as proved to be the case.

The designer was to check, test, and accept or reject each individual piece. The patterns were checked before and after molding. The molds were checked after the cores were in and before closing, and the castings were carefully exam-

med to detect defects before they were machined, all with a view to finding and rectifying errors before they had developed in time and money. This proved an efficient method as there was no part of the machine rejected for defect either in material or workmanship after its arrival at the power plant for erection. The immense pieces to be installed were handled by the company's own men, partly because of the fact that practically all the material had to be carried on cranes over running engines; although the rigging was carefully tested, when parts were passing over some of the larger compressors, a man was stationed at every important steam and ammonia valve with orders to shut it off if he heard a cask: everything went on, however, without any trouble.

The article describes the installation in considerable detail. The apparatus is mainly of standard design, but special attention has been paid to the design of the suction valve (Fig. 5 D) as this feature alone, unless very carefully worked out, will nullify practically all of the benefits to be derived from such an installation. The admission of the high pressure gas from the piston ports is in the nature of an explosion and this at a time when the suction valve is wide open.

FIG. 5 A, B AND C. INDICATOR DIAGRAMS FROM AMMONIA END OF THE REFRIGERATING MACHINE

resulting in a very forcible closing of these valves. Even with large area, low lift, good lubrication and quick action, in a design worked out for known local conditions, smoothness of operation begins to disappear at between 35 and 40 r.p.m. Speeds above 50 r.p.m. are attended with more or less valve slamming, rapidly increasing discharge temperatures and consumption of power.

Fig. 5 A, B, and C are reproductions of diagrams from the ammonia end of the compressor. Fig. A shows the compressor cylinders operating with low pressure gas; Fig. B shows the same with gas from the high-pressure system and Fig. C shows the machine operating with the combined gases. When the gases were combined, the piston ports, as shown by the indicator card, are also large enough to allow of the filling of the cylinder at speeds up to 50 r.p.m. before the piston has reached the end of its stroke. To the very small clearance is probably due the fact that there is practically no re-expansion of gases, it being possible to produce practically square corners on a card by feeding a few extra drops of oil to the cylinders per minute. THE EFFECTS OF END CONNECTIONS ON THE DISTRIBUTION OF
STRESS IN CERTAIN TENSION MEMBERS, Cyril Batho

Investigation of the distribution of stresses in single or built-up structural members and its modification due to different types of end connections.

The paper describes in detail the very interesting method

FIG. 5 D SECTION VALVE, REFRIGERATING MACHINE.

of investigation applied. The peculiarity of the latter lies in the use of a simplified form of Martens' mirror extensometer, constructed in the laboratories of the McGill University, Montreal. This instrument, while very simple in construction and operation, was shown to be capable, when certain precautions are observed in its use, of measuring strains accurately to 1/100,000 in. on a length as small as

2 in., and of being used in the most confined positions, such, for example, as the space between two angles placed back to back and separated by as little as $\frac{3}{8}$ in.

The paper further reports in detail Prof. L. J. Johnson's method of determination of distribution of strains, and among other things, his S-polygon, a figure which gives at a glance the point of maximum bending stress and the value of the latter for any given load axis. The author arrives at the following conclusions:

First. The only practicable experimental method at present available for investigating the distribution of stress in built-up members is by means of some form of extensometer, and the simplified mirror extensometer used in the tests described is very suitable for this purpose.

Second. The assumption of a planar distribution of stress is justifiable in such members as are considered here, except perhaps close to the end connections, and the ordinary theory may therefore be applied to an analysis of the distribution of stress in these members.

Third. In single- and double-angle tension members connected at their ends by means of rivets to wide and rigidly held gusset plates, the stiffness of the gusset plate in its own plane has a considerable effect on the distribution of stress in the member, there being in every case a particular stiffness which will give the least maximum stress in the member for a given load.

Fourth. In such members lock angles are of very little, if any, value for the purpose either of giving a more equable distribution of stress in the member or of increasing the effective length of end connections.

Fifth. A slight change in the line of application of the load to the gusset plates does not materially affect the distribution of stress in the member, except possibly close to the end connections.

Sixth. The experiments on double angles bear out the theory that such members do not act as a single piece bending as a beam (44 pp., 22 figs., *et c.*).

Fundamental Problems of Engine Design, A. P. Brush (abstracted)

A Formula for the Comparison of Gasoline Automobile Performance, Cornelius T. Myers (abstracted)

Motor Vehicle Governors, Theodore Douglas

FUNDAMENTAL PROBLEMS OF ENGINE DESIGN, A. P. Brush

Discussion of the fundamental problems of engine design, mainly with regard to what would be the best engine for a modern automobile.

The author, together with the majority of automobile engineers, assumes that the small-bore, long-stroke, high-speed motor is the best adapted to automobile service, at least pleasure vehicles. This is because it satisfies the two fundamental requirements,—low weight and flexibility. The latter has to satisfy demands through a range unapproached in any other service since if 3 to 60 m.p.h. be accepted as reasonable minimum to maximum road speed on top gear, there is a 95 per cent speed fluctuation and all through this speed range the motors must operate satisfactorily from zero to full power.

As regards the most advisable length of stroke, the author points out that to meet the demands for flexibility, a power curve must be secured that will give good values above 2500

r.p.m. This gives what might be termed the valve-chamber-limit on stroke, because with an assumed form of cylinder and combustion chamber, the valves are limited to an outside diameter slightly less than one-half of the bore of the cylinder and to a throat diameter further reduced by the width of the valve seat.

As regards the connecting rod length, the time-factor as affecting combustion chamber efficiency requires a short connecting rod. The time-factor is most prominent during the latter portion of the compression and the earlier portion of the working stroke. Due to its angularity, the shorter the rod, the less the time proportion of the compression and working strokes coincident with high pressures, high temperatures and high wall-to-volume ratios. Therefore, the shorter the connecting rod the higher the combustion chamber efficiency at any given number of revolutions per minute.

As regards the mooted question of the number of cylinders, the author points out that the problem of increasing the power and flexibility of an automobile on top gear is solved, with the least reduction in efficiency, by increasing the number instead of the size of the cylinders, besides which the frequent impulse engine is more pleasing to the driver in its operation throughout the entire speed range; but there is a price to be paid for it, as there is an increase in mechanical complications. In particular regard to V-motors, the author calls attention to the fact that if all cylinders were worked properly on a single crank throw, all major vertical vibratory tendencies present in the vertical motor would disappear and in their place would be found horizontal vibratory tendencies which are twice as great as the vertical vibratory tendencies of the vertical motor. In the V-12 there are the same major vibratory tendencies as in the vertical 6; that is, instead of a tendency to reciprocate the entire motor mass with four reversals per revolution of the crankshaft, as in the vertical four and V-8, there is a tendency to set up periodic vibrations within the motor mass, the amplitude of these vibrations being in proportion to the work the engine is doing.

In the discussion which followed, C. W. McKinley stated that he had run some tests of two engines of practically the same volumetric capacity, one of which had an almost spherical combustion chamber and the other one pancake shaped which had practically as large a surface as it was possible to make, allowing proper gas flow over the valves. With both of these motors exactly the same horsepower was secured and the speaker therefore believes that the shape of the combustion chamber has very little effect on the ultimate power of the motor.

Victor W. Pagé called attention to the fact that the multiple cylinder engines take very much more time to repair and that for example in valve grinding, the probable expense would be \$2.00 to \$3.50 to grind in eight valves on a four; \$4.00 to \$7.00 for the valves on an eight and \$6.00 to \$10.50 for the valves on a twelve. He believes therefore that the car owners will feel it also after having paid several "twin-multiple" repair bills.

David Ferguson spoke of a test recently conducted by the Pierce-Arrow Company. One of its 2-ton trucks using a standard 4-cylinder 4 by 5 $\frac{1}{2}$ in. engine with a standard worm gear having ratio of 7 to 1, did, on a long run, 7.25 miles per gallon of gasoline. A similar machine with an imported high speed engine of one-half the cylinder volume, geared 14 to 1, was run alongside the standard machine and

did only 6.6 miles per gallon. The speaker asked, therefore, if high speed multiple cylinder engines are more efficient than medium speed 4-cylinder engines, why are the six, eight and twelve high-speed engines not used on trucks, in the case of which economy is of so much moment?

D. McCall White, in speaking of the number of cylinders, urged the development of the small high-speed four, and strongly deprecated the stampeding (of which there is evidence) by some companies who manufacture the lower-priced class of automobiles, into the building of eights. An eight must be of the highest and most expensive type of manufacture. It is easier and cheaper to build a good high-speed four than a bad high-speed eight, and a good four will be more satisfactory to all concerned than a cheap eight. As regards the sixes and twelves, the speaker is of the opinion that, given the same rigidity of bearings on cam shaft and crank shaft, their mechanical efficiency is not so good as that of the four and eight.

Howard E. Coffin stated that the requisite number of cylinders depends entirely on the size of the car. The question is not whether a four, six, twelve or sixteen cylinder engine should be built, but how large the individual cylinder shall be. If the piston displacement is over 300 cu. in. it can properly be broken up into a greater number of cylinders than six, but where the total piston displacement is less than 300 cu. in., it is foolish to break it up into more than six cylinders.

Howard Marmon stated that he had never seen an eight or twelve do things that a six will not do, except possibly some of the "stunts." Speaking of vibrations, he called attention to the fact that the eight cylinder transforms the purely vertical vibration into a horizontal one. The vertical vibration is taken up by the springs, which have a slow period. The chassis is rigid laterally. Any rigid structure will transmit high frequency vibrations as the cross vibrations will necessarily be, and the speaker's opinion was that the cross vibration of the eight was very much more pronounced than the vertical vibration of the four (25 pp., *g*).

A FORMULA FOR THE COMPARISON OF GASOLINE AUTOMOBILE PERFORMANCE, Theodore Douglas

Discussion of a formula which would make it possible to compare various motor vehicles. It gives the following expression for the vehicle coefficient:

$$(A) \quad VC = \frac{8.4nb^2sR}{DW}$$

where n = number of cylinders; b = bore in inches; s = stroke in inches; R = gear reduction; D = diameter of driving tires in inches; W = total weight of vehicle and load in pounds.

In addition to that, VC is multiplied by e_m , which represents the efficiency of the motor compared with the NACC rating as unity, and by e_t , which represents the efficiency of the transmission system, so that the formula becomes

$$(B) \quad VC = \frac{8.4nb^2sR}{DW} \times e_m \times e_t.$$

VC is the ratio of the effort in pounds which the motor can exert at the driving tires to the total weight in pounds to be moved. If multiplied by the weight W , it will give the actual propelling force in pounds exerted at the tires of the driving wheels. VC is the measure of the ability of the motor vehicle to propel itself. It represents the very im-

portant inter-relation of the motor displacement, the gear reduction, the diameter of the driving wheels and the total weight to be moved. The motor speed at any given vehicle speed is determined by the relation of R and D . This formula further affords a ready means of comparing the practical effectiveness or ability of motor vehicles to perform their transportation function.

The terms e_m and e_t may not be definitely known, but can be quite accurately determined experimentally and for the average well-built car the product of these two terms will be about 95 per cent. If this factor be used formula (B) becomes

$$(C) \quad VC = \frac{8nb^2sR}{DW}$$

The author gives the results of applying (C) to a number of well-known cars using W as the weight of the car with full road equipment plus 150 pounds for each person the car is designed to carry. The above formulae are intended to be used primarily for the reduction on high gear, but can be applied to lower gear or intermediate reductions after making allowances for an additional loss in the gear box. The author also considers in detail the various resistance items such as road surface resistance, grade resistance and wind resistance. (7 pp., *g*.)

Test of the Largest Air Compressor, G. M. Clark
The Influence Moisture in the Air has on Mine Ventilation, Arthur C. Whitton (abstracted)
The Centrifugal Pumping Plant of the Durban Roodepoort Deep, Limited, E. G. Izod and A. P. Rouillard

THE INFLUENCE MOISTURE IN THE AIR HAS ON MINE VENTILATION, Arthur C. Whitton

Discussion of the amount of air which has to be supplied per man, the influence of the presence of water vapor on that man and the effects on mine ventilation. As an example, a case is taken for which certain assumptions are made, and it is shown how the amount of moisture affects the results obtained.

The objects of ventilation (in particular, mine ventilation) are, *first*, to sweep all deleterious gases out of the ventilated zone; *second*, to supply to the working places such weight of oxygen as may be required by the workers therein, and *third*, in some cases, to lower the temperature of the working places to such a degree as to make work possible in spots which would otherwise be too warm. The author uses the term "oxygen stuff" to denote the pure dry-air portion, consisting of oxygen and nitrogen, of either dry or saturated air. He compares data on the amount of air breathed in by a grown person hard at work as given by various authorities, but points out that the primary object of ventilation is the provision at every place of such a weight of oxygen stuff as will insure an atmosphere suitable for breathing and not merely a supply of a stated volume of air.

This makes the question of the presence of moisture in the air of high importance, since as the author has shown in tables and curves, under a given barometric pressure, oxygen stuff decreases and water vapor increases in weight per cubic foot as the temperature rises. Further, as the temperature of the saturated air rises, the elastic force of the

water vapor increases, and, therefore, with saturated air at a constant pressure, the elastic force of the oxygen stuff will gradually decrease with increasing temperature, showing the second cause for the decreased weight of oxygen stuff in saturated air. The weight of saturated air is lower per cubic foot than that of dry air at the same temperature and pressure, and with constant pressure and increasing temperature, saturated air decreases in density at a more rapid rate than does dry air. To illustrate the effects of moisture on mine ventilation, the author takes a case for which he makes the following assumptions: *a.* The collars of the upcast and downcast shaft are located on the same horizon, the shafts being sunk to a vertical depth of 3000 ft. and connected by a single drive at the 3000 ft. level; *b.* In each shaft, the mean barometric pressure is 13 lb.; *c.* Mean temperature in the upcast shaft is 90 deg. Fahr., and in the downcast shaft, 60 deg. Fahr.; *d.* The following alternative contents of humidity are assumed as being possible: *first*, the air remains dry during the passage through the mine workings; *second*, the air is kept constantly 100 per cent saturated at all points in its passage, and *third*, the air is dry during its passage through the downcast and saturated during its passage through the upcast shaft.

An investigation of the conditions prevailing in such a case shows that in the event of a constant mean temperature in the downcast shaft and a second constant mean temperature in the upcast shaft, the following rules will hold good: *first*, the least weight of oxygen stuff flows when the air throughout both shafts is perfectly dry; *second*, the greatest weight of oxygen stuff flows when the air in the downcast shaft is perfectly dry, and that in the upcast shaft is 100 per cent saturated; *third*, increasing the degree of humidity of air in the downcast shaft without lowering its temperature decreases the weight of oxygen stuff flowing; *fourth*, increasing the degree of humidity of the air in the upcast shaft without lowering its temperature increases the weight of oxygen stuff flowing; *fifth*, the greatest intensity of draft produced by natural means is obtained when no heat is abstracted from the air itself except in the downcast shaft (i.e., when water is only sprayed into the air into the downcast shaft, which does not mean, however, that the author advocates the disuse of sprays and water blast where these are necessary for the laying of dust or the absorption of deleterious gases).

There is one more aspect to the question of the presence of moisture in the air. It would seem that when a person breathes saturated air at a temperature above blood heat,

there must be condensation of water vapor in his lungs and the resultant water, (almost certainly carrying deleterious gases and matter if the person is in a mine) must have a detrimental effect on the lungs and retard them in the efficient performance of their function. The author thinks that what is generally attributed to "laziness" developed by dark places and the impossibility of continuous supervision, should really be ascribed to the inability of the lungs to handle the extra volume of air which is requisite to provide the necessary weight of oxygen, the lungs being to some extent waterlogged by condensed water vapor and by the moisture which would normally be absorbed by non-saturated air in its circuit in the body, but which cannot be taken up by the saturated air.

The following are some of the further conclusions arrived at by the author:

1. Air should be cooled as much as possible before it goes to the downcast shaft; while it is being cooled, it should be kept as dry as possible unless the heat used to evaporate the water is abstracted from the air, thus lowering its temperature and making it denser.
2. Water having been once used for spraying purposes in situations where deleterious gases are absorbed should not be used again for spraying, as some of the entrained gases will be released to the atmosphere when a portion of the water is evaporated.
3. Carbon dioxide absorbed by the spray water should be removed therefrom before the water goes to the pumps, in order to avoid corrosion in the pumps and piping.
4. If there are ill effects caused by inhaling hot saturated air, the air should be cooled before going to the working places. This could be effected by the installation of small electrically driven refrigerating plants at necessary points in the mine, and passing the ventilating air through cooling chambers. (8 pp., 4 sheets of tables and charts. *per l.*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

NECROLOGY

JOHN BROWN HERRESHOFF

John Brown Herreshoff was born in Bristol, R. I., in 1841. An attack of infantile glaucoma destroyed his sight, but his education was carried on in the schools of his native town. His bent for mechanism revealed itself at an early age, and the handicap of total blindness seemed to serve as a spur to his tireless energy. The miniature craft that he built and rebuilt in those early years served as the foundation of the skill and knowledge that he later turned to such good account.

At the age of twenty, he began the construction of larger craft, and in 1863 he embarked on naval construction as a business, which he carried on for more than fifty years.

In 1872, he entered into partnership with his brother, and together they designed and constructed for the U. S. Government the first torpedo boat, *The Lightning*.

In 1879, Mr. Herreshoff and his brother incorporated the Herreshoff Manufacturing Company, of which he was president and treasurer from its formation to the time of his death.

In 1892, the Herreshoff Manufacturing Company took up the designing and construction of yachts, with special reference to building craft that would enable the New York Yacht Club to hold the trophy against attack. The record of the *Vigilant*, *Defender*, *Columbia*, *Reliance* and *Resolute* indicate to what height of perfection Mr. Herreshoff's firm has carried the science of naval designing and construction.

Mr. Herreshoff was a member of the Institute of Naval Architects of London and a member of the Society since 1884. He died on July 29, 1915.

WILLIAM H. GERRISH

William H. Gerrish was born in Lowell, Mass., in 1865, and was educated at the Lowell High School and the Massachusetts Institute of Technology. He served his apprenticeship at the Lancaster Slate Company, Lancaster, Mass., from 1888-90. For several years he held a position in the drawing room of the Massachusetts Cotton Mills, Lawrence, Mass., and at the Fulton Bag Mills, Atlanta, Ga.

During the Spanish-American War he was associated with the ordnance department of the War Office, Washington, D. C.

In 1899, he became superintendent of Barber Flax Spinning Company, Paterson, N. J., from which he went to the Dolphin Jute Mills, Paterson, N. J. Four years later, he came to New York as superintendent of Commercial Twine Company.

In 1910, he was appointed smoke inspector for the State of Massachusetts, which office he retained to the date of his death.

He was a member of the Order of Masons and the Royal Arcanum. He died on July 15, 1915, in Malden, Mass.

EDWARD THOMAS MORRIS

Edward Thomas Morris was born in Lutterworth, England, in 1863. He was educated in public and private schools in England, after which he served his apprenticeship at Ruston & Proctor, engineers and boiler makers, Lincoln, England, from 1880-1884. During his apprenticeship he took night technical courses.

From 1884 to 1885, he was under instruction at the firm of J. & J. Thompson, marine engineers and boiler makers, Glasgow, Scotland.

From 1887 to 1888, he was outside erector of machinery for the Union Iron Works. From that date until 1899 he was superintendent of the marine engineers department of the Union Iron Works, having charge of the installation of boilers and machinery on the U. S. S. *Charleston*, San Francisco, Monterey, Olympia and Oregon.

From 1899 to 1900, he was assistant to the marine superintendent of the Pacific Mail Steamship Company, and from 1900-1902, general superintendent of the Fulton Engineering and Shipbuilding Works.

During the years 1902-1905, he was superintending engineer of the Oceanic Steamship Company, and in 1906 he became superintendent of construction with the Tracy Engineering Company.

From 1908-1911, he was engineer of construction for the Associated Pipe Line Company. In 1911, he was appointed manager of the Pipe Line Department of the Associated Oil Company, in which position he was in charge of the construction and operation of pipe lines and pumping stations of both companies.

Mr. Morris died in Oakland, California, on May 14, 1915.

GEORGE RIPLEY STETSON

George Ripley Stetson was born in Brooklyn, Conn., in 1837, and was the son of parents who were prominently identified with the anti-slavery and other reforms of the time. His early education was received in Brooklyn, Conn., and in Florence, Mass. His subsequent education was gained entirely through his own efforts without attendance at school.

In 1855, he entered a machine shop in Northampton as an apprentice. After completing his apprenticeship, he engaged in the manufacture of britannia ware. In 1864, he entered the employ of O. F. Winchester, manufacturer of rifles and ammunition, where he remained eight years.

In 1877, Mr. Stetson became superintendent of the Morse Twist Drill and Machine Company, New Bedford, Mass.

While in the service of this company and the O. F. Winchester Company he patented a number of devices which proved of value, receiving thirty-six patents for his inventions.

In 1890, Mr. Stetson became president and general manager of the New Bedford Gas & Edison Light Company.

He was a member of the Sutton Commandery, K. P., and a charter member and past patron of the New Bedford Chapter, No. 49, O. E. S. He was an active member of the National Electric Light Association and the Association of Edison Illuminating Companies, frequently representing these organizations as a delegate, and a charter member of the Society. He died on July 26, 1915.

HAROLD BENTLEY ANDERSON

Harold Bentley Anderson was born in 1878. He received his technical training at the Case School of Applied Science in Cleveland, Ohio, and while in college worked up a motorcycle and also a sewing machine driven by a small gasoline engine. By the time he left college he had completed an automobile and in 1901, he secured patents on two automobiles. He at once entered the employ of the American

Bicycle Company in Toledo, producing a system of double acting brakes and the steering gear that was used on the copy of the "Lifu" truck, made in Toledo.

In 1902, he became associated with The Winton Company as personal engineer for Mr. Winton. In 1904, he was made chief engineer of The Winton Company, which he held at the time of his death.

Mr. Anderson was a member of the Society of Automobile Engineers, American Institute of Metals, American Society for Testing Materials, International Association for Testing Materials, Cleveland Engineering Society, Beta Theta Pi, Theta Nu Epsilon, Cleveland Yacht Club, Cleveland Automobile Club and The Aeronautical Society. He was also an officer of the aero squadron of the First Aviation corps, New York City. He died on July 13, 1915.

PERSONALS

Edwin G. Hatch, consulting engineer, New York, will have charge of the inspection and testing of a 9000 k. v. a. transformer now building at the Westinghouse Electric & Mfg. Company's plant, East Pittsburgh, Pa., for the Victoria Falls and Transvaal Power Company of London. Five similar transformers were shipped to the company's plant in South Africa in 1912.

Dr. Addams Stratton McAllister resigned on August 1 his position as editor of the "Electrical World," New York.

F. M. Feiker, formerly associated with "Factory" and "System" and for the past few weeks with the "Electrical World" editorial staff, will succeed Dr. McAllister as editor of the "Electrical World."

Morris Knowles, consulting engineer, has acquired the engineering business formerly conducted from offices in Pittsburgh, Pa., and Canton, Ohio, by Mr. L. E. Chapin, recently deceased. Mr. Knowles, who was previously associated with Mr. Chapin, will conduct the combined business from his office 2541 Oliver Building, Pittsburgh, continuing to specialize in water works, water power, sewerage, sewage treatment and disposal sanitary investigation, town planning, flood prevention and valuation work.

Joseph A. Whitlow has been appointed chief of the Department of Gas, Electricity, Heat and Water for the Public Service Commission of Missouri. He was formerly chief engineer of the Board of Education of St. Louis.

H. T. Woolson, formerly chief engineer of the Gas Engine & Power Company and the C. L. Seabury & Company Consolidated has accepted a position as truck engineer of the Packard Motor Car Company, Detroit, Michigan.

Frank B. Gilbreth who is conducting a three weeks course in motion study in Providence, R. I., recently held an annual conference with a number of educational men and women from all parts of the country who are interested in the problems of scientific management. The meetings of this year have special significance in that Mr. Gilbreth has been asked by the governments of England, France and Germany to study the problems of efficiency with the view to considering the opportunities which are open to the mutilated soldiers in the present war.

Dr. John A. Brashear, President of the Society, has been chosen by Gov. Brumbaugh as the greatest Pennsylvanian. This selection was the result of an invitation from the officials of the Panama-Pacific Exposition to select a man upon whom the exposition could confer an honor as being eminent in the life of Pennsylvania. The governor not wishing to make the selection himself, decided to let the choice rest with the editors of the state and sent a letter to the journalists asking them to make the selection, and as a result Dr. Brashear was chosen.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 18th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. In sending applications stamps should be enclosed for forwarding.

0205 Draftsman experienced in the designing of bending rolls. One who has actually done work of this character. Location Southern States.

0206 Young engineer for research work of experimental nature, along general methods which have been partially developed. Must have fairly good command of mathematics and particularly adapted to contrive and carry out the mechanical work incident to the experiments. Position offers exceptional opportunities for the development of individual ability. Approximate salary to start will be \$75.00 per month. Location Philadelphia.

0208 Designing engineer in drafting room of Boston concern. Prefer young man with some experience on conveyor work, though such experience is not absolutely necessary.

0209 Salesman for New York concern manufacturing rubber belting and rubber goods for mechanical and manufacturing purposes.

0210 Designer of special and automatic machinery and production tools. Give age, experience, and salary expected. Location New York.

0211 Young engineer with two or three years experience, for work in superintendence and operation of buildings. Location New York.

0213 Two designers with initiative in development work, machinery design, etc. Familiarity with automobile work desirable but not essential.

0220 A capable man, preferably with engineering education and good shop training capable of specifying equipment, to sell metal working machine tools in the Middle West.

0221 A man familiar with presses and forging machinery capable of selling same. Location Middle West.

0223 Department of Mechanical Engineering, Canadian University, invites applications for the position of lecturer in mechanical subjects, mechanics of machines and machine design, or shop practice and laboratory assistant. Applications should be accompanied by a statement of age, qualifications and salary expected.

0225 Mechanical draftsman; some experience in cane or beet sugar refinery; for two or three months work. Salary \$5.00 per day. Location Louisiana.

0226 For firm in New York State, experienced mechanical engineer, who is thoroughly posted in stamping and drawing propositions.

0227 Designer with a broad experience on metal-working machinery and tools wishes to get in touch with a concern which would undertake the manufacture of new line of medium sized machines. Location Middle West.

0228 Draftsman, American; familiar with design and shop work. Position part time in New York State and later in New York City. In applying, state experience, etc. Salary \$100.00.

0229 Inspector of machinery same line as 0228. Apply same as position 0228.

0230 Factory manager of more than ordinary experience in automobile manufacture for a company organizing for manufacture of automobiles. Name confidential.

0233 The direction of fire and patrol service about to be reorganized along most modern lines by a large automobile manufacturing company, is now open to a man who is qualified to take charge, who can shoulder the responsibility of custodian of their huge investment in plants, machinery and stock, with absolute integrity and fearlessness; a sane and healthy view of human nature; alertness rather than suspicion; understanding of various nationalities and types of men and their ways; ability to select a body of good men; to maintain proper discipline and to communicate a large sense of responsibility. Address 0233, care of The Am. Soc. M.E.

0234 A large industrial corporation manufacturing a diversified product including automobiles, desires a works manager for its machine shops, foundries, forge plants and other factory interests. A man of proven ability as an operating executive is sought; his record must demonstrate that his abilities combine a wide mechanical experience with the gift of organizing and obtaining the best from large bodies of men, a selective insight into efficiency methods, an analytic grasp in handling a large mass of detail, a true conception of how and what to delegate and a comprehensive understanding of the problems of the employee. Address in strictest confidence, P. O. Box 450, New York.

0235 Master Mechanic for a cotton piece goods finishing plant. First and principal requirement that he be well educated and preferably a technical graduate. Experience in finishing business not necessary, but ability to handle men and lay out the work of a machine and carpenter shop, piping and electrical department essential. Excellent opening for a man of ambition and energy. Location New England. Apply by number.

0236 Plant Manager for large silk weaving mill, who can lay out buildings and power plant and take charge of maintenance. Apply by number.

0237 Young graduate mechanical engineer to go into heat, light and power department of a plant employing about 1200; will be expected to be able quickly to take charge of the both steam and gas engine departments. Apply by number, giving age, education, experience and salary expected. Location New England.

0238 Young graduate engineer preferably with some experience in machine shop or construction work, to go into the time study and rate fixing department of a large plant in New England; will be expected to learn the business and will then be promoted into the operating departments in an executive office. Apply by letter, giving age, education, experience and salary.

0239 Young man, preferably one who has attended an engineering college, with a knowledge of machine shop practice, to enter the repair department of a large concern as assistant to the master mechanic. Location New England.

0240 Wanted, superintendent for munition shop, one with sufficient experience in the manufacture of six inch (and over) high explosive shells, to design a building, equip it with suitable machinery and operate the same after completion. Plant to be built within 25 miles of New York. Give references as to ability and experience. All communications confidential.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated in consecutive issues of the Bulletin. Names and records are kept on the office list three months, and at the end of such period if desired must be renewed.

I-240 Member, who has designed, built, installed and operated hydraulic, conveying, woodworking, hoisting, computing, combustion, power transmission and other apparatus, mechanical and electrical, wants position with thoroughly established corporation in N. E. or near N. Y. City, in which a good salary may be earned several times over by the sys-

tematic introduction of economies and "short cuts" in men, methods and machinery between coal pile (or water power) and shipping room. Immediate salary of less importance than congenial position in which brains, experience and loyalty will assure fair returns to self and family based on results obtained.

I-241 Works manager or general superintendent, mechanical engineer, graduate of the Mass. Inst. of Technology, with 16 years experience in the manufacture of boilers. At present employed, having charge both of office and shop. Has produced results and can show a clean record. Address through the Society.

I-242 A mechanical engineer, technical graduate, with broad shop and mill experience, desires to become associated with an important New England concern. Full particulars exchanged.

I-243 Technical graduate, with seven years experience in design and construction, desires position with architect or engineer to take charge of service work including power plant, heating, plumbing, lighting and allied branches. Experience in railroad terminals and shops, theater, factory, church and residence work.

I-244 Technical graduate M. E., thirty years old. One year mechanical engineer with railroad. Six years experience with car manufacturer, designing dies, tools, heavy machinery, hydraulic presses; also projectile forgings. Good shop experience. Would be useful as assistant master mechanic or mechanical engineer. Location immaterial.

I-245 Member, age 37, sales engineer technical training, practical mechanic with a successful sales record; speaks Spanish and is conversant with South American trade conditions, forceful Spanish advertising, cataloguing, open for engagement in South American field with a responsible company manufacturing machinery, steel products, hardware or agricultural implements. At present connected with prominent Eastern jobbing house as department sales manager. Salary expected secondary to future prospects.

I-246 Position wanted as foundry superintendent or manager of works doing mostly foundry work; can furnish references satisfactory as to ability from previous employers. Practical foundry man who has filled all positions from laborer to the management of some of the most up-to-date companies in this country. Understands the business end as well as the practical end of the iron and brass foundry business.

I-247 Junior, technical education, with twelve years experience in designing, estimating, constructing and selling all kinds of mining, crushing, cement making machinery and complete plants, desires position.

I-248 Mechanical engineer, college graduate, associate member, 7 years practical experience, 31 years of age, married. Experienced in time study, rate fixing, steam engineer, master mechanic, mechanical superintendent. Salary \$2,400.

I-249 Member, 28 years practical and executive engineering experience in designing, manufacturing, production, organization of manufacture, equipment, etc., modern shop practice and management, desires position as general superintendent or works manager, two or five year contracts only considered. Large experience in precision and quantity manufacture and expert in economical production.

I-250 Member of the Society, with eight years practical experience in general mechanical engineering, and four years experience in the installation of scientific management, wishes a position as efficiency engineer with a progressive concern.

I-251 Junior, age 21, two years at Cornell, two and a half years shop and drafting room experience, wants position in testing, engineering or manufacturing department where there is a good chance for advancement. Willing to work hard and study to obtain advancement. Salary to start, a secondary matter. At present employed.

I-252 Member, graduate Stevens Institute Technology, 13 years experience in design and construction, steam-electric plants, pumping stations, industrial works, heavy foundations, involving pneumatic caisson methods, reports and appraisals, also business experience, is open for engagement.

I-253 Sales engineer with seven years experience in power plant and water works fields; can furnish proofs of ability; would consider a similar position or connection with consulting engineer's office. New York City preferred.

I-254 Associate Member, technical graduate, age 33, nine years shop, erecting, designing and operating experience in the steam engineering field, having specialized in the design and manufacture of steam turbines; capable of taking full charge of same. Location immaterial. At present employed.

I-255 Junior Member, graduate mechanical engineer Stevens Institute of Technology; three years experience and now occupied in fire protection work, engineering and sales; familiar with insurance and factory conditions, desires to associate with insurance company, firm of brokers or insurance engineers having department making a specialty of improved risks. Location in New England preferred.

I-256 Junior member, technical school graduate, with five years engineering experience, 3½ years in present position as assistant mechanical engineer in large government engineering testing plant, desires position with testing department of large corporation, power station or engineering firm; capable of conducting complete tests of steam boilers, engines, turbines and all auxiliary machinery. Would accept \$1800 to start.

I-257 Member, technical graduate, 12 years experience in design and supervision of heat, light and power plants, fuel and combustion, desires position as supervisor of power plants for efficiency, or designer with private corporation or consulting engineer. At present employed.

I-258 Graduate, mechanical engineer, associate-member, 4 years experience in designing, heating and ventilating plants; past 4 years in tests and experimental research work on steam boilers, gas, oil and steam engines, compressors, etc., as assistant professor in mechanical laboratory; at present employed in experimental department of oil engine maker; knowledge of German and French; desires to improve present conditions. Location immaterial.

I-259 Member, Cornell graduate, electrical and mechanical engineer; extensive experience in designing, constructing, operating, maintaining, inspecting, testing, and office engineering; desires position with engineering or manufacturing concern. Employed at present.

I-260 Member, 38, technical graduate, practical experience in various shop departments, also training from draftsman up to executive as treasurer and general manager; particularly well qualified for high-grade sales engineering; solicits opportunities from those seeking a country-wide market for product sold on quality rather than price basis. Has recently tripled volume of sales per dollar expended in repeated instances and has been particularly successful in the comprehensive organization and development of reliable sales forces. Would consider position of general manager if responsibilities were chiefly those of securing satisfactory market. Location immaterial.

I-261 Mechanical engineer, varied experience in technical advertising and editorial work, desires position as advertising manager of manufacturing concern. Location immaterial. At present employed.

I-262 Associate member, graduate of Massachusetts Institute of Technology, five years experience in laboratory and factory, wishes position as assistant to manager, superintendent or production engineer. Now employed. Opportunity first, salary secondary.

I-263 Member with broad manufacturing experience from apprentice to general manager in foundry, pattern, machine, blacksmith, boiler shops and drawing office, positions which

called for initiative executive ability, tact, the handling of correspondence, organization of men and the direction of their work, wishes employment as manager, superintendent or other executive position. Location immaterial.

I-264 Associate-Member, graduate M.E., age 31, married, possessing strong personality with plenty of initiative and executive ability, having had seven years experience in machine shops, foundries, engineering, selling and efficiency work, desires to represent manufacturer in Chicago in a line of a technical nature where hard work and ability will produce a big volume of business. Available Oct. 1st.

I-265 Permanent responsible position wanted by an energetic, thoroughly practical and experienced shop and office engineer; Cornell M.E.; married; successful extended experience in the development of inventions, special and standard machinery, in plant management and as economy engineer.

I-266 Do you need the services of a man with a wide experience in the iron and steel industry? One who has had a good practical knowledge of shop and steel construction, as designer, engineer and contractor, for large independent steel companies, supplemented by three years as inspection engineer in charge of mill, shop and field inspection of structural steel, railroad rails and galvanized product. College graduate; age forty.

I-267 Member just returned from abroad would like to correspond with a well established concern (Middle West preferred) in view of securing a position as tool engineer or chief draftsman in full charge of the designing, building and manufacturing of tools, dies and machinery. Seventeen years experience with four of the largest and best known concerns in U. S. and Europe, on small, accurate interchangeable manufacture. Age 37, natural mechanical and executive ability, full references.

I-268 Junior, graduate, at present employed, five years design, manufacturing and power experience. Wants a live wire position.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.L.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of the Am. Soc. M. E.

ALUMINUM ELECTRICAL CONDUCTORS. Pittsburgh. Gift of Aluminum Company of America.

AMERICA AND HER PROBLEMS, Paul H. B. D'Estourelles de Constaël. New York, Macmillan Co., 1915. Gift of American Association for International Conciliation.

A series of essays based on extensive travels in this country. The author devotes much space to a discussion of economic conditions as he saw them. W. P. C.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Journal, vol. 35, 1914 (2 vols.). New York, 1915.

BOSTON METROPOLITAN WATER AND SEWERAGE BOARD. 14th Annual Report, 1914. Boston, 1915. Gift of Metropolitan Water and Sewerage Board.

COST REDUCTION AMERICA'S ONLY SALVATION. An address by Robert Grimshaw before the American Supply and Machinery Manufacturers' Association, June 4, 1915. Gift of author.

FALL RIVER WATER WORKS. Report of the Watuppa Water Board to the City Council, Jan. 1, 1915. Fall River, 1915. Gift of Fall River Water Works.

INSCHRIJVING VOOR 6625 PAKKEN SUMATRA TAEAK, TE ROTTERDAM, OF ZATERDAG 26 JUNI 1915, IN HET ALGEMEEN VERKOOPLOKAAL. Gift of Universidad Nacional de la Plata.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE. 9th Annual Convention, 1914. Grand Rapids, 1914. Gift of International Association for the Prevention of Smoke.

INVESTIGATION OF THE CONCRETE ROAD MAKING PROPERTIES OF MINNESOTA STONE AND GRAVEL. University of Minnesota Engineering Studies. No. 2. March, 1915. Minneapolis, 1915. Gift of University.

MACRAE'S BLUE BOOK, 1915. *Chicago-New York, 1915.* Gift of MacRae's Blue Book Company.

NEW JERSEY HARBOR COMMISSION. Annual Report, 1914. *Trenton, 1915.* Gift of New Jersey Harbor Commission.

NEW YORK STATE CONSTITUTIONAL CONVENTION. EXERCISES IN Commemoration of the Seven Hundredth Anniversary of Magna Charta, June 15, 1915. *Albany, 1915.* Gift of Constitutional Convention.

ST. LOUIS PUBLIC LIBRARY. Annual Report, 1914-15. *St. Louis, 1915.* Gift of St. Louis Public Library.

SHRINKAGE AND TIME EFFECTS IN REINFORCED CONCRETE. University of Minnesota Studies in Engineering, No. 3. *Minneapolis, 1915.* Gift of University of Minnesota.

TENSILE TESTS. Report made at the Watertown Arsenal, Watertown, Mass., on April 10, 1915. Gift of International Engineering Works, Ltd., Framingham, Mass.

TRADE EDUCATION IN CONNECTICUT. Gift of F. J. Trinder.

UNIVERSITY CLUB. Annual, 1914-15. *New York, 1914.* Gift of A.S.M.E.

WATER SOFTENERS AS APPLIED TO CENTRAL STATION HEATING PLANTS. F. F. Vater. Gift of author.

PUBLISHED MONTHLY BY

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

ANNUAL MEETING, 1915

New York City, December 7 to 10

Textile Session: Papers on the relative values of individual power plants in textile mills and purchased electric current; hot water heating of textile plants, and engineering features of insurance.

Railroad Session: Discussion of trucks for passenger coaches.

Protection of Industrial Workers Session: Papers on safety methods in the engineering industries, compensation laws, economic advantage of safety appliances.

Papers contributed by the Committee on Machine Shop Practice, covering mechanical and electrical control of machine tools.

Papers contributed by the Committee on Industrial Buildings, dealing with building foundations.

Paper contributed by the Research Committee, on mechanical strength of porcelain and stoneware.

Papers contributed by Junior Members for the Junior Prize.

MEETINGS OF LOCAL SECTIONS

October 6, St. Louis, Mo. Subject: The Little River Drainage District, by William A. O'Brien.

October 12, New York. Subject: Motion Study for Crippled Soldiers, by Frank G. Gilbreth, Mem. Am. Soc. M. E.

October 13, Boston, Mass. Joint meeting under the auspices of the A. I. E. E. Subject: Load Dispatch Board as used by the Edison Electric Ill. Co. and Boston Elevated Ry. Co.

October 21, Buffalo, N. Y. Subject: The Training of Young Mechanics, by W. B. Humper, Director of the Pittsburgh High School.

October 27, St. Louis, Mo. Subject: Telescopes, by Dr. John A. Brashear, President of the Society.

November 4, Buffalo, N. Y. Subject: Multiplicity of Cylinders in Automobiles, by J. G. Vincent, Mem. Am. Soc. M. E. and Vice-President of the Packard Motor Car Company.

November, New Haven, Conn. Subject and date of meeting to be announced.

November 19, Chicago, Ill. Subject of meeting to be announced.

THE SAN FRANCISCO MEETING

THE Society was notably represented at the national gathering of engineers in San Francisco last month to pay personal tribute to the builders of the Panama Canal, and its own September meeting was attended by a large proportion of the members resident in San Francisco and by others from all sections of the country. The meeting of the Society took place on Thursday, September 16, and Friday, September 17, three days prior to the International Engineering Congress, which convened on Monday, September 20.

The members of the Society who went out to the meeting from New York journeyed to San Francisco on the Engineers' Special which had been arranged for the convenience of the members of the National Engineering Societies visiting the Panama-Pacific International Exposition and the Engineering Congress. This train left New York on the evening of Thursday, September 9, carrying a party of 169 members of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Mining Engineers and The American Society of Mechanical Engineers, with ladies and guests. The trip across the continent was made over the New York Central and Santa Fé lines, stops being made *en route* at points of scenic interest. Representatives of the various local committees of the Societies came aboard the train before it arrived at Oakland, Cal., to welcome the visitors and to assist in conducting them to their respective hotels. The party arrived in San Francisco on the evening of September 15.

The headquarters of the Society was the Clift Hotel, where registration was begun as soon as the party from New York arrived. The local arrangements were in the hands of the San Francisco committee, F. W. Gay, *Chairman*, F. H. Varney, *Vice-Chairman*, C. F. Braun, *Secretary*, H. L. Terwilliger and J. T. Whittlesey. Acknowledgment of the work of these gentlemen, which resulted in such a successful meeting, should be made.

The opening session of the September meeting was held in the Hall of the Native Sons of the Golden West at 10 o'clock on the morning of September 16, and the

meeting and subsequent events are described in the following communication received from Calvin W. Rice, Secretary of the Society.

"The events since arriving have been the regular morning session on Thursday, opened by the President of the Exposition, Charles C. Moore, extending the welcome on behalf of San Francisco and the State of California, to which President Brashear responded. I have also sent the remarks prepared by Mr. Dickie, in reply to Mr. Moore. The remainder of the morning session was appropriately devoted to two papers bearing on the Exposition, one by Mr. Bayley, chief engineer of construction of the Exposition, who presented a comprehensive paper on the engineering features of its building; and the other by Mr. Dickie, dealing with the features of mechanical engineering interest embodied in the exhibits. After the session we all took busses to the Exposition grounds where a lunch was tendered by the local members. From the Old Faithful Inn, we proceeded in Faggl trains around the Exposition grounds terminating in the Court of Abundance, where the President of the Exposition presented a commemorative medal. This was received by Dr. Brashear on behalf of this Society.

In the evening there was an informal dinner of the Civil Engineers in the Old Faithful Inn, and also a dinner-dance under the auspices of the Electrical Engineers at the Hotel St. Francis, to both of which functions our members were invited. At the latter function the President and Secretary and the Past Presidents of the Mining Engineers and Mechanical Engineers were present as guests of the Electrical Engineers.

Friday, at the professional session in the forenoon, the two papers on Oil and Diesel Engines by Messrs. Goldingham and Adams, respectively, and the one on Gear Teeth by Professors Marx and Cutler were presented, followed by an interesting discussion.

At the conclusion of this session, the Officers of the Society took a bus to the Exposition grounds, where we were the guests at a lunch tendered by the President of the Exposition. There were present, Dr. John A. Brashear, Jesse M. Smith, Geo. W. Dickie, Prof. W. F. Durand, Ira H. Woodson, Gay L. Bayley, Gano Dunn, W. R. Warner, John A. Freeman, W. L. Saunders, H. G. Reist, Chas. Whiting Baker, F. W. Gay and Calvin W. Rice of the Society; Mr. Lynch, Vice-President of the Chamber of Commerce; Mr. Arlett, representing the Governor of California; Mr. Mark-

wart, formerly Associate Director of Works and to whom much of the credit should properly be given for the construction work of the Exposition; Mr. Brown, a director of the Exposition; Col. Hetherington, Pennsylvania State Commissioner; Mr. Conniek, Director of Works of the Exposition; Mr. Hardee, Director of Functions, and the two aides of President Moore, Lieutenant Commander Woodward and Captain Carpenter. Mr. Moore acted as toast master, and after a toast to the President of the United States and the Governor of Pennsylvania, welcome was extended on behalf of the Exposition authorities by Director Brown. Recognition of the engineer was given in connection with the rebuilding of San Francisco after the terrible conflagration, and that the successful completion of the Exposition was due to the Engineer.

Inasmuch as our President, Dr. Brashear, was the person designated by the Governor of Pennsylvania as the most distinguished citizen of that State, mention was made of that fact by Director Brown.

Mr. Arlett, representing the State, followed, and expressed a wish that all the engineers would obtain the vision which the officials had had before them in all their work in connection with this International Exposition.

Col. Hetherington next spoke, having gotten up from a severe illness in order to attend the luncheon. He stated that Pennsylvania had sent to the Exposition two great exhibits—the Liberty Bell and Brashear.

W. L. Saunders, President of the Mining Engineers, was next called upon and facetiously called attention to the fact that this was "Mining Engineers' day" notwithstanding that this luncheon was tendered to the Mechanical Engineers. Mr. Saunders showed the part that mining had played in the development of California's greatness, and in fact, California's contribution to the prosperity of the entire country.

Mr. Gano Dunn, President of the United Engineering Society, stated that while credit should be given the Engineer, we should also remember that it is the artist, the lawyer, and those moved by the religious instinct who should receive recognition, equal with the Engineer, for the imagination essential to the construction of any great work. It was essential for one to have an imagination in order to be considered as truly participating in life. A tribute was paid to President Moore, whom Mr. Dunn had seen three years previous in connection with the meeting then proposed for the International Electro-Technical Commission, and that Mr. Moore had made good his most ambitious promises.

Mr. Dickie was called upon in his capacity as one of our representative engineers, responsible for much of the engineering of the Coast.

Then followed Mr. Markwart, speaking for the engineering staff of the Exposition. He forcefully brought out that the Engineer did have all the imagination essential to the construction and execution of the Exposition—and to the dismantling besides. He had to imagine a lake and a swamp made into a city. In round numbers, the Exposition had cost \$18,200,000, \$14,000,000 of which had been expended under the direction of the engineering staff.

Dr. Brashear concluded the remarks by referring particularly to California's contribution through the Lick Observatory, and particularly urged engineers to have as their main motive of life that of helping others.

President Moore closed the luncheon by a toast drunk to the Progress of Engineering and Scientific Accomplishment.

Quite a number then accompanied President Saunders to the Court of Abundance, where ceremonies similar to those of Thursday were in progress. Director Brown, on the part of the Exposition, presenting a commemorative medal to the Institute of Mining Engineers.

In the evening, the A.I.M.E. held a successful banquet at the Palace Hotel at which the President, Secretary and Past Presidents of the Electrical Engineers and Mechanical Engineers were guests.

Next week are the events of the International Engineering Congress. Besides the professional sessions there will be on Monday evening, the Congress reception, and on Friday evening the Congress banquet.

On Wednesday, in honor of Dr. Brashear, they are to have "Brashear Day" at the Exposition, when we understand a medal will be presented to Pennsylvania's most distinguished citizen.

Friday, will be "Engineer's Day."

CALVIN W. RICE, Secretary.

September 18, 1915.

REPLY TO ADDRESS OF WELCOME BY CHARLES C. MOORE.

BY GEO. W. DICKIE, MEM. AM. SOC. M. E.

The duty of replying to your very kind address of welcome, devolves upon me as Vice-President of this Society. This, sir, is not the first meeting of this Society in San Francisco. On May 16, 1892, this Society began a memorable meeting in the reception parlor of the old Palace Hotel. There the members were welcomed to the Pacific Coast by his Honor, Mayor George H. Sanderson. Mr. Robert W. Hunt replied in graceful terms, and thus the meeting was formally opened. The local committee who made the arrangements for that meeting were Wm. R. Eckart, Chairman, Charles G. Gale, Secretary, G. W. Dickie, James Spiers, John Richards, Marsden Manson, E. J. Molera, H. J. Small and Frank Van Vleck. Some of these have answered to the last call, while the others are still doing something to help along the things they think should never go to the scrap heap. It is very fitting, sir, that you should bid us welcome at this time, as we are here like many others to help celebrate the greatest engineering achievement of our time, the cutting in two of the Western Hemisphere, joining the two great oceans of the world, forming a new pathway for the world's commerce. Our great Exposition that celebrates the completion of this great work, has developed into a thing of wondrous beauty, with you, sir, as its guiding head. It is true that another engineering society will naturally claim first honors in the great work that we celebrate, yet it must never be forgotten that the civil engineer can not go very far in any work he undertakes without the active help of the mechanical engineer. If he wants to dig either a big or little ditch, and needs a shovel for the purpose, either an ordinary 25 lb. hand shovel or a fifteen ton steam shovel, he must get the mechanical engineer with him before he can do any digging, and at this time it is worth while remembering that nearly all the great work carried out under the civil engineer is necessary, because of what the mechanical engineer has been doing. The great steamships that originate with the mechanical engineer, made the Panama Canal a necessity. The locomotive engine, with its long line of cars, makes necessary the tunnels and bridges that the civil engineer constructs for their passage. In fact,

nearly all great modern works of which the civil engineer is so justly proud, have been produced in order that the work of the mechanical engineer may either run over or through them. The work of the civil engineer is more spectacular and more in the public eye, thus exciting admiration that is reflected on the designer and builder.

Sailing on one of the Hudson River day steamers, up that splendid river about two years ago, I saw ahead an airy structure spanning the river at a great height, looking like a huge spider web, too attenuated in appearance to serve any practical purpose, but as the boat came nearer, the stability of this structure became more apparent, and admiration of the boldness of it began to take possession of my mind, then something appeared at one end of this airy structure, and quickly took possession of it as a pathway to the other side. Here was the explanation of it all. The mechanical engineer needed the Poughkeepsie Bridge for his locomotive and train to cross the river, and he also needed the river for his steamer, and so we find as we contemplate the work of these great branches of engineering, that they are "Useless each without the other." The one is static, that is engineering in repose, the other dynamic—engineering in motion, and they are every day becoming more important factors in the work of the world. Even war has now become largely a job for the mechanical engineer, and seeing that we can neither live comfortably, nor die bravely without the help of the mechanical engineer, his position among the useful elements of society should be improved, so that he would occupy a place in the estimation of his fellow men commensurate with the indispensable character of the service he renders to the world. I would not seek a higher place for the mechanical engineer than that which is freely granted the civil engineer, but it should not be lower, and it is one of the functions of the Society that I represent here today, to help the mechanical engineer find his true place among the professional men of his time.

To the 6,000 members of this Society, the country is largely indebted for the position she occupies among the nations of the earth, that she is able to furnish other nations with so many implements through which progress is made, is largely due to the work accomplished by members of this Society. That the reward that comes to them financially is not what it ought to be is shown by the small percentage of our members who have been able to cross the continent, and see the wonderful dream that has become a fact, sir, under your direction—and attend the meetings to be held here. This is to be regretted, but cannot be helped. Engineers as a rule do not acquire wealth, and perhaps it is just as well for them that they don't—there would be less good work done if it were better paid for. The best work that has ever been done for this old, ungrateful world of ours, was never paid for. You can't do the things that you think ought to be done, if you wait for a contract insuring pay before you do them. Many noble engineers still do the things they love to do without any thought of pay, and so long as that is the case, we can well be proud of our profession. The present President of this Society is a splendid example of the character of man I refer to. It has often been said of the family I belong to, that they would rather build ships and starve, than do anything else and become rich, and I trust they will continue in that frame of mind. And now, sir, accept the thanks of this Society in the welcome you have given us to San Fran-

cisco, and in behalf of the members, here present, and the great number belonging to us all over this great country, we thank you very cordially for giving us your presence this morning, and for the kind words you have spoken to us on this occasion.

PRESENTATION OF COMMEMORATIVE MEDAL, THURSDAY, SEPT. 16TH

On behalf of the Exposition, President Moore presented a commemorative medal to the Society in recognition of their having held their meeting in this City at the time of the Exposition. Opening remarks were made by Mr. Dickie, Vice-President of the Society, in which he emphasized the obligation of the world to the engineer. President Moore responded stating that as an engineer this was a hey-day of the Exposition and he expressed great satisfaction in being able to meet members of the Engineering Societies personally.

The Exposition was under great obligations to the Engineering Societies indirectly, and to the members of his staff, directly, for much of its success and beauty.

*"God made the World, but the Engineer
made it to live in."*

One definition which appealed to Mr. Moore was that in our constitution "To adapt the achievements of arts and science to the use of man." President Moore stated that the purpose of the Exposition is to leave enduring high aspirations and high thoughts for the advancement in human brotherhood. The success of the Buffalo Exposition can be credited largely to Mr. Newcomb Carlton, an engineer, and similarly all the activities of this Exposition have been directed by engineers, in fact, the profession dominated the Exposition.

Dr. Brashear responded with heartfelt appreciation. He referred particularly to the monument to Samuel Pierpont Langley, which he had seen on the way to the Court of Abundance. He spoke of the progress of engineering and compared it to the strides in the art of photography. He had had a conversation, when a young man, with a woman who had sat sixty minutes for her photograph, and it wasn't so long ago when one had to sit seven minutes. Now we can not only take a photograph of the cannon ball going through space at the rate of 1500 ft. a second, but also can finish it quickly, as emphasized on this occasion, where a photograph of the company assembled had been taken and prints distributed before the ceremonies were concluded.

The work of the world is yet to be done. Sir Isaac Newton, at the time he was dying, stated that he was as a child who had simply gathered a few shells, whereas the whole ocean of truth lies before us.

After Dr. Brashear's response, Professor Durand followed with an address on the progress of mechanical engineering in the service of humanity.

PROGRESS IN THE FIELD OF MECHANICAL ENGINEERING DURING RECENT YEARS

By W. F. DURAND, MEM. AM. SOC. M. E.

I take it that, in its deeper significance, the ceremonial in which we are assisting this afternoon, is intended to signalize the work of the mechanical engineer in the service of humanity, and in this thought I shall refer briefly to some few of the larger fields into which we are called in this service, and to some of the more important achievements which have been made in these fields.

First in answer to the broad query, What is the field of service of the mechanical engineer? I like to picture him in mind as a great high priest of Nature whose duty it is to stand between the mighty stores of energy which she holds for the service of humanity, and the insistent demand for energy and more energy, as the one universal and essential element in the fabric of our present day civilization.

We have heard in history of the age of stone, the age of brass, of iron, of gold; but in a very real and literal sense the present is the age of energy, an age in which the entire fabric of our civilization is built upon the liberation and utilization of the inorganic agencies and energies of nature.

Pause only for a moment to consider our state, were there available for our present day life, no energy other than that which we might furnish by our own hands, or by the aid of domesticated animals. Consider the essential elements of our everyday life; the raiment we wear, the food we eat, the houses in which we dwell, the means for carrying on the complex systems of intercommunication between man and his fellow. Remove the supply and the methods and means for utilizing the energies of Nature for these purposes and what have we left? Our entire present civilization with its wonderful achievements and complex interrelations, crumbles away and disappears.

And so it is that peculiar function of the mechanical engineer to stand as the interpreter and the purveyor of natural energy in the service of humanity.

The sources of such energy are well known. Those with which we are chiefly concerned are, on the one hand, the hydro-carbon supplies, now existing in the form of gas, oil, or coal, and stored up in past geologic ages for our present day service, and, on the other, hydraulic sources, representing the present day energy of the sun in hitting the water into the air in the form of vapor, whence it is precipitated as rain or snow, collected on high mountain watersheds and ultimately, in seeking its lower level in the sea, may be made to turn our water-wheels and thus furnish energy in electrical or mechanical form as we may desire.

Again in serving the needs of civilization as the interpreter and purveyor of energy, the functions of the mechanical engineer are manifold and not easy of rational classification. Broadly, however, his field of work may be indicated under the following chief heads:

(1) The transformation of energy from the unavailable form in which Nature holds it, into the directly available or dynamic form as embodied in the motion of a prime mover such as a steam or internal combustion engine, steam turbine, or water-wheel; and the design, construction, and application of prime movers in special forms to the driving of steam ships, railway trains, or other special and direct modes of application.

(2) The transformation, by means of devices and mechanisms, of the mechanical energy furnished by a prime mover, into modes of motion suited to the manifold demands presented by the various industrial arts. Thus every machine driven tool for the forming of parts of other machinery or of structures, every mill and factory wheel, in short every cunning device of industry—all represent the application of a mode or means of transforming and thus utilizing mechanical energy.

(3) The organization and management of industrial systems, whereby, through the combination of mechanical energy, raw material and human directive agency, the products of the arts and industries may be most effectively provided.

While the work of the mechanical engineer is by no means hemmed in by the arbitrary boundaries indicated in these categories, and while either along or in co-operation with his brother engineers in other fields, he renders signal service to humanity, nevertheless the three categories noted above represent his most significant and characteristic fields of work and I shall refer, only briefly, to some of the notable achievements in these fields during recent years.

In the broad field of power development, the mechanical engineer has rendered some of his most impressive and beneficent service to humanity. In the transformation of the energy from hydrocarbon sources into mechanical form, there are two well known routes—that by way of water in the form of steam as an intermediate agent, and direct, as in the more recent internal combustion prime mover.

The present steam boiler represents a wonderfully refined engineering product. Having in view the conditions under which it must work it represents indeed a marvel of safety and efficiency. So long as we are limited by the present modes of combustion and heat transmission, the present efficiencies of 80 per cent. and upward leave but small margin for improvement. The special lines of advance during the past decade have been in the use of higher steam pressures, more reliable and effective means of producing superheated steam, a close and intensive study of boiler operating conditions resulting in marked advance in capacity, efficiency, and reliability; and finally, marked advance in our understanding of corrosive and deteriorating agencies, and in effective modes of control.

The reciprocating steam engine, as a prime mover, represents mechanically, in its present form, well nigh a completed and perfected mechanism. While in large sizes the turbine is becoming the typical steam prime mover, and while the internal combustion engine now occupies a considerable part of the prime mover field, nevertheless the reciprocating steam engine still holds its own for many purposes, and aside from the automobile engine is undoubtedly more numerously used than all other forms of prime mover combined.

The special lines of development which have signalized the progress in recent years have included the following items:

(1) Better adaptation to the use of superheated steam.
(2) The advent of the una-flow type of engine with a single cylinder, rivalling the results to be obtained by multi-stage engines using the older mode of steam distribution.

(3) Compact and highly efficient small steam power plant units of the so-called locomobile type.

(4) A careful study into and a better understanding of the conditions which determine the economical selection of

steam prime-movers, thus assuring wiser and more economical choice among the many types offered.

In the field of the steam turbine, the mechanical engineer with his brother the electrical engineer have produced, during the past two decades, a complete revolution in the field of power plant engineering, especially as applied to large central station service for electric light and power, and to marine propulsion in both the mercantile and naval services. Huge units are now possible, which a few years ago were far beyond the dreams of power plant engineers, and give at the same time efficiencies hitherto unattainable in steam prime-movers. The steam turbo-electric unit of 30,000 kw. has already arrived and a larger unit of 50,000 kw. is already peeping above the horizon. The progress in this particular part of the field stands out as a bold mountain peak, and when the history of the development of engineering during the early part of the 20th century shall be written, the advance in the application of the steam turbine will furnish one of its most impressive chapters.

No less significant and impressive has been the progress during the past 20 years, and in particular, during the past decade, of the internal combustion engine—the engine which uses gas, gasoline, distillate, kerosene, or crude and fuel oils as its own immediate source of energy. The automobile with all that it means to the world of today, depends for its present widespread service, on the successful solution of the problem of the internal combustion engine. Likewise the aeroplane, and indeed the entire field of heavier than air aeronautics, depends for its very existence on the marvelous refinements which have been wrought in the design of this form of prime mover during recent years. Again, unknown thousands of industrial, economic, and commercial demands for power in relatively small amounts are met effectively and reliably by engines of this type. Again and perhaps no less impressive than the advent of the automobile engine, has been the rapid development during the past decade of the Diesel engine—the engine which carries the prime mover back to the mouth of the oil well or in any case to a form of fuel of the same order of cost as the crude petroleum oil and which gives at the same time a thermal efficiency reached by no other class of heat prime mover. This engine is making rapid and significant progress in stationary practice where power is required in moderate amounts and where overall economy of the order of the steam-boiler steam-turbo plant must be equalled or bettered.

Still more spectacular is the progress of this type of prime mover in the field of marine engineering. Diesel engine power plants for marine propulsion of a horse power capacity in the thousands are now a commonplace of the field of marine construction, while the submarine, with its terrible powers of offence is dependent for its high surface speed, for power to charge its storage batteries for submerged cruising and for its relatively extended radius of action, on the power developed, and the efficiency realized by Diesel engines as perfected in recent years.

Again, in this connection, I should not omit to refer to the magnificent work which has been done in the field of railway engineering, in the improvement of the locomotive, the iron horse which draws our trains with their millions of passengers and countless tons of freight over the railroads which girdle the inhabited land. In recent years the improvement here has been in refinement of design, improvement in economy and great increase in size and capacity. No more im-

pressive sight perhaps is to be found in this Exposition, in the display of engineering progress, than the two locomotives, in the transportation building, one marking the early pioneer days and the other a modern representative giant of the iron rail.

In the same field likewise, the mechanical and electrical engineer have joined hands and have produced the wonderful electric locomotives now coming into use for special conditions of service, and of which we have in this Exposition a splendid example, nearly the steam locomotives to which I have just referred.

Turning for a moment to the field of hydraulic power engineering, we find in recent years progress, perhaps less spectacular than in some others, but none the less real. The improvements here are concerned with great increase in size, in efficiency, and in general reliability and adaptability in the various fields of service. Here again, joining hands with the electrical engineer, hydro-electric units of 15,000 to 20,000 h.p. capacity and upward, are readily built under suitable hydraulic conditions, and with hydraulic efficiencies close to about 90 per cent—achievements which 20 years ago would have seemed quite beyond the limits of possibility or immediate hope.

But I must hasten on to a few references to achievements in other fields of activity.

In the general field of devices and mechanisms for transforming and utilizing energy in accordance with the demands of the arts and industries, the imagination is staggered by the wealth of material and it is scarcely possible to know where to begin or where to end. One of the notable lines of progress has been in the field of automatics; mechanisms which seem scarcely less than human, and which, in the field of industry, eliminate or reduce to the barest minimum the residuum of human energy or directive agency required, and thus give us the manufactured article as a combination of little beyond raw material and mechanical energy. Again, to take here and there at hazard a few illustrations, mention may be made of the linotype and monotype machines for typesetting, the wonderful printing presses which give us our newspapers, magazines, and books, boot and shoe machinery which has revolutionized this industry in recent years, wonderful looms of the Jacquard type which weave articles of beauty and utility from the raw materials which are supplied, flouring machinery, sugar machinery, wood working machinery, metal working machinery of every kind and purpose, rolling mill machinery for making the steel plates and shapes of which are formed our ships, our bridges, our giant buildings, the rails on which our railroad trains may safely run, machinery for making pipe, tubing, rods, wire—in iron, brass, copper, and in the myriad forms, sizes and patterns which the modern arts and industries require.

These and countless more are all embodiments of ways and means for transforming and utilizing energy, and they represent one of the most diversified and most fruitful of the fields in which the mechanical engineer may serve his day and age. In all of these countless mechanisms, recent years have witnessed signal advance in scope, in adaptation, in economy, and in effectiveness relative to the ends in view.

Turning now, in closing, to the last field which I have mentioned, the organization of industry with reference to the highest economy of useful product, we find most notable advances during the past decade.

The so-called science of industrial management has at-

tracted increasing attention during recent years, and has been the subject of exhaustive studies on the part of many most eminent engineers.

In the accredited pioneer and distinguished leader in this field of work, The American Society of Mechanical Engineers, recognizes one of its own past presidents, Mr. F. W. Taylor, unhappily cut down in the midst of his usefulness in this field.

This is neither the time nor place to discuss in detail the science of industrial management and I can only say here, that as an ideal, it strives to so co-ordinate and combine the duties and responsibilities of capital and of labor, of the highly trained technicians and of the craftsmen in their various grades and degrees of skill, that the products of industry, representing the combination of (1) raw material, (2) human energy and directive skill, (3) mechanical energy, may be realized with the minimum demands on each of these three ingredients, and with the maximum financial reward, fairly divided among all who have contributed to the result.

In this field much of the fundamental work has been well started; much still remains to be accomplished. It is one of the most significant of the fields which have recently attracted the attention of the mechanical engineer, and the past decade will go down in the history of engineering progress as that which witnessed the special groundwork studies which should serve for the development of a wiser and more effective organization of our industrial agencies and forces.

In closing, I only repeat in other words my opening thought. The work of the mechanical engineer enters as an essential element into the daily life and well being of every dweller within the pale of civilized society—whether in sickness or in health, whether high or low in estate, rich or poor, and whether occupied in business or pleasure. It forms that part of the civilization of today which in a peculiar sense renders it distinctive and marks it out from the civilization of earlier ages.

In all this the mechanical engineer should recognize only an opportunity for service to humanity and to the cause of human progress. As mechanical engineers, let us see that we live up to the full measure of the opportunities for such service which are placed in our paths.

In the period remaining between the closing of this session and the International Engineering Congress, the members of the Society took part in a number of excursions to points of engineering interest, including the San Francisco High Pressure Fire System, the Portrero Gas Works, Station A of the Pacific Gas & Electric Co., the Spring Valley Water Works, the Great Western Power Company's Hydro-Electric Development on the Feather River, and dredging at Oroville, and the Spaulding-Drum Development of the Pacific Gas & Electric Company.

The International Engineering Congress opened its sessions on the morning of September 20. The proceedings of this Congress will be described in the next issue of The Journal.

The thanks of the Society are due to W. R. Cobleigh, who attended the September meeting, for the copy of the address by Prof. Durand sent to New York in time for publication in this issue, and to all others who contributed to the success of the September meeting.

CORRESPONDENCE DEPARTMENTS FOR THE JOURNAL

The Journal publishes from month to month papers given at the annual and spring meetings and at many meetings of the local sections of the Society. Discussion upon these papers, however, is not restricted to the meetings. In order to secure the greatest possible benefit from the knowledge and experience of the membership, the discussions given at the time the papers are presented must be supplemented by contributed discussions from those who were unable to be present when the papers were read.

Accordingly, the Publication Committee has authorized a correspondence department for discussions upon technical subjects relating either to papers that have already been presented to the Society, or to new matter, to which contributions are solicited. Comments on papers, brief accounts of new or original methods, and inquiries with regard to engineering problems may properly come within the scope of this department, which it is expected to make a permanent feature of The Journal.

In addition to a section devoted to technical discussion, it has further been decided by the Committee to inaugurate a section devoted to communications containing suggestions by the membership, of any kind or nature for increasing the usefulness of the Society to the community and to the individual. Brief letters for this department are also solicited in the belief that they will prove a helpful means for the guidance of the Society, in extending its activities among the membership.

THE ANNUAL MEETING

The Annual Meeting of the Society will be held in the Engineering Societies Building in New York from December 7 to 10 and even at the present early date the prospects are that the meeting will be one of the best in the history of the Society.

The Officers and Council especially urge members not resident in New York to come to the city if possible at the time of the Annual Meeting and take part in the deliberations.

Arrangements have been completed for sessions by the Sub-Committees on Railroads, Textiles and Protection of Industrial Workers, and for papers contributed by the Committees on Machine Shop Practice and Industrial Buildings, besides unclassified papers, many of unusual interest. In addition to the professional and business sessions and the President's reception, it is planned to hold a smoker.

REPORT OF THE NOMINATING COMMITTEE

As previously announced in The Journal, the Nominating Committee has reported the following names as candidates for the offices indicated:

For President:

D. S. JACOBUS, New York

For Vice-Presidents:

WM. B. JACKSON, Chicago, Ill.

J. SELLERS BANCROFT, Philadelphia, Pa.

JULIAN KENNEDY, Pittsburgh, Pa.

For Managers:

JOHN H. BARR, New York

JOHN A. STEVENS, Lowell, Mass.

H. de B. PARSONS, New York

For Treasurer:

WM. H. WILEY, New York

F. W. TAYLOR MEMORIAL MEETING

The Society to Promote the Science of Management issues a cordial invitation to all persons interested in scientific management and the work of the late Frederick W. Taylor to attend the special meeting to be held as a memorial to Mr. Taylor at 8.15 p. m. on Friday, October 22, in Houston Hall, University of Pennsylvania, Philadelphia, Pa. The program includes the following list of speakers several of whom were closely associated with Mr. Taylor in the vital periods of his career and important phases of his work: Rudolph Blankenburg, Mayor of Philadelphia; Carl G. Barth, Louis D. Brandeis, James M. Dodge, Edgar F. Smith, Provost of the University of Pennsylvania; Henry L. Gantt, Harlow S. Person and Sanford E. Thompson. Distinguished leaders of the scientific management movement in foreign countries have prepared appreciations which will be read.

The secretary of the society, Professor Henry W. Shelton, Hanover, N. H., will be glad to furnish information regarding this meeting to any members of the Society who desire it.

NAVAL ADVISORY BOARD

As announced in *The Journal* for August, the Society was honored by an invitation from the Secretary of the Navy, the Honorable Josephus Daniels, to participate in the work of the Naval Advisory Board, recently created with Thomas A. Edison, Hon. Mem. Am. Soc. M. E., as Chairman, by the appointment of two representatives on the board. In the endeavor to select for representatives men of foresight and executive ability in combination with inventive talent, a ballot of the Council has been taken, and the members to be thus honored are as follows: William Le Roy Emmet of the General Electric Company of Schenectady, N. Y., and Spencer Miller, of the Lيدgerwood Manufacturing Company of New York City and member of the Council.

Invitations were extended to eleven engineering and scientific societies to be represented on the board, as follows: The Aeronautical Society of America, the

American Chemical Society, the American Electrochemical Society, the American Institute of Electrical Engineers, the American Institute of Mining Engineers, the American Mathematical Society, the American Society of Aeronautic Engineers, the American Society of Civil Engineers, The American Society of Mechanical Engineers, the Inventors' Guild, and the Society of Automobile Engineers. Two representatives have been chosen from each of these organizations with a view to obtaining the most advanced thought and experience in the various lines of engineering activity and scientific research.

Mr. Daniels has recently announced that the nominations of the eleven societies have been accepted, forming a board of 23 members including the chairman. The first general meeting of the board has been called for Wednesday, October 6th, at which the work will be organized and methods of procedure determined. The appointees are as follows:

Thomas A. Edison, Hon. Mem. Am. Soc. M. E.,

Chairman

Lawrence Addicks, Mem. Am. Soc. M. E.

L. H. Backeland

Howard E. Coffin, Mem. Am. Soc. M. E.

Alfred Craven

William Le Roy Emmet, Mem. Am. Soc. M. E.

Peter Cooper Hewitt

A. M. Hunt, Mem. Am. Soc. M. E.

Benj. G. Lamme

Hudson Maxim

Spencer Miller, Mem. Am. Soc. M. E.

J. W. Richards

Andrew L. Riker, Mem. Am. Soc. M. E.

Thomas Robins

Wm. L. Saunders, Mem. Am. Soc. M. E.

Matthew B. Sellers

Elmer A. Sperry, Mem. Am. Soc. M. E.

Frank J. Sprague

Benj. B. Thayer

Arthur G. Webster

W. R. Whitney

Henry A. Wise Wood

R. S. Woodward

WILLIAM LE ROY EMMET

William Le Roy Emmet, one of the appointees of the Society, was born at Pelham, N. Y., July 10, 1859, son of William Jenkins and Julia Colt (Pierson) Emmet. He was educated at schools in Canada, New York, and Maryland, and subsequently entered the United States Naval Academy, where he was graduated in 1881. He served as a cadet midshipman until 1883 at Annapolis and on board U. S. S. Essex, and re-entered the navy as junior lieutenant in 1898, serving as navigator on the U. S. S. Justin during the period of the Spanish war. His principal civil employment has been with the Sprague Electric Railway and Motor Company, and the General Electric Co. He has achieved fame as an electrical engineer and as an inventor, and has obtained many patents for inventions in electricity, mechanics, and thermo-dynamics, most

of which have been incidental to his undertakings as an engineer. His most important electric work has been in the development of the general use of alternating current and in the invention and design of machinery to further the practical application of alternating current, while his most important mechanical work has been in connection with the development and introduction of the steam turbine. He designed and directed the development of the Curtis turbine by the General Electric Co., every detail of which was radically new, and which was carried on with a rapidity almost unprecedented in such undertakings. He designed the machinery for the first ships driven by electric motors, and was the first serious promotor of electric ship propulsion, conducting a series of experiments with the United States collier *Jupiter* which are destined to be epoch-making in the history of marine transportation. He is the inventor of several types of transformers, including an air-blast type which has been extensively used; of several types of insulation of alternators, and of other details of the design of alternators which have met with general acceptance. He is the original inventor of the oil switch, a device which is now almost universally used in large electrical work. The varnished cambric cable, which is widely used, is also an Emmet invention. He is the inventor of the vertical shaft steam turbine, of which a very large number have been built, and many details of turbine design in general use are to his credit. Mr. Emmet was responsible for most of the later and most successful and largest electric work of the Niagara Falls Power Co., also for the design and introduction of the Curtis steam turbine for electric uses. His achievements have been as a pioneer of new methods rather than as an inventor, and much of his most original and most useful work could not be effectively patented nor perhaps even classified as invention. Mr. Emmet is the author of "Alternating Current Wiring and Distribution" (1894). He is a member of the American Philosophical Society, American Institute of Electrical Engineers, The American Society of Mechanical Engineers and the Society of Naval Architects and Marine Engineers. He is also a member of the University and Engineers clubs of New York, of the Mohawk Golf, the Lobique, Salmon, Adirondack League, Mohawk and Schenectady Boat Clubs. He received the degree of D.Sc. from Union College in 1910.

SPENCER MILLER

Spencer Miller, the other appointee of the Society, was born at Waukegan, Ill., April 25, 1859, son of Samuel Fisher and Charlotte (Howe) Miller, of Worcester, Mass. He was graduated at the Worcester Polytechnic Institute in 1879, and after tutoring for a few months at Amherst College, entered the shops of the U. S. Wind Engine & Pump Co. of Batavia, Ill., where he remained for nearly a year. He then became

a draftsman with the Link-Belt Machinery Co., Chicago, where he designed a number of rope drives, and a novel equipment for handling cargo by continuous systems of conveying for the Union Steamboat Company.

He made important improvements in rope driving with grooved pulleys of different diameters by varying the angle of the grooves. This invention was the subject of a paper entitled: "A Problem in Continuous Rope Driving," presented by him before the American Society of Civil Engineers in 1897. In 1886 he became associated with the Lidgerwood Manufacturing Co. of New York, which was then manufacturing a crude overhead cable system involving fall-rope carriers of the chain connected type, and he developed an entirely new fall-rope carrier system, the important part of the Lidgerwood cable-way of commerce. It was immediately adopted in various parts of the world for use in the construction of government fortifications, dams, filtration beds, sewers and similar work as in open mining. One of the stubborn engineering problems solved by Mr. Miller was the removal of cypress logs from Louisiana swamps, by means of a log-skidding cableway that reduced the cost of logs at the mill more than 50 per cent, and increased the capacity of the saw mills 400 per cent. One of the early problems of the Spanish-American war was presented to the Navy Department in the question of coaling ships at sea, and he designed a marine cableway that made it possible to tranship coal under headway at sea. In coaling ships in harbor his method of broadside handling has increased the capacity from 25 to 150 tons per hour, and one man now does the work which under the old system required eighty. Many new colliers of the U. S. Navy, notably the *Jason*, *Orion* and *Neptune*, are equipped with this transfer system, for delivering coal to ships alongside in smooth water. In 1914 he made the refueling of warships at sea the subject of a paper read before the Society of Naval Architects and Marine Engineers. One of the most revolutionary devices invented by Mr. Miller is his breeches buoy cableway apparatus in use by the U. S. revenue cutter service, by which passengers can be rescued from any ship in the heaviest sea.

Aside from his engineering activities, Mr. Miller is greatly interested in civic and municipal improvement, especially in the establishment of public libraries, parks and playgrounds in his home city, South Orange, N. J. He is a director of the South Orange Free Public Library and past president of the Playground Commission of South Orange. He is vice-president of the Essex County Mosquito Extermination Commission of New Jersey, and is the author of a paper entitled "Prevention of Mosquito Breeding," read before the American Society of Civil Engineers in 1912. He is a manager of The American Society of Mechanical Engineers; member of the American Society of Civil En-

gineers, American Institute of Mining Engineers, Society of Naval Architects and Marine Engineers, and the Canadian Institute of Mining Engineers. He is also a member of the Engineers Club, New York; Essex County Country Club, Orange, and the Metropolitan Club and University Club of Washington.

The representatives chosen from the other societies are as follows:

Aeronautical Society of America: Matthew Bacon Sellers of Baltimore, Md., and Hudson Maxim of Brooklyn, N. Y. Mr. Sellers is a graduate of the Lawrence Scientific School and is at present director of the Technical Board of the Aeronautical Society of America. He was the first to determine dynamic wind pressure on arched surfaces by means of "wind funnel." Mr. Maxim is an ordnance and explosive expert and maker of the first smokeless powder adopted by the United States Government.

American Chemical Society: W. R. Whitney of Schenectady, N. Y., and L. H. Baekeland of Yonkers, N. Y. Mr. Whitney is a graduate of Massachusetts Institute of Technology, '90. He is at present director of the Research Laboratory of the General Electric Company where he has been the moving spirit in the perfection of metallic electric lamp filaments and the development of wrought tungsten. Mr. Baekeland is a graduate of the University of Ghent, '82. He was the founder of the Nepera Chemical Company and inventor of photographic paper and bakelite. He is at present in private practice.

American Electrochemical Society: Joseph Williams Richards, of South Bethlehem, Pa., and Lawrence Addicks of Chrome, N. J. Mr. Richards is professor of electro chemistry at Lehigh University and is the author of numerous works on electro metallurgy. Mr. Addicks is a graduate of the Massachusetts Institute of Technology, '89, and a member of the Am. Soc. M. E. At the present time, he is consulting engineer for Phelps, Dodge & Co. and is an authority on the metallurgy of copper.

American Institute of Electrical Engineers: Frank J. Sprague of New York City and B. G. Lamme of Pittsburgh, Pa. Mr. Sprague is a graduate of the Naval Academy, '88, and now is consulting engineer for the Sprague, Otis and General Electric Companies. He was the founder of the Sprague Electric Railway Motor Company and was concerned in establishing the first electric trolley systems in the United States. Mr. Lamme is a graduate of the Ohio State University, '88, and is now chief engineer of the Westinghouse Electric and Manufacturing Company and a prolific inventor.

American Institute of Mining Engineers: William L. Saunders and Benjamin B. Thayer of New York City. Mr. Saunders is a graduate of the University of Pennsylvania, '86, and a member of the Am. Soc. M. E. He is chairman of the board of directors of the Ingersoll-

Rand Company and inventor of many devices for subaqueous and rock drilling. Mr. Thayer is a graduate of Harvard University, '85. He is president of the Anaconda Copper Mining Company and an authority on explosives.

American Mathematical Society: Robert S. Woodward of Washington, D. C., and Arthur G. Webster of Worcester, Mass. Mr. Woodward is a graduate of the University of Michigan, '72. He is the president of the Carnegie Institution and an authority on astronomy, geography and mathematical physics. Mr. Webster is a graduate of Harvard, '85, and is a professor at Clark University. He is an authority on sound, its production and measurement.

American Society of Aeronautic Engineers: Henry A. Wise Wood and Elmer A. Sperry of New York City. Mr. Wood is engineer and manufacturer of printing machinery and student of aeronautics. Mr. Sperry is a graduate of Cornell, '76, and Mem. Am. Soc. M. E. He is the founder of the Sperry Electric Company and designer of electric appliances and gyroscopic stabilizer for ships and aeroplanes and the gyrocompass.

American Society of Civil Engineers: A. M. Hunt and Alfred Craven, both of New York City. Mr. Hunt is a graduate of the Naval Academy, '79, and a Mem. Am. Soc. M. E. He is a consulting engineer experienced in the development of hydroelectric, steam and gas plants. Mr. Craven is also a graduate of the Naval Academy, '67. He is chief engineer of the Public Service Commission and was formerly Division Engineer in charge of the construction work on the Croton Aqueduct and reservoirs.

Inventors' Guild: Peter C. Hewitt of New York City and Thomas Robins of Stamford, Conn. Mr. Hewitt is an inventor of electric lamp appliances to enable direct current apparatus to be used with alternating current circuits, and devices for telephones and aircraft. Mr. Robins is a graduate of Princeton. He is now president of the Robins Conveying Belt Company and inventor of many devices for conveying coal and ore.

Society of Automobile Engineers: Andrew L. Riker of Detroit, Mich., and Howard E. Coffin of Detroit, Mich. Both Mr. Coffin and Mr. Riker are members of the Society and past presidents of the Society of Automobile Engineers. Mr. Coffin is a graduate of the University of Michigan, '96. He is now vice-president of the Hudson Motor Car Company and active in the development of internal combustion engines. Mr. Riker is vice-president of the Locomobile Company. He is an electrical and mechanical engineer and inventor of many automobile devices.

YALE ENGINEERING ASSOCIATION

An organization has recently been formed among graduates from Yale University, to be known as Yale Engineering Association. Its purpose is to serve in an advisory capacity the engineering departments

of the University, to make recommendations regarding the courses, to furnish speakers on engineering topics for the undergraduates, to help young graduates in securing positions, to attack the problem of engineering education and to encourage Yale men to become affiliated with national societies. The executive committee has Edwin M. Herr, Mem. Am. Soc. M. E., as President, Harry N. Covell, Mem. Am. Soc. M. E., as Vice-President, and Richard T. Dana as Secretary-Treasurer. The first meeting of the association will be held in New Haven in the early part of November.

REPORT ON THE RESERVE CORPS OF CIVILIAN ENGINEERS

The suggestion was made last spring that the national engineering societies offer to assist the U. S. War Department in the formation of an engineer reserve in the United States Army. When brought to the attention of some of the officers of the Army, the suggestion was commended and they confirmed the belief that the need of such a reserve was a real one. The European War has distinctly shown that in time of war engineers of varied experience are required on a scale never before realized. In our own army no adequate provision is made for great numbers of engineers, for although the regular corps of engineers is composed of men of the very highest professional proficiency in certain lines, it is far short of the numerical strength that would be immediately required.

Acting on the suggestion for an engineer reserve, the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Institute of Consulting Engineers appointed committees authorized and directed to take such steps as might be advisable to urge the organization of such a reserve corps as part of the regular army, and so assist in putting the United States in a better condition of preparedness against war. Conferences were held with the Secretary of War and the officers of the General Staff and of the War College, and so much encouragement was received that it was felt advisable to form a single committee to represent jointly the five societies—in short, the engineering profession as a whole. This will simplify future conferences with those in authority and show that the various engineering organizations are earnestly coöperating.

After obtaining formal permission from the five societies, a joint committee has now been formed, consisting of the chairmen of the previously appointed society committees, as follows:

Wm. Barclay Parsons, *chairman Committee, American Society of Civil Engineers,*
Henry S. Drinker, *chairman Committee, American Institute of Mining Engineers,*

William H. Wiley, *chairman Committee, American Society of Mechanical Engineers,*
Bion J. Arnold, *chairman Committee, American Institute of Electrical Engineers,*
Ralph D. Mershon, *chairman Committee, American Institute of Consulting Engineers.*

This committee has selected Mr. Parsons as chairman and is in communication with the War Department.

Before a reserve corps can be formed, legislation authorizing it must be passed by Congress and approved by the President. The details of such legislation are now being studied by the War Department. While no decision has been reached, it is under consideration to issue commissions as officers to such engineers as will meet certain professional and physical standards. These officers would, in times of necessity, be subject to orders from the Secretary of War as officers of the army, and at other times they would perform such duty as would not seriously interfere with their ordinary work, but would give each officer some military education and experience. In this way it is hoped to have a large body of engineers which could be called quickly to duty.

The separate committees are still in existence to do the necessary work among their fellow members of the several societies as soon as the decision of the War Department is given and a general scheme of organization is adopted.

WM. BARCLAY PARSONS, *Chairman,*
HENRY S. DRINKER,
WILLIAM H. WILEY,
BION J. ARNOLD,
RALPH D. MERSHON.

Joint Committee of the National Engineering Societies on the National Reserve Corps of Engineers.

August 28, 1915.

INTERNATIONAL GAS CONGRESS

The International Gas Congress, under the auspices of the American Gas Institute, was held in San Francisco during the week of September 27th. The Congress opened with the annual meeting of the Pacific Coast Gas Association and a reception to the President of the American Gas Institute, Dr. Alex C. Humphreys, Mem. Am. Soc. M. E. The following day the professional sessions of the Congress were commenced and the annual meeting of the American Gas Institute took place. Symposiums on illumination, commercial aspects of the gas business and modern coal gas processes and of present British practices in the manufacture of coal gas were held during the week. President C. C. Moore of the Panama-Pacific International Exposition presented the Congress with a bronze medal. A number of entertainment features were provided and a visit was paid to the gas exhibits at the Exposition. The Congress closes on October 2.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON NOVEMBER 10, 1915

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their ages would qualify them and not with regard to professional qualifications, i. e., the ages of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior Grade only. Applications for change of grading are also posted.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

ALEXANDER, JOHN S., Dist. Mgr., Diamond Pwr. Specialty Co., Philadelphia, Pa.
 ANDERSON, ANDREW F., Instructor in Shopwork, Schools of the City of New York.
 BEAGHEN, THOMAS, JR., Master Car Builder, Union Tank Line Co., New York.
 BIGGETT, FLORENCE C., JR., Ch. Engr., United Engrg. & Fdy. Co., Pittsburgh, Pa.
 BRIDGES, LUTHER W., Mech. Engr., with Chas. H. Tenney & Co., Boston, Mass.
 BUERGER, CHARLES B., Cons. Engr., Atlantic Refining Co., Philadelphia, Pa.
 CANDA, CHARLES A., Secy., Chrome Steel Wks., Chrome, N. J.
 CHATILLON, RALPH F., Vice-Pres., John Chatillon & Sons, New York.
 CLARK, ALBERT B., Efficiency Engr., Commonwealth Edison Co., Chicago, Ill.
 DAWSON, GEORGE H., Engr.-in-charge of Equip., Remington Arms & Ammunition Co., Ilion, N. Y.
 DISSEL, THEODORE A., Mgr., Cameron Appliance Co., Everett, Mass.
 EDMONDSON, RALPH S., Engr., Amer. Abrasive Metals Co., New York.
 ERLIN, WILLIAM C. L., 2nd Vice-Pres. and Ch. Engr., The Philadelphia Elec. Co., Philadelphia, Pa.
 ENKE, GEORGE P., Insurance Engr., Goffe & Little, New York.
 FEELEY, FRANK G., Mgr., Chicago Branch, M. D. Knowlton Co., Chicago, Ill.
 FELL, HUGH P., Mech. Div. Ch., Elec. Bond & Share Co., New York.
 FENN, ROBERT H., Engr. and Pur. Agt., Kent Mill Co., Brooklyn, N. Y.
 FERGUSON, HUGH M., Mech. Engr., Missoula Light & Water Co., Missoula, Mont.
 FRALICH, JOHN S. Y., Asst. Res. Engr., The Westinghouse Air Brake Co., Chicago, Ill.
 GALE, WALTER L., Engr. and Tool Designer, Hopkins & Allen Arms Co., Norwich, Conn.
 GENTLES, FRANK, formerly Ch. Engr., Cathedral Corp., Garden City, L. I., N. Y.
 GILLIAM, THOMAS B., Engr. of Tests, Island Creek Coal Sales Co., Cincinnati, Ohio.
 HATFIELD, ROBERT L., Prop., Hatfield & Co., Newark, N. J.

The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into the Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential, and is solely for the good of the Society, which it is the duty of every member to promote. These candidates will be balloted upon by the Council unless objection is received by November 10, 1915.

SAN FRANCISCO MEETING

THE Panama-Pacific International Exposition, held this year at San Francisco, and the notable engineering event exemplified in the International Engineering Congress, were the occasion of the special meeting of the Society on September 16 and 17, which is the first mid-year meeting held by the Society since the early years of its organization. Advantage was taken of this unusual opportunity to deal with subjects of local interest. Two of the papers were devoted to engineering at the Exposition and two others to the oil engine in relation to power production on the Pacific slope. A fifth paper dealt with an investigation upon the Strength of Gear Teeth made at Leland Stanford Junior University, California. The two papers upon the Exposition are published in this issue practically in full, while the remaining three will be given in the next number of *The Journal*.

ENGINEERING FEATURES OF THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION

BY GUY L. BAYLEY, SAN FRANCISCO, CAL.

Member of the Society

An exposition is a modern city built to order and as such must be provided with every utility and convenience with which the public is familiar. Even though the existence of the exposition be short, none of these may be omitted or restricted. In the planning and construction of such a project all branches of engineering play a part and, while there are many details which require special treatment, the real engineering problem lies in the modifying of standard practice to secure the temporary service desired at the lowest possible cost, with the use of such material as will facilitate the final dismantling of the exposition and the realization of a high salvage value.

HYDRAULIC FILLS

At the time the Exposition took possession of its site, that portion of the grounds to be occupied by the main buildings (about 70 acres) was under 12 ft. of water at mean high tide, and it was necessary to fill this section and, in addition, the low lands within the Presidio (a U. S. Military reservation). The filling was done by suction dredges which operated off-shore a distance of about 300 ft. in depths of from 30 to 50 ft. The discharge carried 8 per cent to 10 per cent of solid matter which ran 60 per cent to 70 per cent sand, the balance being sea mud and silt. The dredged material was handled so that it displaced about 5 ft. of soft ooze which existed in the bottom of the basin, the ooze being

dissolved and carried out through the waste gates. In order to expedite the work of removing the soft portions of the original bottom, water instead of a mixture was pumped at intervals. To reclaim this portion of the site required the pumping of 1,300,000 cu. yd. of material at a cost of \$218,000.

Shortly after the fill had been completed, settlement stakes were driven and readings taken to establish the rate of settlement, which was rapid at the start and decreased shortly to a slow but uniform rate. After the initial settlement had taken place borings were made at the sites of all buildings of the main group to determine the character of the underlying material and depth of hardpan. Test piles were driven to ascertain the supporting value of the ground at various depths. These tests showed that the dredger fill not only had no supporting value, but actually produced a load on the piles driven through it, tending to drag the piles down at the speed of its own settlement. As the result of a large number of tests, it was decided not to depend upon the thin strata of blue mud and clay underlying the dredger fill, but to drive the piles to a penetration of 1 in. to the blow of a No. 1 Vulcan steam hammer in the hard layer of green sand and clay overlying the hardpan.

In the areas not affected by the dredger fill, there was a layer of overlying soft clay, and tests showed that short piles terminating in the sand offered practically as much resistance as those driven through the sand into the clay. The sand had a supporting value of 3000 lb. per sq. ft. and spread footings were considered, but it was found that short piles averaging 14 ft. provided a cheaper and simpler construction. It was also thought that the adoption of pile footings would offer greater resistance in case of earthquake, previous experience having indicated that structures were most affected when resting on filled ground by means of spread footings.

The decision not to drive into the substratum of soft clay resulted in a great saving. The results of these tests were of

The organization of the engineering departments of the Panama-Pacific International Exposition, the layout of the grounds, the design and construction of the buildings, and the operation of the service facilities have proven an engineering undertaking of the greatest magnitude. Mr. Bayley has pointed out in his paper many unusual features of the great undertaking which will be of absorbing interest to engineers. Attention is called to the extensive use of timber construction for the buildings, which introduced unusual constructive problems. The provisions for power, water supply, fire protection, sanitation, etc., are discussed in considerable detail, and further information upon these important features is to be filed by the author in the Library of the United Engineering Society for permanent reference.

Presented at the Panama-Pacific International Exposition Meeting of the Society, San Francisco, September 1915. The paper may be obtained in pamphlet form; 25 cents to members, 50 cents to non-members.

the greatest value as they provided definite data for the design of foundations. The information gained was furnished to bidders and naturally resulted in lower prices, as contractors were able to know the lengths of piling required and thus avoid unnecessary waste. The total number of piles driven was 15,654 and the linear feet 645,692. The average cost was $24\frac{1}{2}$ cents per lin. ft. below cut-off, and the average length of pile 41.2 ft.

The dredger fill in the Presidio was shallow, not exceeding 6 ft. at any point. The total amount pumped was 400,000 cu. yd. which reclaimed 114 acres of land at a cost of \$84,000. The buildings in this area are light frame structures and as a rule rest on spread footings.

STRUCTURAL DESIGN

With the exception of the frames of the Tower of Jewels and the Palace of Fine Arts and the dome of the Palace of

From an engineering viewpoint, the Tower of Jewels is probably the most interesting structure on the grounds. It is 435 ft. high and 120 ft. square in plan from the ground level to elevation 152 ft., from which level to elevation 335 ft. it takes the form of a truncated pyramid. From elevation 335 ft. to 364 ft., the frame is made up of four vertical columns 20 ft. apart and braced with rods. Above this elevation the frame forms a tower 8 ft. by 8 ft. in plan to elevation 397 ft., from which point runs a central post which supports a ball 17 ft. in diameter. The framing of the tower required 1403 tons of structural steel.

The glass dome of the Palace of Horticulture has an extreme height of 185 ft., and is 152 ft. in diameter. The upper portion has the form of a half sphere, while the lower portion is cylindrical. The supporting frame of the dome was figured as a true dome and consists of 24 steel ribs tied together by 11 horizontal rings. The dome and cylinder are

FIG. 1 PANAMA-PACIFIC INTERNATIONAL EXPOSITION, 1915

Horticulture, the buildings are timber structures. All the buildings, except Festival Hall, have pile foundations for the framework. The floor sub-structures of those buildings located on the dredger fill have pile foundations and the others spread footings or mud sills, depending upon the nature of the ground. The pile foundations for the Tower of Jewels are capped with reinforced concrete. Prior to the decision on the type of foundations to be used in each instance, tests were made of the ground on which the buildings were to be erected. These tests gave accurate data as to the length of piles required and the allowable loading. The piles varied from 13 to 75 ft. in length, although a few 120 ft. long were required under the Transportation Building. The safe carrying capacity of one pile was found to be 20 tons.

carried on plate girders and trusses which in turn are supported by 8 structural piers 65 ft. in height.

The framing of the dome of Festival Hall presented many difficulties, owing to the size of the dome and the large arched openings on two sides. The curved dome was built on a supporting pyramidal dome 140 ft. in diameter with 16 trussed ribs. This dome was carried by 4 main piers and by 8 columns. The ribs occurring over the arched openings were carried by two trusses of 77-ft. span. The pyramidal dome was designed as a true dome, the ring tension at the supports being cared for by two $3\frac{1}{4}$ -in. rods. The dome roof with a diameter of 172 ft. was built of sheathing supported by 2-in. by 6-in. rafters resting on studded walls which were carried by beams spanning the main ribs. The exterior coiling was suspended from the dome ribs.

FIG. 2 STEEL FRAME OF TOWER OF JEWELS TO ELEVATION 152 FT.

FIG. 3 COMPLETED STEEL FRAME, TOWER OF JEWELS

FIG. 4 TIMBER FRAME OVER STEEL FRAME, TOWER OF JEWELS

FIG. 5 TOWER OF JEWELS, PLASTER WORK BEING APPLIED

For a frame structure the Palace of Machinery claims attention on account of its size—968 ft. by 368 ft., with a height of 136 ft. in the transverse bays and 120 ft. in the longitudinal bays. The spans of the longitudinal and transverse bays are 75 ft. The arched trusses give the building an attractive appearance and the framing is of interest, particularly at the intersections of the longitudinal and transverse bays. The columns of the longitudinal bays were designed to support traveling cranes carrying loads up to 30 tons.

Owing to fire protection requirements, the frame of the Palace of Fine Arts was built of steel. The building is curved in plan, 950 ft. long and 135 ft. wide. Three hinged arches were used for this building, the span being 131 ft. and the height from the floor to the center hinge 48 ft. Steel channels placed beneath the floor served as ties for the lower hinges. Light bracing trusses were used to connect the arches and form supports for the purlins. The roof and walls were constructed with cement-plaster on metal fabric, the roof with a thickness of 3 in. and the walls 2½ in.

The Auditorium, located in the Civic Center, was built at an expense of over \$1,000,000, and is a permanent fireproof structure of four stories, occupying a city block 200 ft. by 187 ft. The main hall has a seating capacity of 10,650, and there are 10 halls or large rooms for conventions. Flanking the main hall on each side and extending the height of two stories are banquet rooms, 56 ft. by 136 ft. The only feature of the building that is unusual is the dome, which may be described as a truncated octagonal pyramid with a maximum diameter of 205 ft. 6 in. and a height of 40 ft. The height of the spring line of the dome from the floor is 79 ft. The dome framework is of interest, not only on account of its great diameter, but also from the fact that it was designed as a true dome. The eight main trussed-ribs are 6 ft. deep at the upper end and 10 ft. at the lower, and are carried by eight columns. The horizontal thrust at the bottom is taken up by four 17½-in. by 6-in. eyebars. The supporting columns are connected by trusses having a depth of 14 ft.

There are no unusual features in the structural design of the eight buildings which form the main group, although the framing of the domes and half domes were interesting problems on account of the use of timber where steel would have been used in ordinary practice. The domes are 100 ft. in diameter and 162 ft. high, each with 32 ribs resting on a circular girder which in turn is supported by four girders with connecting diagonals at the corners, thus providing eight points of support for the ring. Half domes, 112 ft. high and 72 ft. wide, form the entrances to the Palaces of Food Products and Education and are constructed of double, 3-hinged timber arches for carrying the walls and arched roof, and a steel 3-hinged arch for carrying the trussed ribs. The construction of the walls is quite different from that employed at previous expositions in that a single line of 2-in. by 6-in. studs, 18-in. centers, are used with horizontal girders every 13 ft., instead of the usual double line of studs laced together. The floors in these buildings, as elsewhere, are constructed of 2-in. shiplap. Where spread footings were used, the floor was laid on 2-in. by 8-in. joists, 2-ft. centers with 9-ft. spans, supported by 6-in. by 8-in. girders with 9-ft. spans, while with pile footings 2-in. by 12-in. joists are used 2-ft. centers, 14-ft. spans, with 10-in. by 16-in. girders, 20-ft. spans.

The brevity with which this phase of the work has been treated is no index to its importance, as the making of the structural designs formed a large part of the engineering work. Necessarily, once the elements of a design had been worked out, there was much duplication, but a great deal of skill and originality were shown in applying to timber framing much of the knowledge which has been acquired in recent years relative to steel frame structures.

At the start rules were made governing all structural work in which the allowable loads, stresses and other designing data were established, with the result that the designs were consistent throughout. Some idea of the volume of work handled by the structural bureau may be gained from the number of drawings made, there being 781 sheets covering an area of 13,277 sq. ft., from which 27,355 prints were made. When the work was at its height 70 structural draftsmen were employed by the structural bureau.

SEWER SYSTEM

Use was made of a number of city sewers which crossed the site, one of which was large enough to be used as the main outfall for all sanitary sewage. A separate system was installed for storm water, with frequent connections to the Bay. The plan of using separate sewers was adopted as it was permissible to place the storm sewer near the surface and use a cheap form of construction. The amount of storm water to be cared for was figured from the San Francisco rainfall rate curve, which gives a rate of 2.16 in. per hour for a 5-min. interval and a rate of 0.598 in. for a 60-min. interval. The handling of the sanitary sewage in the low area within the Presidio necessitated a pumping plant, which was located near the center of the district and discharged into the main outfall through 1170 ft. of 20-in. wood stave pipe.

The sewer system was simple and direct and was based on the use of second quality vitrified pipe in sizes from 8-in. to 15-in. and banded wood stave pipe for sizes up to 30-in., except that in the States and Foreign sites, where water-tightness was a requirement, wood stave pipe as small as 10-in. was used. The sewer system, including catch basins, cost \$142,000, and comprised some 28 miles of pipe.

TRANSPORTATION

The handling of building material and exhibits proved to be one of the largest tasks in the construction of the Exposition.

Owing to the location of the Exposition along the shore of the Bay of San Francisco, it was possible to unload the lumber, which formed the bulk of the material to be handled, direct from vessels to the Exposition's wharves. The principal problem was to get the lumber away from the wharves which provided little or no storage, and the plan adopted was to use 2-wheeled lumber trucks, upon which the lumber was landed by ship's tackle. Single horses were used to drag the trucks, the driver guiding the truck by hand.

The unloading rate per vessel reached 30,000 ft. per hour at times, and to care for this quantity of lumber required some 200 trucks, 68 horses and 140 men.

Plank roads were laid around the four sides of each building site and over these the lumber was hauled to the adjacent storage space. The lumber was so ordered that an entire cargo would be for one designated building, and there was, therefore, no necessity for sorting on the wharf. The work of receiving, hauling and rough-piling the lumber was let to

FIG. 7 DOME OF AUTORIUM

FIG. 6 FESTIVAL HALL PARTIALLY COMPLETED

FIG. 9 COMPLETED DOME OF PALACE OF HORTICULTURE

FIG. 8 DOME AND ARCHED OPENING, FESTIVAL HALL

contract at prices varying from 35 cents per 1000 ft. for short hauls to \$1.10 per 1000 ft. for long hauls. The total amount of lumber handled under contract was 68,131,000 ft. and the amount paid to the contractor for this work was \$68,000. The plank roads referred to consisted of 3-in. planks 16 ft. long laid on 3-in. sills, and were laid by the Exposition's forces, approximately 1,950,000 ft. of lumber being used for this purpose alone.

In addition to the amount of lumber unloaded by contract there was handled over the wharves, in the manner described, about 9,500,000 ft. of lumber. The balance of the lumber used by the Exposition and its participants was purchased locally and delivered by teams and wagons, and amounted to about 32,000,000 ft.

Building materials other than lumber have been estimated as being about 800,000 tons. To handle these enormous quantities of materials expeditiously and without confusion required careful planning of temporary roadways and the systematic routing of traffic.

FIG. 10 CONNECTION OF PILES TO GIRDERS, PALACE OF HORTICULTURE DOME

The Exposition Terminal Railway was built primarily for handling exhibits, but was used to advantage during the construction period for distributing 36,000 tons of construction material and 5,000 tons of general freight received on cars. This road was built by the Exposition's forces and included 11½ miles of standard track, 3½ miles of which was laid within the exhibit buildings for unloading direct from the cars to the exhibitors' spaces. A spur track was run to the U. S. Transport Dock so that freight from ocean-going vessels could be loaded on the Exposition's cars. Cars from the various transcontinental lines were brought to the grounds on barges, for the accommodation of which the Exposition built a freight slip.

The design of this ship follows the standard practice of the San Francisco Bay district in that the bridge forms a span between the boat and the shore. The bridge is hinged on the shore end, while the outboard end is suspended by

cables which pass over sheaves to suitable counterweights. The counterweights are sufficient to overbalance the weight of the bridge and eliminate danger of dropping the bridge into the bay. To lower the bridge that portion of the counterweights required for overbalancing is raised by hydraulic means and the bridge is allowed to land on the shelf or recess provided in the bow of the barge. In operation, the live load on the bridge is divided between the boat and the shore supports, and the galleys frame carries only the weight of the bridge and counterweights—about 400,000 lb.

FIG. 11 STEEL DOME OF PALACE OF HORTICULTURE

The hydraulic equipment consists of a vertical cylinder 28 in. in diameter and 12 ft. long, a motor-driven triplex pump and an accumulator. Cables run from the crosshead on the piston rod to the two auxiliary counterweights which rest on the main counterweights when the bridge is in the raised position. The water supply to the cylinder is controlled by a piston type valve fitted with cup leathers. This valve is operated by hand, but in case of overtravel of the bridge is automatically closed. The accumulator controls the motor operating the pump so as to maintain a constant pressure of 90 lb. per sq. in.

A 20-ton locomotive crane with a 35-ft. boom and grab bucket was secured at an early date, and, in addition to its use for unloading road material from cars, spotting cars and similar work, was found most useful for unloading heavy boxed trees and the erection of standards and statuary, an extension boom being used in many instances.

The work of the electrical department was expedited by the use of a 1-ton storage battery crane truck having a 2-ton trailer. While adapted for general delivery work, the greatest value of this was realized in transporting transformers and oil drums from the warehouse to the numerous building vaults. The transformers were loaded on to the trailer and hauled to a point opposite the vault, where they were lifted off the trailer one at a time and landed on dolly trucks. Planks were laid from the curb up the steep terraces and into the vaults, over which the dolly trucks were hauled by a

rope running around a block inside the vault and fastened to the back of the truck. Transformers up to 50 kw. in size were handled in this fashion with surprising ease and speed. After building an extension to the boom, the crane was used for setting gas and incandescent standards. No other type of equipment proved as useful as the battery truck crane for handling loads not exceeding one ton.

As the Exposition had undertaken to deliver all exhibits from the cars to the designated space, and as it was known from past experience that most of the exhibits would arrive in the 60-day period prior to the opening, this problem called for careful consideration. Transveyors consisting of 4-wheeled hand trucks for use in connection with special detached platforms were adopted for this service. The freight was loaded on the platforms which were later picked up by the transveyors and transported to the exhibit space.

Storage battery industrial trucks were also used for handling exhibits, a type being adopted which had an extension platform suitable for handling bulky goods. These trucks had a capacity of 2 tons each and frequently towed several transveyors in addition to carrying a full load. Motor cars and trucks have played no small part in the construction of the Exposition, in that they have enabled men and materials to be moved rapidly when and where required. With work scattered over a territory a square mile in area and over two miles in length, many cases arose where slower methods of transportation would have proven costly and delayed the completion of the work on time.

The Exposition required for the use of its construction departments 20 Ford automobiles and 14 trucks, of which two were 5-ton, three 2-ton, two 1½-ton, four 1500-lb. and three 800-lb. Just prior to and some time following the opening day this equipment was operated 24 hr. per day, and additional equipment was rented to meet the unusual situation at that time. While the construction program had been practically completed prior to opening day, there was an enormous amount of work incident to getting exhibits installed and cleaning up the grounds. It is estimated that within the last twenty-six hours something like 10,000 tons of debris of various kinds was hauled to the dump and burned.

The transportation of visitors within the grounds was solved to the apparent satisfaction of the public by the use of the auto train consisting of a small tractor and several trailers. The cars of the auto train are low enough to permit passengers to step directly on to the platform and the routes are such that the trains pass within 100 ft. of all buildings. The seats run the whole length of the cars, which have an aisle in the center for the conductor. Each car accommodates 20 passengers, and the gasoline tractor, which is equipped with a Ford engine, is capable of hauling three cars.

FIRE PROTECTION

Certainly no exposition had a fire protection system comparable with the one installed at this one, and it may safely be said that few communities enjoy an equal security against fire. Located as it is within the city proper and close to the residential district, the Exposition represents a tremendous fire hazard to the city, and the problem of fire protection was carefully studied by the engineers of the Exposition in consultation with the Board of Fire Underwriters. In compliance with the general plan adopted, a high pressure water

system was installed throughout the main portion of the grounds and as far west as the Live Stock section.

The system was designed to operate as a part of the city's auxiliary water supply system and to be capable of delivering 15,000 gal. per min. at any hydrant, at a pressure of 200 lb. per sq. in. The distribution system includes 52,000 lin. ft. of pipe in sizes from 6-in. to 16-in. lap welded pipe and Dresser all-steel couplings are used throughout, with extra heavy flanged cast-iron fittings and valves. All hydrants are of the flush type, set in circular concrete manholes with wooden covers. The hydrants have two 3-in. outlets and are spaced approximately 300 ft. apart. With the exception of the Fine Arts and Horticulture buildings, the high pressure system is brought into all exhibit buildings. Four 8-in. pipes are run into each building, one from each side, and serve the inside and roof hydrants, the automatic sprinkler system, the cornice sprinklers and the roof monitors.

The 8-in. valves controlling the supply to the buildings are kept closed, but the 4-in. by-pass valves are left open. This practice was adopted to limit the damage in case of a break inside the building. These 8-in. control valves are located outside the buildings, and in the same manholes are installed 6-in. cross connections to the low pressure supply, with check and gate valves, so that in the event of a failure in the high pressure supply the sprinklers will be fed from the low pressure system. The roof and inside hydrants have 3-in. outlets, and are so located that any portion of the roof or floor can be reached with 150 ft. of hose. The monitors have a capacity of 1500 gal. per min., and are set so as to play on the buildings opposite them as well as on the roofs on which they are located. The cornice sprinklers are arranged to produce a water curtain on the sides of the buildings which face one another and are less than 150 ft. apart.

Automatic sprinklers are installed in all exhibit buildings, with the exception of the Palaces of Machinery, Horticulture, Fine Arts, the Festival Hall and the administration portion of the California building. The domes in the eight buildings of the main group and the ceiling of the Palace of Machinery are not equipped with sprinklers, as the height is so great that the effectiveness of sprinklers is questionable.

In the design and construction of the buildings fire protection was borne in mind. Concealed spaces where a fire might flourish unobserved were carefully avoided, and heat curtains were used extensively to prevent circulation of air and insure the confinement of heat and operation of the automatic sprinkler and fire alarm systems. Reinforced concrete firewalls were built where the architectural requirements resulted in buildings being connected by colonnades or other decorative features. The exterior building walls were carried down to the ground surface and sheathed on the inside to a height of 12 ft. above the floor. The roofing used had a top sheet of either crushed brick or asbestos, and wire glass was used in all skylights, preventing fire being caused by anything falling on roofs.

Additional protection was afforded by hydrants connected to the domestic water supply system by the installation of 3-gal. chemical fire extinguishers and by suction pipes at the various parts to be used in connection with fire engines.

The fire department is operated as a part of the city's department, which answers all alarm calls on the Exposition grounds. Three fire houses, with equipment, are located on the grounds. A complete fire alarm system was installed

FIG. 12 TYPICAL TIMBER DOME CONSTRUCTION

FIG. 13 FRAMING OF HALF DOME, FOOD PRODUCTS BUILDING

FIG. 14 FRAMEWORK OF FESTIVAL HALL

FIG. 15 FRAMING OF HALF DOME, PALACE OF EDUCATION

and a complete central office located in the Liberal Arts building is operated as an exhibit.

All exhibit buildings and many of the detached buildings, especially those having moving picture apparatus, are equipped with an automatic fire alarm system of the pneumatic tube type. Copper tubing not exceeding 1000 ft. in length is run around the ceilings or parts of buildings where heat from a fire would quickly affect the tubing. The tubing is 0.09-in. outside diameter with a hole approximately 0.045 in. in diameter. One end of each tube is connected to a detector, consisting of a sensitive metallic bellows such as is used in aneroids. In the event of a fire the pressure of the air in the tubing is increased, due to the expansion of the contained air and the bellows expands and closes an electric circuit, which in turn sends a signal to the central fire alarm station and to the annunciators placed at the building entrances to inform the fire department of the location of the fire. The bellows mechanism or detector is located in a steel cabinet which contains five detectors, each connected to about 1000 ft. of tubing. The buildings of the main group have at least five of these cabinets in each building, and some as many as eight, while the buildings of minor importance have a lesser number.

The fire protection measures adopted by the Exposition cost in the neighborhood of \$900,000, but the fire losses up to August 1 have been insignificant and the security obtained has warranted the Exposition carrying only a nominal insurance on completed buildings.

MECHANICAL FEATURES

Power Plant. With three large electric companies in the field, each capable of supplying needs of the Exposition, the necessity for building a power plant was not considered. The Pacific Gas and Electric Company, which furnishes electric energy to the Exposition, has a substation on the grounds, and the interesting feature of a power plant in operation is supplied by the Sierra and San Francisco Power Company, whose 18,000-kw. plant is located within the grounds, about 500 ft. east of the Palace of Machinery. This plant is operated in conjunction with a hydroelectric system for supplying energy to the United Railroads, and is an excellent example of a standby station with steam turbines and oil-fired boilers. Under an arrangement with the Pacific Gas and Electric Company, this steam plant is kept in operation continuously, so that in the event of an interruption in the regular source of supply it will carry the load of the Exposition.

Heating and Ventilating Equipment. With the exception of the spaces occupied as offices, no heating was provided for the main exhibit buildings other than the Service building, Administration building, Press building, Festival Hall, Palace of Horticulture and the Auditorium at the Civic Center.

The heating of Festival Hall is a departure from standard practice in that a system was installed using gas-fired hot-air heaters with forced circulation. While gas at 75 cents per 1000 cu. ft. is an expensive fuel, its use for the short period of the Exposition was justified by the saving in the initial cost of the plant as compared with a steam plant. The heaters and supply fans are located in two rooms, one on each side of the main auditorium. Each fan room contains two steel plate fans, each having a capacity of 1500 cu. ft. per min., and four hot-air furnaces, each capable of burning 440 cu. ft. of gas per hour. The arrangement is

such that one fan serves two heaters and delivers air through registers located in the columns around the main entrance, while the other fan discharges into a plenum chamber beneath the raised side seats, openings being provided in the risers for the discharge of air into the auditorium. Air is removed from the auditorium by two multi-blade exhaust fans installed beneath and on each side of the stage, and having a combined capacity of 5200 cu. ft. per min. All fans are belt-driven by direct current motors equipped with armature control.

In the California building, the administration quarters are heated by 8700 sq. ft. of direct radiation with vacuum returns. Steam for the heating system and for the hot-water supply and kitchen equipment is supplied by two oil-fired, cast-iron boilers operated at a pressure of 5 lb. Ventilation for the ball room is secured by two 60-in. disc fans located in the attic space.

To provide the necessary heat in the dome portion of the Palace of Horticulture, which is essentially a large conservatory, a hot-water system with forced circulation was adopted. The hot water is supplied from a model boiler plant located about 90 ft. south of the main building, in which are installed two oil-fired cast-iron boilers equipped with vertical, rotary burners. Owing to the architectural requirements of the neighborhood, it was undesirable to use a tall stack, and smokeless combustion has been secured with a stack which is only 30 ft. high from the burners and terminates in the staff basket. Forced hot-water circulation is produced by two 4-centrifugal pumps designed to operate against a head of 40 ft., each direct-connected to a 7½-hp. induction motor. Recording thermometers and a flow meter enable accurate records to be kept of the amount of heat delivered by the plant.

The heating required for the section beneath the dome was calculated on the basis of 3,725,000 cu. ft. of space, 54,650 sq. ft. of glass surface, and 15,470 sq. ft. of wall surface. It was assumed that there would be one complete change of air every three hours and a loss of six B.t.u. per hr. per sq. ft. of wall surface and 17 B.t.u. per hr. per sq. ft. of glass surface, making a total of 1,376,500 B.t.u. required per hour to maintain a temperature of 50 deg., with an outside temperature of 35 deg. The four rooms adjoining the dome section were figured for temperatures from 60 to 80 deg. Fahr., which brought the total requirements of the building to 3,582,000 B.t.u. per hr., requiring the circulation of 190,000 lb. of water per hour, with an initial temperature of 250 deg. and a loss of 20 deg. Radiators of the cast-iron type were used instead of the customary pipe coils, with satisfactory results. Thermostatic control was installed in several of the rooms for regulating the temperature of ponds. The plan of using forced circulation and high temperatures made possible a material reduction in the size of the mains and the quantity of radiation required.

Minor heating installations were provided in various buildings, such as the Service building, which is heated by direct steam radiation of the single-pipe system, while the Press building is heated by the Rector system, which burns gas in connection with cast-iron radiator elements, the products of combustion being removed by means of a fan located in the basement. The offices in the Exposition palaces and most of the buildings erected by participants are heated by gas radiators or gas stoves of the radiant type, flues being provided to carry away the products of combustion.

Owing to the fact that the Auditorium in the Civic Center is a permanent, four-story, fireproof building, a modern heating and ventilating system was installed. In order that the main hall might be used for dances and other functions, a system of heating and ventilating was adopted which left the floor free of obstructions. Fresh air is forced through the openings in the balcony risers and grilles along the face of the balcony. The grilles are supplied from separate ducts, whereas the openings in the risers receive their supply from a plenum space beneath the balcony seats. Exhaust fans are provided to remove the air through large grille plates beneath the balcony, along the side walls and through smaller grille plates above the balcony, and just below the base of the auditorium dome.

For supplying fresh air, two fans are installed in the

FIG. 16 INTERIOR OF DOME, MINES BUILDING

basement, each having a capacity of 145,000 cu. ft. per min. Two main exhaust fans, each capable of handling 70,000 cu. ft. per min., are installed in the attic, and two exhaust fans of 75,000 cu. ft. per min. capacity in the basement. Additional supply and exhaust fans are provided for the banquet rooms, toilets and kitchens, these fans having a total rating of 39,000 cu. ft. per min. The fans, of which there are 18, and the vacuum pumps, are belt-driven by motors aggregating some 250 h.p. Heating coils are used in connection with the various fresh air supply fans, and provision has been left for air washers should they ever be found necessary. Direct radiation is used for the upper corridors, convention halls and offices.

Pumping Plants. In addition to the pumping plant de-

scribed under the heading of Water Supply, numerous pumping equipments were installed throughout the grounds in connection with the fountains, the pools, the drainage beneath the buildings, the handling of sewage and the supply of salt water. Belt-driven centrifugal pumps were adopted as a standard, as they permitted the use of rented motors, were lower in first cost, and carry a higher salvage than direct-connected pumps. Another reason for the adoption of the belt drive was the ease with which the pump speeds could be changed to meet conditions of operation different from those planned.

The pumping equipment of a fountain is a simple problem compared with that of laying out the distribution piping and deciding on the form, size and adjustment of the nozzles. It was found that the use of lead pipe for connection to nozzles expedited the work of adjustment, and in many cases the nozzles themselves were formed from lead pipe. Experience indicates that valves or cocks should not be placed close to nozzles as they disturb the flow of water and prevent the realization of a smooth and solid stream. Where groups or decorations are liable to be constantly wet, they should be made of cement, as staff will fail, even though the water may not play directly on it. If canvas is used for lining basins or pools it should be painted on both sides and thoroughly protected against damage from workmen's shoes. Sixteen motors, aggregating 755 h.p., are used for driving pumps to produce water effects.

Transfer Table. The arrangement of the Palace of Transportation necessitated bringing all rolling stock into the building on one track and distributing this equipment to 14 exhibit tracks by means of a transfer table. This transfer table had to be designed to carry the largest locomotives and cars of which, up to that time, there was any record. A standard steel transfer table would have cost from fifteen to twenty thousand dollars, and its salvage value would have been problematical. The transfer table as built cost \$7000, exclusive of foundation. Its deck is 76 ft. long, and it is made up of timber stringers on which are laid the ties and track. This deck is supported on 14 trucks, two trucks to a track. Each pair of trucks is tied together with stringers which carry the deck and transmit the load to the trucks through special steel bolsters. No springs are used and, barring the flexibility due to the timber work, the table is a rigid structure.

The transfer table has a 300 ft. length of run and is moved back and forth by two hauling lines and two tail lines. One hauling line and one tail line are attached to the deck near each end, and this arrangement keeps the table in alignment at all times. Each hauling line, with its companion tail line, is rove on one drum in such a manner that as one line runs off the drum the other fills the space vacated. This method successfully prevents the cables from overriding and admits the use of a smooth face drum. The two drums are geared to a countershaft which is belt-driven by a 35-h.p. variable-speed induction motor.

Traveling Cranes. To facilitate the installation of heavy exhibits three bays in the Palace of Machinery were equipped with traveling cranes. The center bay has two 30-ton cranes with 5-ton auxiliary hoists, and each adjacent bay has a crane of 20 tons capacity. These cranes have a span of 67 ft. 8 in. and are of standard steel construction, with 3-phase, variable-speed motors. These cranes were all obtained on a rental basis, the sum of \$13,600 being paid for their use,

which amount also includes the erection and dismantling of the cranes.

Refrigeration Plants. Refrigeration service was considered desirable in the Palaces of Horticulture and Food Products, and refrigeration plants were accordingly installed in these two buildings. The apparatus was installed by exhibitors, but was operated at the expense of the Exposition, which in turn sold refrigeration service to various exhibitors and participants. Subsequent events, however, proved that the use of small individual plants, or ice, would have been more satisfactory than a central plant and distribution system, because the needs of the consumers were nominal.

In the Palace of Horticulture the central plant is an exhibit of the Automatic Refrigerating Company. The principal feature of this installation is its automatic control, a thermostatic switch starting and stopping the motor according to the changes in temperature of the refrigerated space. The water for the condenser is automatically regulated to meet load requirements and is shut off entirely when the motor stops. Should the water supply fail the motor will stop automatically and will start again when the water supply is resumed. The plant has a rated capacity of $3\frac{1}{2}$ tons of refrigeration per day. The piping is 1000 ft. long, 11-in. diameter, and is covered with cork insulation. Although this plant receives but little attention, the results are most satisfactory.

The central plant in the Palace of Food Products was installed as a working exhibit by the York-California Construction Company and consists of two double-cylinder, double-acting, vertical compressors—one of 20 tons and the other of 4 tons refrigerating capacity, both belt driven by motors. Brine is chilled and circulated through the distribution piping to the various exhibits. This piping is not covered, as it is cheaper to waste power during the short period of the Exposition than to provide insulation. To prevent waste of water an inexpensive cooling tower was built 4 ft. by 8 ft. in section and 25 ft. high. Spray heads were installed half way from the top of the tower and the air for cooling purposes taken from beneath the building floor and blown through the tower by a 30-in. disc fan. The discharge of air from the tower directly into the building has not proven objectionable.

Repair Shops. Early in the progress of construction work machine and blacksmith shops were fitted up to care for general repair work and later for the manufacture of electric standards and fixtures. All of the iron work used in the construction of the gas and electric standards was fabricated in the Exposition's shops.

ELECTRICAL FEATURES

One of the earliest problems for settlement was that of securing a supply of electrical energy for the construction and operation of the Exposition. Owing to the fact that there were three electrical companies, with steam stations within the city and connections to extensive hydroelectric systems, the Exposition was in a favorable position to negotiate for the purchase of electric energy.

In order to arrive at a figure sufficiently close for the purpose of making a contract for electric service, the areas of the buildings, courts, gardens and avenues were computed and various light intensities assumed for each. Tungsten units were figured for use in the buildings and courts, and magnetite arc lamps for the gardens and avenues. The load

in the concessions area was assumed as being 80 per cent of the connected load in the concessions area of the St. Louis Exposition. The amount of load for exhibitors was guessed at, as there was no information available on this point. These rough calculations indicated that the average peak would be 8500 kw., with a maximum of 11,500 kw. during the winter season when the day load would overlap the evening load. It was decided to compare proposals on the basis of a 12,000-kw. maximum load and a load factor of 30 per cent.

On Feb. 28, 1913, a contract for supplying electric service was entered into with the Pacific Gas and Electric Company, under the terms of which the Exposition was to pay 2 cents per kw-hr. during the pre- and post-exposition periods, and during the actual period of the Exposition a fixed charge of \$18,000 per month, plus an energy charge of 0.6 cents per kw-hr. For the fixed charge named the Exposition was entitled to take loads up to 15,000 kw., but was

FIG. 17 THREE-HINGED ARCH CONSTRUCTION, PALACE OF FINE ARTS

to pay \$2.00 per month per kw. for the excess demand over and above this amount. At the time this agreement was signed, there was every reason for assuming that the maximum load would be 12,000 kw. or more, but owing to the period of financial depression which followed, and the European war as a climax, a large number of prospective foreign and domestic exhibits were withdrawn, and the maximum load realized has not exceeded 8100 kw., with an average maximum of 7880 kw. On the basis of this average maximum and the charge for energy, the cost per kw-hr. has averaged 1.7 cents.

An agreement was entered into with the Pacific Gas and Electric Company, whereby it was to furnish the Exposition, for use during the Exposition and during the construction and dismantling periods, all of the electrical apparatus, instruments, materials and appliances which might be required, except building wiring, searchlight projectors and other special apparatus not in general use by power companies. For the use of this apparatus the Exposition agreed to pay 5 per cent of the cost of the apparatus to the Pacific

Gas and Electric Company as a rental, independent of the length of time the apparatus had been in use, and to pay outright for all apparatus not returnable.

Included in the contract for electric service was the requirement that the power company should install a sub-station on the grounds and a 5000-kw. steam standby plant. This requirement was later modified by an agreement between the Pacific Gas and Electric Company and the Sierra and San Francisco Power Company under the terms of which the Pacific Gas and Electric Company installed its sub-station in the west end of the Sierra and San Francisco Power Company's power house, and received standby service from its 18,000-kw. turbine plant. As the power house mentioned is within the grounds and the plant was to be kept running during the period of the Exposition, it was felt

3-conductor, 3-phase feeders. With the exception of the overhead lines in the concessions district, and the extreme westerly end of the grounds, the distribution is from an underground system.

Secondary Distribution. With the exception of the areas mentioned, where overhead lines are installed, alternating current at secondary voltages for light and power purposes is taken from transformer vaults which are in reality minor sub-stations in which the primary cables terminate and the high-tension switch gear and transformers are installed. All buildings are furnished with energy for light from 3-phase, 4-wire mains connected to the distribution boards on the transformer vaults. This arrangement provides 115 volts from any conductor to neutral, and consumers are served from one, two or three of the phases, depending upon the

FIG. 18. FRAMING OF PALACE OF MACHINERY, SHOWING CONNECTIONS AT INTERSECTIONS OF BAYS, ALSO FRAMING FOR CRANE

that the protection of service thus secured was even greater than under the terms of the original contract.

In fulfillment of the terms of the contract, the 60-cycle, 3-phase energy used by the Exposition is generated at Station A, which is in the southern part of the city. This station has a capacity of 52,000 kw. in steam prime movers and, in case of breakdown or overload, takes electric energy from the power company's 60,000-volt transmission lines which terminate at Martin Station, at the southern boundary of the city, where the voltage is reduced to 11,000 volts. To transmit this energy three 4 0, 3-conductor, 11,000-volt cables run underground from Station A direct to the sub-station on the grounds, known as Station F.

Primary Distribution System. Power from Station F is distributed throughout the grounds by means of fifteen 3-conductor, 3-phase, 4100-volt feeders and two 11,000-volt,

size of their load. Power is supplied from separate transformers and the distribution is at 230 volts from 3-phase, 3-wire mains.

Electric Rates. Electric service is furnished at flat, meter and special rates, as follows:

Flat rate: Electric installations having a connected load to any given service of less than 2 kw. are charged at the rate of \$15 per month per kw. of connected load, with a minimum of \$2.50 per month where the load is 166 watts or less. This rate is based on the understanding that the entire connected load will not be used more than 240 hours per month.

Meter rate: Consumers having connected loads in excess of 2 kw. are provided with meters, and electric service is charged for on the basis of \$2.50 per month per kw. of connected load, and an energy charge of 5 cents per kw-hr., with

a reduction of 0.1 cent for each 1000 kw-hr. used per month up to 20,000 kw-hr. and 3 cents per kw-hr. for the balance.

Special rate: All exhibitors in the main palaces were given lighting service at rates 25 per cent less than the foregoing, and power service at a rate of 3 cents per kw-hr. The connected load was estimated from the manufacturer's rating of the apparatus and in most instances was the maximum demand.

An exception to these rates was made in order to encourage participants in the States and Foreign sites to illuminate their buildings, and no fixed charge was made on lights installed for exterior decorative purposes.

Direct Current System. Direct current for the operation of searchlights and projectors is generated by two 1000-kw., 250-volt generator sets and two 250-kw., 125-250-volt balancer sets. These units are installed at the various load centers in order to reduce to a minimum the distribution copper required, but are all operated in parallel.

Underground Conduit System. The underground conduit system is approximately 30,000 ft. in length, and comprises 300,000 ft. of duct. The short life of the Exposition necessitated an economical design, and a type of conduit construction was adopted based on the use of fibre duct with $\frac{1}{8}$ -in. walls (Linaduct), and wooden manholes. The ducts were laid on a box or trough extending between manholes which varied in size to suit the number of ducts. The space between the ducts and the box was filled with sand sluiced into position with water, except at the entrance to the manholes, where concrete was used for a distance of 4 ft. to prevent the ducts being displaced by cable pulling operations.

The boxes were made up in the mill and delivered in 14-ft. and 20-ft. lengths, which were made continuous by splice pieces nailed to the sides and bottoms. The load on the bottom boards was transferred to the sides by means of 1-in. by 4-in. strips fastened to the bottom and sides and spaced 4 ft. apart, the corners held by iron straps. After the boxes were filled flush with sand, pieces were nailed across the top. This form of construction proved to have great mechanical strength, and there were many instances where building materials were piled upon exposed lines, and spans of 10 ft. or more were left unsupported as a result of undermining for other utility mains, without damage to the conduit. The conduit system was laid before the streets were paved, but was not damaged by the teaming or road rolling. In fact, a

damaged duct or a misplaced one has never been discovered.

Lighting Standards. The design of the foundations for are standards was given careful study, as most of the standards were to be set in a soft dredger fill. The standards fitted with banners, in particular, were liable to blow over in high winds, as the exposed area was large and the arrangement ideal for catching the wind. These poles are 40 ft. high, 13 $\frac{1}{2}$ in. in diameter at the ground line, 4 in. in diameter at the top, and carry from 5 to 7 are lamps which weigh 100 lb. each. The banners have an area of 50 sq. ft. with the center

of pressure from 25 ft. to 35 ft. above the ground line. The other design of are standard has a staff decoration on the top which, owing to its size, shape and weight, presented almost as severe a problem as the banner type.

Considering that there are 200 of these standards, the foundations for which involved considerable expenditure, experiments were carried out with various forms of foundations to determine the least expensive type of construction which would meet the rather unusual conditions. The result of these experiments was the adoption of a reinforced concrete slab placed 6 in. below the ground surface and supported by piling. The piling consisted of 2-in. by 6-in. pieces which were jettied into place in advance of the concrete work. Spikes were driven near the tops of the piling, which were embedded into the concrete, and served to transmit to the piling any uplifting forces due to the turning moment developed by the wind. The concrete slab was made in the form of a cross to insure a sufficient spread with the minimum of material, and a hole was left in the center to receive the pole, which was grouted in after setting. These foundations cost \$35 each, and although storms have been experienced which tore away the banners in some instances, none of the foundations has failed.

Illumination. With the realization that illumination had become a branch of engineering, a specialist in that field was employed to design the general scheme for lighting the Exposition, which was later adopted and made the basis for detailed plans and estimates. Slight changes were later made to obtain the desired effect.

The perfection of the illumination produced is largely the result of an appreciation by the engineers of the aesthetic qualities of the work of the architects and artists, and it was therefore possible to secure their coöperation, which was of the greatest value, particularly in the settlement of prob-

FIG. 19 FRAMING OF PALACE OF MACHINERY

lems relating to color, and the location, scale, mass and decoration of the lighting standards.

The general scheme of illumination adopted was to use flood lighting from hidden projectors and massed lighting from arc standards, exposed sources being used in gardens and along roadways where the treatment admitted of incandescent standards. The illumination was described in detail by the writer in the Feb. 13, 1915, issue of the *Electrical World*.

The flood of light on the various towers is produced by searchlight projectors hidden on the roofs of buildings and outlying structures. For the flood lighting of the 6 towers, the Palace of Fine Arts and the large groups of statuary, thirteen 30-in. and two hundred 18-in. searchlight projectors

illuminated by concealed incandescent lamps which are dipped an orange color. On the towers these lamps are located behind the columns, at the floor levels. To have wiped out the shadows entirely would have resulted in a flat effect, and no feature has contributed more to the charm of the lighting than the treatment of the shadows with color.

A decorative feature is the use of imitation jewels in connection with the illumination of the upper portion of the main tower, where over 100,000 are used, while 25,000 are used elsewhere. The jewels are made of glass and vary in size from 21 mm. to 47 mm. They are cut with facets similar to those of a diamond, and a small mirror is mounted behind each to increase the number of flashes obtainable. These jewels were made in Austria and their cost ranged from 33 cents for the 47-mm. size to 6 cents for the 21-mm. size. Although the jewels are of various colors, most of them are amber. They are mounted in holders which are attached to supporting hooks, allowing them freedom to swing in the air currents. Under the powerful rays of the searchlights the jewels sparkle and glitter and contribute an element of action and color which is most striking. The jewels have never been cleaned and the difference in appearance after 5 months' use is not noticeable.

The flood lighting feature for the building wall surfaces is provided by magnetite arc lamps set on ornamental standard 30 ft. high and spaced from 60 ft. to 75 ft. apart. Two types of standards are used, one having a large curved shield of staff with three openings fitted with orange colored translucent fabric; the other has a combination of three canvas banners painted with heraldic emblems. The design of both types is such that the lamps are not in the line of sight, but allow a small amount of colored light to pass. Lamps were used on these standards in combinations of 2, 3, 5 and 7, depending upon the distance of the standards from the building walls. Some light was reflected back from the building walls, but not enough to illuminate the adjacent avenues, and additional lighting was provided by means of single-light electroliers made of staff and equipped with 250-watt Mazda lamps and 18-in. glass globes.

Similar electroliers, carrying from 1 to 21 globes, lighted the South Gardens, Court of Palms and the entrances to some of the other courts. Special globes were used which, while they contributed a mellow diffused light at night, produced a discordant effect during the day, owing to their whiteness as compared with the color tone of the travertine finish of the buildings. A lacquer, into which color was mixed, was used to overcome the objectionable appearance of the globes.

The globes were all in position at the time it was decided to spray them, and for this purpose a portable rig was made consisting of an air compressor and four potter's wheels, which was moved around from standard to standard, the globes placed on the wheels and sprayed with the lacquer by means of an air brush. The lacquer coating caused some loss of light, but not enough to make a noticeable difference in the illumination.

An element of life is given to the night picture of the Exposition by the buildings appearing to be lighted up inside, which effect is produced by Mazda lamps fitted with tin reflectors and suspended back of the various building openings. The color effects in some locations are obtained by using dipped lamps and in others by painting the glazing.

The kaleidoscopic colors and shapes which appear in motion on the glass dome of the Horticulture building are

FIG. 20 BATTERY TRUCK CRANE WITH EXTENSION BOOM FOR HANDLING STANDARDS

are used. Most of these are fitted with dispersion doors which spread the beams anywhere from 10 to 40 deg., depending upon the design of the strip lenses in the door. In some instances double doors are used, one of which spreads the beam horizontally and the other vertically.

The searchlight projectors are of the manual control type and most of them are equipped with parabolic mirrors, while the balance have Mangin mirrors. The latter type of mirror is not suitable for lighting building surfaces, as it produces a spectrum at the circumference of the field illuminated, but for lighting groups which occupy only a portion of the field this type of mirror is satisfactory. Gelatine color screens are employed in connection with the searchlight projectors and by their use the color tone of the Exposition can be readily changed.

The strong light from the projectors would cause deep and sharp shadows, and to neutralize this effect the shadows are

produced by twelve 30-in. searchlight projectors placed beneath the center of the dome and arranged to project their beams through revolving lenses and color screens. Eight color screens and twenty lenses are used in connection with an opaque sector disc. These three elements are mounted on a vertical shaft and slowly revolved at slightly different speeds. Various combinations of shapes and colors are thus projected upon the dome, but the effects are rather thin, owing to the fact that the quality of glass used does not intercept a sufficient amount of light.

Without doubt the most spectacular feature of the illumination of the Exposition is the so-called scintillator, located on the Yacht Harbor. The equipment consists of forty-eight 36-in. searchlight projectors of the manual control type and is used in connection with pyrotechnic displays and steam effects, in addition to being used nightly in the form of a great fan as a background to the illumination. The color screens used in connection with these lights are wooden frames with gelatine sheets held between chicken netting. The gelatine sheets are waterproofed with spar varnish for protection against moisture. The searchlights are operated by 52 U. S. marines under a commissioned officer.

The illumination of the Exposition buildings and grounds, not including the States and Foreign section, produces a load of 5216 kw., of which 1700 kw. are used for the searchlights, 450 kw. for the arc lights and 3066 kw. for the incandescent lighting. The cost for electric service chargeable to illumination is \$630 per night, and for labor, repairs and maintenance \$125 per night. The lighting of the emergency gas lights costs about \$35 per night, and the gas lighting in the States and Foreign sites about \$40 per night. In round numbers the cost to the Exposition for lighting is \$830 per night, which sum includes all operating costs, but no capital charges.

GAS DISTRIBUTION

Gas for the use of the Exposition and its participants is purchased wholesale from the Pacific Gas and Electric Company and is retailed by the Exposition through a system of high-pressure distribution mains which were installed by the company for this purpose. The gas used is manufactured from oil at the company's Potrero plant and is transmitted across the city at a pressure of 80 lb. Two Thomas electric gas meters measure the high pressure gas supplied to the Exposition. The distribution mains extend throughout the grounds, an 8-in. ring surrounding the main group, with an 8-in. loop into the States and Foreign sites, and a 4-in. loop into the Zone. Other areas are supplied from 4-in., 3-in. and 2-in. mains laid to form loops or rings. Lap welded pipe was used for the 8-in. and 4-in. mains and standard pipe for the smaller sizes. In all there were 100,000 ft. of pipe laid. All joints and connections to the mains were welded by the oxy-acetylene process and the connections were tested with high pressure gas before backfilling.

The various palaces were equipped with low-pressure 4-in. and 6-in. ring mains which were fed at one or more points by 3-in. service connections from the high-pressure mains. Pressure governors within the buildings reduced the gas pressure to 6-in. water gauge, and oil seals were installed close to the governors for protection against an increase in pressure in the domestic distribution system due to a failure of the governor. Consumers located within the Exposition

buildings are supplied from the ring mains, while those in the States and Foreign sites are connected to the high-pressure mains, with a regulator set on their premises to reduce the pressure. In the States and Foreign sites, and on top of all kiosks, high-pressure gas lamps are installed. Each lamp has a small regulator which reduces the pressure to 3 lb., but oil seals are not used in connection with these installations. Some 257 of these lamps are in use, with excellent results. Low-pressure gas arcs are installed on poles along the Zone for emergency lighting. The distribution of gas lamps throughout the grounds is such that in the event of a failure of the electric service, people could get about without inconvenience.

With a view to public safety gas lamps were installed for

FIG. 21 LOCO CRANE WITH EXTENSION BOOM RAISING STATUARY

all emergency and exit lighting. Gas is sold to consumers at the rate of \$1 per 1000 cu. ft. for the first 50,000 cu. ft. used in any one month, and 80 cents per 1000 for a consumption in excess of this amount up to 300,000 cu. ft., at which point a sliding scale is applied which reduces the price to about 70 cents per 1000 cu. ft. for some of the large consumers.

Gas is the only fuel allowed on the grounds, with the exception of plants which are sufficiently large to warrant the employment of an engineer. In such installations the use of oil-fuel is permitted.

The average quantity of gas used on the grounds is from 12,000,000 to 15,000,000 cu. ft. per month.

WATER SUPPLY

Preliminary estimates indicated that the average consumption of water would be about 1,258,000 gal. per day with a

possible maximum of 2,525,000 gal. per day. In the absence of any exact data for guidance, and in order to be on the safe side, the pipe sizes of the distribution system were figured on the assumption that the average consumption would be 2,000,000 gal. per day and the maximum 3,500,000 gal. per day. The maximum rate of flow was assumed to be $1\frac{1}{2}$ times the maximum daily consumption.

Sources of Supply. In view of the fact that there was the possibility of San Francisco acquiring the plant of the

From a careful study of the situation, it was estimated that a supply of 1,000,000 gal. per day could be relied upon during the period of the Exposition, which estimate was to a degree verified during the investigations by the work of a sewer contractor in the vicinity of the proposed plant, who found it necessary to pump 1,000,000 gal. per day to un-water his trench. The first step taken was to construct in the westerly end of Golden Gate Park an infiltration sump similar to that used by the Park Commission for their supply

of irrigation water. This sump was made 200 ft. long, 14 ft. wide and 30 ft. deep. Tongue and groove sheet piling was used to keep out the surface water, while removable screens placed near the bottom collected the water of desired quality. This sump developed a yield which indicated it could be depended upon for 350,000 gal. per day, but owing to the high cost of construction for the output secured, it was decided to try sinking wells, although it was brought to the notice of the engineers that wells had been tried before in that territory and abandoned on account of inability to keep out the sand.

The desperate situation justified taking a chance and a test-well was bored just outside the park, which was brought up to a capacity of 368,000 gal. per day without encountering any difficulty with sand. This well was 80 ft. deep, with an outside casing 20 in. in diameter and an inside casing 16 in. in diameter.

FIG. 22 TRANSFER TABLE, PALACE OF MACHINERY

local water company by condemnation proceedings, the Exposition found it impossible to arrange for a water supply from this source. A survey of the situation indicated the possibility of securing about 800,000 gal. per day from the water supply system of the Presidio and the balance by developing the underground storage waters in and near Golden Gate Park, with a small additional amount of water from wells on the grounds.

The Presidio allowed the Exposition the use of one of the compartments of its storage reservoir and the arrangement was such that when the Presidio's compartment was full the excess would spill into the compartment allotted to the Exposition. This reservoir is at an elevation of 384 ft. and the capacity of one compartment is 3,000,000 gal. As soon as this contract was closed, the U. S. Government allowed the Exposition to tap its 8-in. line to Fort Mason, which passed through the grounds, thus giving the Exposition immediate relief from a threatened shortage of water during the construction period.

Golden Gate Park Supply. No time was lost in making tests for water in the vicinity of Golden Gate Park, for it was generally known that a considerable quantity of water was to be found in that district due to the absorption of the rainfall by the sandy soil. Seepage downward is prevented by a stratum of clay at a depth of from 60 to 90 ft. from the ground surface, but there is a flow toward the ocean at a rate of from 10 to 30 ft. per day.

FIG. 23 HAULING GEAR FOR TRANSFER TABLE

Both casings were perforated with slots having $\frac{1}{16}$ -in. openings, and the annular space between casings filled with gravel ranging from rice to pea in size. Encouraged by the performance of this well, four more of the same size and type were drilled in the same vicinity, varying in depth from 70 to 87 ft. The material encountered was a fine beach sand having an effective size of 0.18 mm. and a uniformity coefficient of 1.55. The wells were all located within an area of 650 ft. square, and it was assumed that while one well would probably yield 260,000 gal.

per day during the Exposition period, mutual interference would bring their combined capacity to about $2\frac{3}{4}$ times the capacity of one well, or 650,000 gal. per day for the five wells.

Filtration Plant. Considering shallowness of the wells and the possibility of contamination due to the water shed being inhabited, it was decided to filter the water and treat it with chlorine gas. Realizing that the plant would probably end its usefulness with the Exposition, a design was adopted in which first cost was the prime consideration. The elements of the plant consist of a measuring chamber into which the water is discharged from the wells and sump, a raw water

FIG. 24 FOOTING OF LAMP STANDARD, SHOWING REINFORCEMENT AND ANCHORAGE

reservoir where the coagulant is introduced, three rapid sand filters and a clear water reservoir. A uniform flume type construction was used for all elements, the adoption of which simplified the framing, foundations and erection. A bulkhead placed near one of the raw water reservoirs forms a measuring chamber 12 ft. 6 in. by 9 ft. 6 in. by 9 ft. 3 in. deep. Two 4-in. by 12-in. submerged orifices are located in this bulkhead. The supply lines from the sump and wells discharge into this chamber and are fitted with control valves actuated by floats located in the raw water reservoir. A differential gauge indicates the difference in levels between the water surfaces in the measuring chamber and raw water reservoir, from which the rate of flow is determined.

The raw water reservoir is 64 ft. long by 12 ft. 6 in. wide and 8 ft. deep, its size having been determined by the period of time required for coagulation with four filters operating at maximum rate. The treated water flows from this reservoir to the filters through a 2-ft. by 3-ft. flume located between the row of filters. The supply to each filter is controlled by a shear valve located in the side of the flume. At the far end of the flume is an overflow weir which comes into use in case the water level in the raw water reservoir exceeds the predetermined height.

Three filters, each rated at 500,000 gal. per day, are in operation, but space and pipe connections are available for a fourth unit should the necessity arise. The units are 14 ft. 8 in. long, 12 ft. 6 in. wide and 8 ft. deep. The collector system employed is a departure from the usual types and has been most successful in operation. The design was

developed by Prof. Charles Gilman Hyde, and in addition to its effectiveness has the merit of low first cost. The collector in each filter consists of a header, rectangular in section, bolted to the bottom of the filter. The effluent pipe is run through the bottom of the filter to the center of the header from which point the header is tapered so that the loss in head is fairly uniform throughout its length.

On the top of the header, openings are provided for the 3-in. nipples which make the connection to the $2\frac{1}{2}$ -in. lateral pipe. These laterals are placed on 6-in. centers and extend the full width of the filter. Holes $\frac{5}{16}$ in. in diameter and 3 in. apart are located on the under side of the laterals. The loss of head through each of these small holes being the same, and great as compared with the losses elsewhere, insures a uniform collection of the effluent. Coarse gravel was placed in the bottom of the filter to a point 2 in. above the laterals, then three layers of graded gravel, each 3 in. thick, followed by 26 in. of sand having an effective size of 0.35 mm. and a uniform coefficient of 1.5.

The depth of water over the top of the sand is 30 in. The effluent flows from each filter through an 8-in. riveted steel

FIG. 25 BANNER TYPE LIGHTING STANDARD

pipe to the clear water reservoir, where an effluent controller of simple design is installed. The controller is set in a compartment located within the clear water reservoir with water connection thereto through a submerged weir. The level of the water in this compartment is kept at a constant height by a float actuating the controller, which insures a fairly constant rate of flow. Should the water in the clear water reservoir reach the overflow point, an auxiliary float closes the effluent controller. Wooden floats are used throughout and the simplicity of the effluent controller may be realized by the fact that three of them, 8 in. in size, cost less than \$50 to make. All of the measuring or controlling

devices used in this installation are home made, and while some of the equipment may appear to be crude it does the work with all of the accuracy essential to operation.

The washing of the filters is done by the reverse current method, the water being forced through the collector system at a high velocity. A 10-in. centrifugal pump is used for this purpose and the rate of washing is 2-ft. vertical rise per min. in the filter, which is equivalent to 15 gal. per min. per sq. ft. of sand surface. Washing at this rate raises the sand bodily about 12 in. and keeps it in motion. Two wooden V-troughs in each filter collect the wash water. No appreciable disturbance of the gravel has been noted, although no means have been provided to prevent it. It takes about 5 min. to wash a filter, the wash water being applied for 2

form scale, and it has been found that the quantity determined from the gauge readings checks within 1 per cent of the weighed quantity. The chlorine is applied at the rate of 3 lb. per 1,000,000 gal. of water, and bacteriological tests have demonstrated that the water is at all times perfectly safe for drinking purposes.

Main Pumping Plant. The water is taken from the clear water reservoir and pumped to the Presidio reservoir by three 5-stage 6-in. centrifugal pumps, each rated at 500 gal. per min. against a pressure of 220 lb. These pumps are belt driven by 125-h.p. induction motors. The pump house is located alongside of and about 5 ft. lower than the clear water reservoir, so that the pump suction lines are under a pressure head at all times. The main pumps force the water

FIG. 26 COURT OF FOUR SEASONS, WITH SCINTILLATOR IN DISTANCE

min. Owing to the water being practically free from turbidity, it is only necessary to wash the filters every 10 hours.

Clear Water Reservoir. The clear water reservoir is 96 ft. long, 12 ft. 6 in. wide and 7 ft. 6 in. deep and holds 60,000 gal. of water. From the bottom of this reservoir, and located on the side directly opposite that on which the effluent controllers are situated, three 6-in. suction pipes are run, one to each of the three units in the main pumping plant. Over that part of the reservoir where the controllers are installed is a house which contains the sterilizing equipment.

This equipment is the exhibit of the Electro Bleaching Gas Company, of New York, and consists of a gauge board, shut-off valves, gauges and a pressure reducing valve. The quantity of gas applied is indicated by the position of a small glass float located within a tube.

The apparatus is easy of adjustment and does not require a skilled attendant. In order to keep a check on the quantity of chlorine used, the cylinder in use is kept on a plat-

form scale, and it has been found that the quantity determined from the gauge readings checks within 1 per cent of the weighed quantity.

Trouble with Wells. While no trouble has ever been experienced with the test well mentioned heretofore, the other four wells gave trouble from the start. It is hard to explain this difference, as the wells were all of identical construction and the formation encountered was the same for all. The pumps used in these five wells are vertical, 3-stage, centrifugal pumps, belt-driven by 20-h.p. motors, and operate at 1400 r.p.m. against a 75-ft. head. A foot valve was placed below the pump, but as it was the cause of the pump becoming choked with sand it was discarded and a check valve placed in the discharge line from the pump. Each of the wells in turn started to sand up as soon as any considerable amount of water was pumped, with the result that the pump soon choked and it became necessary to withdraw the pump and sand-pump the well.

Although the pumps were supposed to be adapted for

handling water containing sand, the bronze bearing bushings were in some instances cut out with one day's operation. This trouble was largely overcome by discarding the tubes which enclosed the shafting, and using leather rings above and below each bushing, securely fastened thereto and fitting snugly on the shafting. By operating the pumps at capacities between 60 and 100 gal. per min., depending upon the well, continuous flow could be obtained, but a certain amount

FIG. 27 APPARATUS FOR APPLYING CHLORINE TREATMENT TO WATER SUPPLY

of sand would be discharged and the wells would soon fill up with sand. In order to avoid the expense and delay incident to removing the pumps and sand-bailing the wells, an air ejector was made which could be lowered into a well without disturbing the pump. By this means 50 ft. of sand was taken out in 3 hours, a large part of the time being consumed in putting down and removing the piping. The removal of such large quantities of sand soon caused the ground around the casing to cave, with resulting disturbance to the foundations of the building and equipment.

It became evident that the wells as they stood would never give satisfaction, and it was decided that their failure was due to the size of the gravel which had been placed in the annular space between the outside and inside casings. In the belief that a suitable material could be found which would keep the sand out and at the same time allow the water to flow through freely, it was decided to experiment with various mixtures of sand and gravel and different perforations for casings.

Flat test plates 8 in. by 12 in. were prepared, each having a different size of perforation. These were tested by placing them in a wooden frame box with trial mixtures of sand and

gravel placed between the plates. Above the plates a quantity of the sand was placed that had been taken out of the wells, and water pressure applied. The flow of water was measured by meter and the pressures taken for different rates of flow. The result of these experiments was the selection of a naturally graded beach sand which had an effective size of 0.42 mm. and a uniformity coefficient of 2.18. It was determined that, with the use of this, sand plates could be used having a perforation of $\frac{1}{32}$ in. in width, and that the fine material from the wells would be held back even when the velocity through the perforations was as high as 0.75 ft. per sec. As the maximum velocity through the perforations under operating conditions would never exceed 0.5 ft. per second, it was considered safe to use this material.

As the wells, except No. 1, were not giving more than half the yield contemplated, it was decided to put down additional wells, making use of the data which resulted from the experiments. The contractor's price for the old wells was \$7.50 per ft., and it appeared that new wells could be put down cheaper with the Exposition's force by using a hydraulic ejector instead of a well driller's standard equipment. The site chosen for the trial well was close to the main pipe line where water would be available at 175-lb. pressure. The hydraulic ejector or sand-pump was made with standard fittings, but had a machined brass throat piece. The well drilling rig and ejector are shown in the illustrations.

In starting, the bottom section was made up of a 5-ft.

FIG. 28 FILTRATION PLANT. FILTER HOUSE IN FOREGROUND

length of inner and outer casing, the inner casing being tapered to the diameter of the outer at the bottom and both riveted to a forged steel shoe. A hole was dug 5 ft. deep at which point water was encountered, and the bottom section set in place. The hydraulic ejector was placed inside and excavated the material down to the shoe. The first 15 ft. of casing went down of its own weight very rapidly, but for the balance of the distance it had to be forced down by means of the long lever shown. The maximum force applied was about five tons and the average rate of travel of the casing was 1 in. per min.

After 25 ft. of casing had been placed it was found that the well was badly out of line due to the removal of too much

material from one side. The casing was straightened up by putting a jet down one side and keeping a strain on the top of the casing by means of block and tackle. Guides were put on the ejector suction to keep it centrally located, and no further trouble was experienced with the casing getting out of line.

It required five days to complete the well to a depth of 60 ft. The outer casing used for this well was 22 in. in diameter, No. 12 gauge steel, with collar joints, each section being

FIG. 29 RIG USED FOR DRILLING NO. 6 WELL

30 in. long, with perforations $\frac{1}{16}$ in. wide by $13\frac{1}{4}$ in. long. The inner casing was 16 in. in diameter, of similar construction, but with perforations $\frac{1}{8}$ in. wide. The area of the perforations was estimated at 0.0329 sq. ft. per running foot of pipe. Perforated casing was used throughout the depth of the well except for the bottom section and the upper five sections. The material used in the annular space between the inner and outer casings was that determined by experiment, and was put in place as the casing was lowered.

The well, on test, developed a capacity of 200 gal. per min. without discharging sand. Instead of drilling additional wells of this type, which would take time and involve additional pumping equipment, it was decided to reconstruct all of the other wells, except No. 1.

Efforts to remove the inside casing met with no success. Fortunately, the diameter of the deep well pumps was such as would allow the placing of a $13\frac{1}{2}$ -in. casing inside the well. One of the wells was equipped with this size of perforated casing, and the space between it and the 16-in. casing was filled with the same grade material as that used in the No. 6 well. The installation of this casing was a comparatively simple matter and required about eight hours' work for an 80-ft. well. Under test the remodeled well operated continuously at a rate of 243 gal. per min., and no sand appeared in the discharge. The use of the additional casing and the sand increased the resistance to the flow of the water, and for the same yield the water surface had to be drawn down about 30 per cent lower than before. The rest of the wells were reconstructed in a similar way, and have all been brought up to capacity, without trouble from sand.

Other Sources of Supply. In October, 1913, three wells

were sunk in the grounds which were of considerable use during the construction period, but owing to the questionable character of the water from a sanitary viewpoint these wells are no longer used, except for filling pools. Water is also taken from the Spring Valley Water Company for the Fisheries exhibits and to supply an occasional shortage.

Amounts of Water Used. Below is given a table showing the quantities of water used and the sources of supply from February 20 to July 31, inclusive:

Month	Government water	Park water	Spring Valley water	Zone wells	Total (gal.)
Feb. 20-28.....	723,037	226,775	204,000	1,337,500
March.....	733,523	347,200	106,000	34,703	1,228,965
April.....	724,270	591,760	29,593	1,345,617
May.....	612,887	564,636	19,116	1,205,636
June.....	473,157	1,057,750	54,910	1,585,694
July.....	398,460	1,060,094	138,696	1,597,250

It will be noted that the supply obtained from the Presidio fell far short of the estimated amount, 800,000 gal. per day, and that the Golden Gate Park supply has been increased materially over the assumed yield of 1,000,000 gal. per day.

FIG. 30 PERFORATED WELL CASING AND HYDRAULIC EJECTOR

Additional wells in the vicinity of the park are being developed which will probably contribute 500,000 gal. per day to care for the increased consumption to be expected in August and September, and offset a possible decrease in the yield of the old wells.

The maximum draft noted at any time shows that water was being used for short periods at the rate of 4,250,000 gal.

per day. On average week days 60 per cent of the total consumption is used between the hours of 8.00 a.m. and 4.00 p.m., and on Sundays (when there is no irrigation) about 47 per cent during these hours.

Cost of Water. The cost of water per 1000 gal. from the Golden Gate Park plant is 1.517 cents for pumping from the deep wells to the filters, 0.974 cents for filtering and treating with chlorine, and 3.935 cents for pumping to the Presidio reservoir, making a total cost of 6.426 cents per 1000 gal. delivered in storage. These costs cover operation and maintenance only. The water obtained from the Presidio is sold to the Exposition for 7½ cents per 1000 gal., while that taken from the Spring Valley Company averages 19½ cents per 1000 gal.

Quality of Water. Tests of the water from Golden Gate Park are made weekly by the Federal Laboratory, and in no instance has the treated water failed to meet the U. S. Government requirements for potable water. The following is a representative test:

Raw Water,	Gas in 10 c.c., colon types
	count, 100 per c.c.
Effluent,	Gas in none of the specimens
	Count, 12 per c.c.

Construction Costs. The filtration plant, including the pump houses for the main pumps and wells, together with the pipe line to the wells, cost \$14,575. The cost of the first five wells was \$3,975 and that of the No. 6 well \$255. The cost of the sump was \$14,979. The pumps, which included three 5-stage main pumps, one 4-in. vertical centrifugal sump pump, five 6-in. deep well pumps, and one 10-in. wash water pump, cost \$4,962. The electrical equipment was rented. The cost of the pipe line from the pumping plant to the Presidio reservoir, and from the Presidio reservoir to the Exposition grounds, was \$37,150. The total expenditure to develop a water supply and deliver it to the Exposition grounds was \$77,000.

TELEPHONE SYSTEM

One of the important activities of the Exposition is the operation of the telephone system within the grounds. An arrangement was made with the local telephone company, whereby the necessary equipment was rented to the Exposition and the latter installed the distribution system. An 18-position switchboard was installed in the Food Products building, at which point the trunk lines from the local company were terminated. In laying out the distribution system, the grounds were divided into sections and cables run to the approximate center of each. Cross connection boxes were installed at these points, from which feeder cables were run where required. The conduit system installed for the electric distribution was also used for the underground telephone cables.

In the buildings twisted pairs were run in rings along roof trusses or under the floors, while in the Zone district the subscribers were connected to a cable fastened to the fences in the rear of the concessions. In the States and Foreign sites cables were run to a few of the large buildings, and feeder cables from these points to other buildings. The underground distribution system required the installation of 47,700 ft. of cable (9,474,800 ft. of wire), of which 4300 ft.

was 400-pair cable. Over 1,100,000 ft. of duplex wire was used in the overhead distribution.

With the view of facilitating the work of the Exposition's forces, private branch exchanges were installed in a number of the large departments. These exchanges had interconnecting lines in addition to direct lines to the main board and to one of the exchanges of the telephone company, the latter line being used only for outgoing calls. Fifteen attended pay stations with 100 booths were installed, one in each of the main buildings, three on the Zone and two at the entrances. These were later changed to non-attended stations as the income did not warrant the expense of attendants.

In addition to the foregoing, 53 telephones with coin collectors were installed at convenient points around the grounds. The Exposition installed 732 telephones for its own use and 1244 for the needs of its subscribers and pay stations. Subscribers are charged on the basis of the equipment required, the charge for a 1-party station being \$6 per month. All services are metered and the rates for calls terminating within the City vary from 5 cents to 3½ cents each, depending upon the number used by the subscriber in any one month.

No one element of the organization contributed more to the successful opening of the Exposition on time than did the telephone department. The demands upon the telephone system around opening day were unprecedented, the number of calls handled per day reaching 49,500.

CONCLUSION

The president of the Exposition, Mr. Chas. C. Moore, has been identified with many successful engineering enterprises, and when he undertook the responsibility of this great project he selected an engineer for the position of Director of Works. At previous expositions the Director of Works had always been an architect, and there was much criticism over the appointment of an engineer for this position, but the choice has been fully justified by the artistic results obtained and the completion of the Exposition on time and within the amount appropriated, a performance not usually associated with the construction of expositions or other monumental groups of buildings. There was some fear that with engineers in charge, whose efforts might be expected to be in the direction of keeping the costs within the allowances, there would be decisions which would seriously affect the aesthetic value of the various decorative features, and would stifle the zeal of the architects, sculptors and artists. But while the designers had their heads in the air, the engineers had their feet on the ground and many features were changed or eliminated to keep the expenditures within limits. These changes were made without friction, as the engineers were appreciative of the efforts of the architects, sculptors and artists and thereby secured their assistance toward the desired end.

The Exposition engineers have had an unusual opportunity not only to carry out their ideas in matters of construction, but to manage the operation of a great enterprise. Investigation will show, in this instance, the versatility of the engineer and his fitness by training and temperament to analyze a situation and to foresee difficulties and provide against them.

MECHANICAL ENGINEERING AT THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION

BY G. W. DICKIE, SAN FRANCISCO, CAL.

Vice-President of the Society

THE Panama-Pacific International Exposition shows very clearly the changes during the past 22 years, or since the Columbian Exposition, particularly in mechanical engineering. At the lake front of the Chicago Exposition, there was a full-sized model of the first three battleships then building for the U. S. Navy. This model was built of bricks and concrete on piles, and in it the Navy Department had a very instructive exhibit. To-day the actual battleship, thus portrayed on Lake Michigan, lies in front of our Exposition as an illustration of a type now passing away, but with a twenty years' history to think of, of which the model on the lake shore gave no intimation.

The first thing that the mechanical engineer observes on entering the Palace of Machinery at the Panama-Pacific International Exposition is the entire absence of the steam engine. There is not a steam engine of any kind in operation, nor a steam boiler under steam. This is the first international exposition where the steam engine, as a prime mover, has been so conspicuous by its absence. On first thought the engineer might take this as evidence that the steam engine, after a century or more of development and a service to industry beyond reckoning, had suddenly reached a stage of innocuous desuetude and had ceased to rank as the greatest machine that the mechanical arts had produced. On second thought, however, he would have to admit that, of all the power developed by the combustion of fuel, more than 90 per cent is developed in the cylinders of steam engines or the rotors of steam turbines. His third thought would probably bring him to the conclusion that the steam engine, in all its varied forms, has reached that stage of development when no striking improvements can be looked for; in fact, the steam engine has in a sense reached its prime, and may be expected to continue doing a large proportion of the work rendered possible by the combustion of fuel, either liquid or solid. The fact that California is a great fuel oil producing state may be one reason why the steam engine forms no part of the machinery exhibits; yet the great bulk of California oil used for fuel is consumed under steam boilers.

There is quite a large display of gas engines in the Palace of Machinery, the Transportation Palace, and the Palace of Agriculture. These engines may be classed as:

(a) *Marine Engines, Otto type, constant volume class*, for distillate fuels such as gasoline and kerosene. In this class there are some fine exhibits, such as the Standard Gas Engine Company's exhibit, showing a good line of well designed and carefully finished engines from 100 h.p. down to small sizes. The Union gas engine, shown cut open to illustrate the movements of piston and valve gear, is a fine type of marine gas engine. The Gas Engine and Power Company and C. L. Seabury Company show interesting examples of engines.

The Van Blerck Motor Company exhibit some handsome engines of attractive design, which present new features.

The Imperial Gas Engine Company have an attractive exhibit of substantial-looking engines; while others in the same class, such as the Buffalo Gasoline Motor Company, the Wisconsin Machinery and Manufacturing Company, the Loew-Victor Engine Company and the Waterman Marine Company are all well worthy of study. This type of marine gas engine is well represented at the Exposition.

(b) *Marine engines, Otto type, constant volume class*, with injection for heavy oils. Of this type there is but one example, that of August Mietz. It is a well designed and strongly built engine.

(c) *Marine Diesel oil engines*. In this class there are two exhibits—that of the New London

Ship and Engine Company and that of the Fulton Manufacturing Company. The first-named works under a load of about 80 per cent of full power, the normal power being 200 horsepower. These engines illustrate the present state of the art in Diesel engines of moderate power.

(d) *Stationary engines, Otto type, constant volume class*, for distillate fuels such as gasoline and kerosene. Of this class a great variety is shown, suitable for a wide range of work. Mention might be made of the exhibit of the International Harvester Company, which shows these engines designed for all purposes to which motors can be applied on the farm and all other rural work. There is a rich field in this exhibit, which gives information as to the best way to hitch up a gas engine to almost any kind of work.

The Western Gas Engine Corporation exhibits stationary gas engines which present some features worthy of study. These engines have an unusually long stroke for gas engines, and were the first to introduce water into the carburetor. The valve gear is very simple, with free-moving parts operated by a rod from a single eccentric.

A striking feature of the mechanical engineering exhibits at the Panama-Pacific International Exposition is the entire absence of the steam engine.

In presenting his paper Mr. Dickie said that while the steam engine was advancing to the place it now occupies and many improvements were being made, the builder with something new was ready to show his best work at an exposition. This great prime mover has now reached maturity and will only take second place when the internal combustion engine has reached such a robust maturity as to enable it to do on a much smaller diet what our great steam engines are doing.

Presented at the Panama-Pacific International Exposition Meeting, of the Society, San Francisco, September 1915. The paper may be obtained in pamphlet form; 15 cents to members, 30 cents to non-members.

The Doak Gas Engine Company and the Bessemer Gas Engine Company show some good work under this class. The Standard Gas Engine Company's exhibit is also well worthy of attention.

(c) *Stationary engines, Otto type, constant volume class, with injection for heavy oils.* Under this type some very good exhibits are shown, notably those by August Metz and the Bessemer Gas Engine Company.

(f) *Stationary engines, Otto type, constant volume class, for gaseous fuels.* In this class there are two exhibitors, the Standard Gas Engine Company and the Western Gas Engine Corporation. As the arrangements of valve gear, etc., of these engines are quite different in design and function, they offer a good opportunity for comparison.

(g) *Stationary Diesel oil engines.* In this class there are two exhibitors, the Busch-Sulzer Bros. Diesel Engine Company and the McIntosh and Seymour Corporation. Both show fine examples of vertical engines of 500 h.p. each and both illustrate the best that these makers produce. Each engine is operating with Star distillate, which is probably the nearest to California crude oil with which it is safe to work these engines.

In the special types of gas engines or motors shown in the Transportation building, a large and varied display illustrating their application to automobiles, motor trucks and motor cycles, gives ample opportunity for study in this interesting field. The beautiful workmanship on many of these show the taste and skill that has been brought to bear upon the development of this immense industry.

California is not only rich in liquid fuel, making it an ideal home for the internal combustion engine, but the whole Pacific Coast is a land of liquid power, ready to be used without the necessity of burning anything to produce it. The winter snows on the high Sierras and other mountain ranges forming the eastern boundary of the Pacific slope are the source of this vast accumulation of stored-up energy, which, in the past thirty years or so, has been more and more converted into electrical energy and carried for hundreds of miles to the points where it is needed, to operate factories and street cars, light cities, warm houses and cook food. It is not surprising, therefore, that the most impressive exhibit in the Machinery Palace should be that of the Pelton Water Wheel Company. The writer felt his inability to do justice to this splendid example and asked help from W. A. Doble, chief engineer of the Pelton Water Wheel Company and the designer of much of the display made, who kindly furnished a description from which the following is taken:

It being impossible to secure water, either in sufficient quantity or under pressure desirable for driving hydraulic prime movers, an effective combination of turbine pumps, drawing water from a common sump, and discharging, through control devices and pipe lines of the types customarily employed in hydroelectric practice, into water wheels

of both the tangential and turbine types using the sump as a tail race, has been worked out.

The operating division consists of two sections:

- a A high head pumping project combined with a high head hydroelectric development where water economy is important, and employing tangential water wheels.
- b A deep well pumping project combined with a medium head hydroelectric development, employing mixed flow turbines.

The high head pumping plant consists of a Pelton-Doble turbine pump, driven through a flexible coupling and herringbone speed-increasing gears by an internal combustion engine. The high speed shaft of these gears turns at 1800 r.p.m., the efficiency of transmission at full rated load of 150 h.p. being in excess of 98 per cent.

FIG. 1 500-H.P. DIESEL ENGINE EXHIBITED BY BUSCH-SULZER BROS. DIESEL ENGINE CO.

The engine is a 6-cylinder vertical type, developing 180 h.p. at 350 r.p.m. It uses heavy oil up to 18 deg. Beaumé for fuel and operates on the 4-stroke cycle with maximum compression not exceeding 450 lb. per sq. in. No ignition difficulties are experienced with this low compression.

The pump is a single stage uni-diffusion type, having a capacity of 1100 gal. per min. against a head of 300 ft. The discharge line, after passing through an 8- and 6-in. venturi ring, connects to a Pelton-Doble tangential unit, rated at 100 h.p. under 300 ft. head and operating at 300 r.p.m. This unit is of the single overhung, two-bearing type, with the armature of a 75-kw., 250-volt engine-type direct current generator carried between the bearings, and a flywheel overhung on the shaft end opposite the tangential runner.

Water from the high-pressure pump is applied through a needle nozzle, governing being accomplished by an oil pressure type governor mounted on the nozzle casting, and actuating the needle directly through suitable link and rock-shaft connections. An auxiliary relief needle nozzle avoids

excessive pressure rise in the pipe line and minimizes water waste during governing cycle. The needle of this nozzle is connected to a spring-controlled oil cylinder, known as the cascade cylinder. Ports, adjustable from the outside of the cylinder, determine the time element of piston travel. The same link and rockshaft system that actuates the main needle nozzle is connected to the piston of the cascade cylinder, the relative motion (and thus the nozzle area) being equal and opposite in direction when the time element of the cascade cylinder is zero. With this setting, the auxiliary nozzle merely acts as a synchronous bypass, and the water quantity is constant. Where water economy is of importance, the time element of the cascade cylinder is so adjusted that a rate of closing of the main needle which does not raise the surge pressure to a dangerous point will not open the auxiliary needle. Higher closing rate opens the auxiliary needle,

investigations, and more than 800 tests have been conducted by independent engineers and the staff of the Pelton Water Wheel Company. During the autumn semester of the local universities, 1915, additional tests will be conducted by senior students of the engineering departments.

The central feature of the entire exhibit is a Pelton-Doble single, overhung-runner, single-discharge turbine, rated at 20,000 h.p. under 500 ft. head, at 360 r.p.m. The entrance valve, casing, draft tube and governor are assembled complete; the runner, of bronze with steel hub and forged wearing rings, and fitted with leakage evacuator, is displayed on a separate pedestal. The main valve, of the butterfly type, is 66 in. internal diameter, with body of annealed cast steel.

Two runners, each rated at 10,000 h.p. under 1350 ft. head at 360 r.p.m., are displayed. These are of the chain-con-

FIG. 2 500-H.P. DIESEL ENGINE EXHIBITED BY MCINTOSH AND SEYMOUR CORPORATION

which is then returned to closed position by the compression springs of the cylinder mounting at a rate that will not cause dangerous surge pressures. This is the position of maximum economy.

The deep well pumping plant consists of a Pelton-Doble bore-well type turbine pump, with a capacity of 4500 gal. per min. against a head of 60 ft. and driven at 1760 r.p.m. by a vertical motor mounted on the pump pedestal. The maximum diameter of the pump is 22½ in., permitting its easy entrance into a 24-in. bored well.

The discharge orifice has a diameter of 14 in., and has, bolted directly to it, a riveted steel pipe line which leads to a Pelton-Francis turbine. A venturi ring, 18 in. in diameter, is set in this line. This unit operates under a head of 50 ft. and develops 50 h.p. at 1400 r.p.m., an unusually high specific speed.

The entire operating division is arranged for laboratory

needed type, with ellipsoidal cast steel buckets. The jets for these units are 7 in. diameter, and are projected from deflecting needle nozzles with motor operated manual controlled needles and governor controlled deflection. One of these nozzles, assembled complete with motor, and three needles, pedestal mounted, are displayed. A single bucket of the chain connected type, taken from a wheel rated at 14,000 h.p. under 870 ft. head at 200 r.p.m., is also displayed. A number of water motors of standard and special design complete the tangential section.

In the governor section are displayed a group of self-contained oil pressure type governors, of 5000 ft.-lb. drawbar effort, and, in conjunction with a standard mounted tangential unit, an enclosed type of oil pressure governor having a drawbar effort of 80 lb.

The exhibits of machine tools are not very numerous and, outside of two very notable exhibits, there is nothing in this

line that requires the attention and study of the mechanical engineer who has a fair knowledge of the modern machine tool. Before examining the machine tools it would be well to inspect the exhibit of the Timus Olsen Testing Machine Company as the records produced by such machines form the foundation work for all modern machine tool design. The mechanical engineer finds in this exhibit, which is probably the best in its class that has ever been exhibited by one maker, much food for thought and many admirable ideas in design.

Testing machines and apparatus for engineering research and development may be arranged in two main groups: *a* Apparatus and machines for testing structural materials

built by Mr. Olsen for boiler plate manufacturers. Soon after, about 1870, he built ten such machines for the different branches of the Boiler Inspection Service. Following this development, the technical and engineering schools began to install such machinery. One of the first—if not the very first—was bought from Mr. Olsen by Dr. R. H. Thurston for the Stevens Institute of Technology, Hoboken, N. J.

As time passed the testing machine was changed in design and improved and put to more constant and varied use by all manufacturers of structural materials, as well as large users, and also in technical schools, where its use developed laboratories with apparatus of larger and more diversified forms and functions to include investigation of the more

FIG. 3 PELTON WATER WHEEL CO.'S EXHIBIT, SHOWING 20,000-H. P. PELTON-DOBLE TURBINE

in the form of specimens, as well as the testing of complete designs and structures. *b* Apparatus and machines for testing the materials from which tools are to be made, as well as testing the finished tools.

In the United States prior to 1870, very little progress was made in apparatus for ascertaining the actual strength of materials. One device may be mentioned as used by the U. S. Board of Ordnance for testing the cast iron used in gun making. We know also of one hydraulic press used by Captain Eads for testing the members of the first bridge over the Mississippi River. About 1870, the U. S. Government established the Bureau of Boiler Inspection in connection with the U. S. Steamboat Inspection Service. This bureau formulated rules which required that all boiler plates should be tested by having a coupon from each plate subjected to tensile strain for determining the breaking strain, as well as the yielding point or elastic limit, also the reduction of area at the breaking point and the elongation between two points. Hence came the inquiry for and the development of the commercial testing machine.

The first machine of 40,000 lb. capacity was designed and

varied character and direction of stress to which materials are subjected in modern design.

In group *b* are classed what are termed efficiency testing machines. These machines are of more recent development, although a simple machine of this class was shown at the Centennial Exposition, 1876, in a file manufacturer's exhibit; it was probably made by him to demonstrate the most efficient method of file cutting, as well as the most reliable material for file making and the best method of tempering. Nothing more was publicly shown in this line until a few years ago, when Edward Herbert of Manchester, England, placed on the market his file testing machine and a little later his machine for testing the efficiency of tool steels, especially modern high speed steels. A few of these machines are in use in this country. These two English machines are shown in Mr. Olsen's exhibit at the Exposition.

A few years ago, Mr. Olsen was called upon to design a machine for testing the efficiency of drills, taps and dies. About two years ago this was worked into a practical machine for the Philadelphia Navy Yard and has proved satisfactory, filling all the requirements for this purpose. Later,

by additional attachments, this machine has been perfected so as to make a universal tool as well as a tool steel testing machine. This machine in its newest form is shown in the Olsen exhibit; it will test tool steel, lathe and planer tools, nulling cutters, drills, taps, dies, rimers, files, and hack saws, thus forming a practical efficiency testing machine for determining the quality of most tools as well as the most effective way to make and use them.

The Olsen exhibit is well worth a careful study by the mechanical engineer. Mr. Olsen himself is usually at the exhibit and he looks upon this fascinating collection of testing machines as his own children. As he knows all their little weaknesses as well as their good qualities, an hour's conversation with him is a liberal education in this subject. Here the observer will find the universal testing machine and instruments, spring testing apparatus, cement, concrete and road material testing machinery; cloth, yarn, paper, rubber and leather testing machines; oil testing machines, transverse testing machines, and special testing machines including im-

FIG. 4 CENTRIFUGAL PUMP AND HIGH SPEED TRANSMISSION.
PELTON WATER WHEEL CO.'S EXHIBIT

pect, indentation, vibration, bending, hardness, endurance, torsion, and efficiency testing.

It is unfortunate that some of the largest machine tool makers of this country who had reserved a large amount of space in the Machinery Palace should have withdrawn from participation in the Exposition on the outbreak of war in Europe under the impression that the Exposition could not be a success under the conditions. This is to be regretted, as it leaves a gap in a very important part of the machinery department that the mechanical engineer will not fail to observe. Nevertheless, there are some notable exceptions whose presence makes this condition much less felt than it would otherwise have been.

Among these exceptions the engineer will not fail to notice the splendid collection of both automatic and semi-automatic tools exhibited by the Warner and Swasey Company. This company shows ten tools, several of them being of new design; the tools are all shown in operation and are attracting the favorable criticism of our best mechanics. Their new universal turret lathes are powerful tools and have some remarkable features. Because of their superior strength and rigidity and the fact that each carriage with its independent feeds is able to operate simultaneously, the lathes are enabled to produce a very large amount of work. They have equal facilities for both bar and chucking work. They have geared

heads with splash lubrication. As many as eleven cutters may be used in the turrets and carriages of these lathes, all cutting at the same time and in one set up.

The other tools exhibited by this company belong to their line of screw machines and plain turret lathes which are so well known as the product of the Warner and Swasey Co. and are all characterized by the same scientific design and careful workmanship. The automatic boring and tapping machine used by all the large manufacturers of steam and water fittings for boring, facing and threading their outlets, valves, and joints is also shown in operation. This machine finishes unions as fast as the operator can put them in the chuck and an average of 350 one-inch unions are turned out in a day of nine hours by this machine.

Another exhibit that has given character to the display of machine tools at the Exposition is that of the Morton Manufacturing Co. This is an exhibit of draw-cut shapers, traveling head planers and key-seating machines. The draw-cut type has been developed by this company and lends itself to heavy cutting to a remarkable degree. The whole stress of cutting draws the work solidly and directly against the face of the main casting of the machine and eliminates the stresses from the table rail or the upper bolts holding the table as in the usual type of shaper. The tool arm or ram is under tensile stress in cutting, which tends to reduce or eliminate vibration; when the ram or arm is in compression, the heavier the cut the greater the danger of vibration. One feature of this type of shaper or planer is the facility it offers of shaping to lines, as the latter are on the outside in view of the operator and are not broken or destroyed by the tool as it leaves the work. The tool beginning its work on the face next the operator, the lines on that face can be worked to very accurately as they are not broken or destroyed until cut out by the tool itself. This feature is of great value to the operator as well as the owner of the tool. There is an adjustable back bearing which forms a stop or abutment to the end of the vise when planing parallel with the jaws. With this stop it is only necessary to clamp the work sufficient to hold it as the thrust of the cut comes against the back bearer or stop. As the drawing or pulling cut overcomes vibration, it is possible to make forming tools to be used in these machines at a moderate cost. Rounding tools, either concave or convex, can be made of various radii for producing correct curves in finishing parts of connecting rods, etc. Cutters can also be used for machining parallel openings cutting down both sides at once. Being the originators of the draw-cut principle as applied to this class of machines, the makers have consistently followed up every indication offered by their extended use leading to further improvement in design and operating function.

In the collective exhibit of Fred. Ward and Sons there are shown some very good machine tools, notably those by the American Tool Works. The engine lathes shown are well constructed modern tools with easily adjusted feeds and with speeds especially adapted and designed for electric drive. They are capable of caring for the service demanded by the use of high-speed tool steels and, as demonstrated at work, are good machines for modern manufacturing or general shop use. A planer and a shaper of good design and strongly built are also shown. The radial drilling machines shown by the same company are of good design and well built; they are also well balanced, as shown by the absence of vibration

when working at high speeds; the speed changes are readily made and the tapping attachment is very good.

Gould and Eberhart exhibit a shaper of excellent design and workmanship adapted for heavy work. The arrangement for changing the length and position of stroke is very good. The motor that drives it has two speeds brought about by sliding the armature through the field of the motor which reduces the number of change wheels required in the gear box. The same firm shows a special gear cutter which cuts two blanks at the same time; this is a strong, well built machine with several features that should be of interest.

In the extensive exhibit of products made by the Crane Co. is a motor-driven pipe-threading machine having two unusual attachments—a quick centering rear chuck and compressed air cutting-off tools. The whole machine is well designed and strongly constructed, and on account of the two unusual devices referred to is of interest to those specializing in pipe work and fittings. This machine is made by the Crane Co. for its own establishments.

The Landis Tool Co. exhibits grinding machines of both universal and special application. The several machines are of high-class design, massive in character and fitted to produce a wide range of work. The excellent quality of their work shows the care displayed in the building of the machines and the arrangement of the exhibit shows the wide and varied application of these machines in the mechanic arts.

requirements of the engineer for tools to produce anything within the compass of mechanics.

California being an extensive fruit growing state, much of that product must be shipped to other states and foreign countries either in wooden boxes or in tin cans and the machinery required to make these containers is of great interest. At the Exposition this class of machinery is well represented and merits a careful study by those interested in automatic machinery.

The William S. Doig Co. are pioneers in the manufacture of box making machines. Their exhibit contains a complete set of machines of wide range and application for labor sav-

FIG. 6 UNIVERSAL HOLLOW HEXAGON TURRET LATHE EXHIBITED BY WARNER AND SWASEY CO.

FIG. 5 UNIVERSAL EFFICIENCY TESTING MACHINE. TINIUS OLSEN TESTING MACHINE CO.'S EXHIBIT

There are a number of other metal cutting and shaping machines that attract attention in the Palace of Machinery and in the other buildings of this great Exposition; the engineer will discover them in places where he would never think of looking for such things, but on close inspection he will find that they are in some way connected with other things that belong in the place where he finds them. While the display of machine tools is, for reasons already explained, by no means complete, there is enough to dispel any anxiety in regard to the ability of the tool makers to meet all the

ing in the making of boxes. A clever device shown in this exhibit is a machine for fastening two or more pieces of wood together edge to edge. On this machine a number of reels contain corrugated steel ribbons sharp on one edge; if the pieces to be fastened together are long enough to require, say, four fastenings then there are four reels. The strips to be fastened together are drawn in at one end and discharged at the other. The corrugated ribbons are drawn in at one side at right angles to the seam and are cut off in lengths of about $1\frac{1}{2}$ in. and driven into the wood across the seam making a solid joint. This machinery enables strips of any width to be combined to make sides and ends, bottoms and tops of boxes, and saves much lumber that would otherwise be wasted. One machine with two boys will work up 4000 to 5000 feet of lumber in a day.

At the George D. Parker exhibit two box making machines are shown, both new in design. One of these, the orange box machine, has now obtained a wide use in California. It is automatic and makes an orange box in four movements. Another machine which has just been perfected after seven years' experimenting is shown. This completes a box at one stroke or revolution. The ends and sides are pushed up from below by a ram to the proper place while the bottom is pushed in from the back of the machine; the nailing mechanism acts simultaneously on the bottom and sides, while a ram pushes the finished box out of the way of the material

coming up for the next box. This universal machine is highly ingenious in design, entirely automatic in operation, of large capacity and has great economic value.

At the Max Ans Machine Co.'s exhibit is a complete set of can making machinery, arranged in the order usually occupied in a large can making establishment and being a complete outfit for making sanitary and open-top cans. Much ingenuity and good workmanship is displayed in this company's exhibit.

In the E. W. Bliss Co.'s exhibit is a very complete operating exhibit of power metal working machinery illustrative of the high degree of perfection to which this class of machinery has attained. The sanitary can making equipment is almost entirely automatic. The design of the different presses and carriers shows great mechanical ability; the auto-

that some of these machines are arranged to remind the operator of his omission should he neglect to do his part. This demonstration is very interesting and instructive.

At the exhibit of the Carborundum Co. in the Palace of Machinery is shown an exceedingly high class exhibit of unusual educational value, extensive application of product, and instructive demonstration. The product of this company has revolutionized certain methods of manufacture, lowered costs and increased output. The application of the cutting wheels, cylinders, and discs extends from the cutting of the hardest crystals to the buffing of leather and cloth.

Illustrative of cutting metals by a flame cutter there are several exhibits of the oxy-acetylene cutting and welding equipments. The best exhibit is that of the Davis-Bourmonville Co. in the Palace of Manufacturers as it shows a complete oxy-acetylene equipment including the apparatus for producing oxygen.

The fact that the Pacific Coast is a good market for saws, especially wood cutting saws, brought some good exhibits of that class of cutting tool to the Exposition, the most notable being the exhibit of Henry Disston and Sons, Inc. This firm shows a splendid collection of saws both for wood and metal cutting. The new forms of metal cutting saws with inserted teeth show the most advanced practice, the teeth being made of the newest grade of tool steel for high speed cutting in hard metals.

As he works his way through the Palace of Machinery, the mechanical engineer, if he be at all interested in the shaping of sheet metal, will stand for a while at the exhibit of the Dreis and Krump Manufacturing Co., who show a line of very well thought out brakes for bending metal plates. Three machines are shown, two being for light work, such as cornices or pilasters, adapted to all classes of straight line work, producing sheet metal boxes with right angle corners with great rapidity, and one for heavy steel plate, powerful in character and capable of bending to sharp angles plates $\frac{3}{8}$ in. thick and 12 ft. in length, this latter is a very original machine with well designed and strongly constructed steel working parts.

The Geometric Tool Co. in the Palace of Varied Industries exhibits tools for cutting external and internal threads, interesting on account of the fine and accurate workmanship and ingenious design displayed. The head for external threads opens automatically as soon as the length of thread for which it is set has been cut. For internal threads, the taps automatically collapse at the points for which they have been set. In each case, when the thread is finished the chasers do not return over the threads on the reversing of the tool. These tools can be used in any screw machine or turret lathe and show a decided advance in tools of everyday use.

The exhibit of the Hydraulic Press Manufacturing Co. is an extensive display of presses including pumps, valves, etc., for the manufacture of cider, olive oil, etc., and for filtering the same. There are shown also presses for bending or straightening metal bars, pressing car wheels on to axles and other similar lines of work.

Among small tools are those shown by the Henry G. Thompson and Sons Co. in the Palace of Manufacturers, whose exhibit consists of an interesting line of hack, power, and jig saws for cutting metals, and also some very clever tool holders.

FIG. 7 CYLINDER PLANNER EXHIBITED BY MORTON MFG. CO.

matic actions are perfect in operation, displaying fine construction and accurate workmanship. The individual presses with semi-automatic attachments for the manufacture of various types of metal boxes and cans and the automatic threading machines show the same fine workmanship and precision of operation of the automatic working parts. To this equipment is attached an ingenious and effective can testing apparatus which charges each can with 40 lb. air pressure and passes it under water, immediately showing a bubble if there is a leak; this testing is continuous and its speed equals that of the machine delivering the cans.

Also in the line of automatic machines, at the U. S. Army Ordnance Department exhibit is found a set of cartridge-making machines in operation; this comprises a very interesting set of machines that show the result of the long process of perfecting required in machines for delicate operations. To such an extent has this perfecting been carried out

The requirements of modern civilization have opened up many and varied fields for the engineer to cultivate for the good of humanity; this is very forcefully illustrated in the matter of food preservation and today there are large establishments devoted to the production of refrigerating machinery. There are four exhibits of refrigerating machinery at the Exposition that merit attention. Two of these are in the Palace of Food Products, one in the Horticultural Palace, and one in the Manufactures building.

The Larsen Ice Machine Co. has a very fine and interesting exhibit consisting of a complete plant for the freezing, storing, and hardening of ice cream, the daily capacity of the plant shown being 400 gal. The freezer cylinders and agitator are of German silver made without a seam, insuring perfect cleanliness.

Near this exhibit is that of the York Manufacturing Co.,

ingenious combination of reciprocating and tossing action by which the material is screened and conveyed at the same time, designed especially for moving and segregating hot ores, bolts, rivets, ashes, slag, etc.

The exhibit of lubricating oils made by the Union Oil Co. of California shows real achievement in petroleum technology and the company deserves great credit for its scientific development of lubricants from California crude oils. As petroleum specialists, this company has succeeded in developing oils suitable for all classes of lubrication, as has also the Standard Oil Co., which has shown great skill in the treatment of oils for the many and varied uses to which its product is applied.

To the engineer interested in the distribution systems of water works, the exhibit of the A. P. Smith Manufacturing Co. is one of great interest; this is a collection of water gate

FIG. 8 E. W. BLISS CO.'S AUTOMATIC CAN BODY MAKER. CAPACITY 150 CANS PER MINUTE

which is an exhibit of a complete refrigerating plant in operation, keeping cold several chambers throughout the building.

The exhibit of a complete refrigerating plant by the Vulcan Iron Works will be found very interesting. The refrigerating chambers are a part of the exhibit and, being of glass, show the splendid condition of the foods inside, there being no sign of dampness either on the inside of the glass insulation or on the contained meats, butter, cheese, etc.

The remaining exhibit of refrigerating machinery is by the Automatic Refrigerating Co. and is the only complete automatically controlled refrigerating plant on exhibition. The automatic control is a decided step in advance on new ground; it automatically stops the machine when the temperature in the refrigerator chamber reaches a point one degree below the temperature for which the machine is set and starts it again when the temperature is one degree above that point.

There are many other engineering exhibits in the Palaces of Machinery, Transportation, and Manufactures. Among those worthy of mention are the Dodge Manufacturing Co.'s exhibit of general power transmission machinery and accessories, which includes a good example of the Dodge system of rope drives. There is also the Zimer vibrating screen, an

valves, fire hydrants, water works machines and appliances. The most interesting feature is the exhibit of appliances used for placing a gate valve into a line of main pipe while the latter is under pressure.

The economical handling of materials in the shop is illustrated in the working exhibit of the Shepard Electric Crane and Hoist Co. This consists of electric power cranes and hoists for use from one or two overhead supports; also an electric winch, monorail track, and electric controllers and switches especially adapted for hoisting apparatus.

The General Electric Co. shows a complete self-propelled electric truck on which is mounted an electric crane; this is demonstrated in operation and is an attractive and instructive exhibit.

The correct measurement of the quantities of liquids during their transmission through pipes has always been an interesting problem, and at the Exposition are two exhibits, that of the Neptune Meter Co. and that of the National Meter Co., illustrating apparatus for this purpose.

The Neptune Meter Co. shows a very complete and well arranged collection of various types of meters designed to measure and record different liquids in various units and quantities.

A special form of the compound meter known as the "Protectus" is shown; this is of new design and contains in combination a disc meter, a turbine meter, and a "Control Orifice Tube" with an automatic check valve at the delivery end of the tube. This valve is operated by excess pressure in the tube when the flow from the discharge pipe of the compound meter exceeds 50 per cent of the capacity of the disc meter. The opening of the check valve acts mechanically to close the outlet valve of the disc meter and stop its action and open wide the passage through the orifice tube and the turbine meter. The turbine meter is proportioned to measure 25 per cent of the flow through the orifice tube and to register the combined flow of itself and the orifice tube. A special adaptation of the disc meter is shown in an apparatus for measuring and recording a predetermined quantity of liquid and automatically stopping the meter and the flow when that quantity has passed the meter.

Among others a meter of the turbine type named "Gem"

or heart-shaped cams with the face of the cam working on rollers to produce the motion for the pump ram or bracket. The motion transmitted to two or more pump rods may be so arranged as to give a non-pulsating constant discharge of water or other liquid. The surfaces of the cams are hardened as well as the rollers; they are both generous in size and little wear need take place.

The Layne and Bowler Corporation exhibits a turbine pump especially adapted to deep wells. Its special feature lies in the pump chamber being suspended from its upper end, as are the rotating parts. The shaft rotates inside a central pipe in which it has bearings at intervals, lubricated with oil or clear water injected at the top of the pipe; the shaft bearings are thus protected from contact with dirty water. The rotating parts are carried on roller bearings at the upper end of the shaft, and for heavy pressures these are supplemented by oil pressure applied between one or more pairs of discs.

The Krogh Manufacturing Company exhibits a variety of centrifugal, turbine, and plunger pumps for various uses, which are of good design. Among these are a vertical centrifugal mine sinking pump, cornish pumps, jack head pumps, multi-stage mine station pumps, single-stage motor driven horizontal centrifugal pumps, multi-stage high pressure turbine pumps, and a long double-suction centrifugal pump with a capacity of 30,000 gal. per minute. Each rotating disc fixed to the shaft is enclosed within a close fitting bronze ring which has free lateral movement. This is a well-designed pump marking progress in a class of machinery that has been in a stationary condition for some time past.

The American Well Works has an exhibit consisting of a large variety of centrifugal, turbine, and deep well plunger pumps, of good design.

Closely connected with pumps are pipes, valves, and fittings. These are found in great variety and of all dimensions in the Crane Co.'s exhibit, some of the main features of which are: One 72-in. wedge water gate in operation worked by a hydraulic lift and weighing 56,000 lb.; one 36-in. wedge water gate in operation worked by a motor; a complete line of steel water gates from 2 in. to 18 in.

There are many other exhibits that should have been mentioned if space permitted. In the Palace of Mines there is much that is interesting and new. This branch of engineering coupled with the advance in chemistry and metallurgy has made great progress in recent years and much of that progress can be traced in the exhibits in this building.

In the Palace of Transportation, the progress in that field of engineering can be traced through all its stages. In one corner is found an interesting old pioneer with the wagon in which he crossed the continent 65 years ago and from that point of beginning can be followed the progress in transportation upon to the present day, when 60 miles an hour can be made on our improved highways with almost the comfort of a railroad coach.

From the great exhibit of the Westinghouse Co. in the Palace of Transportation as a center, wherever one turns new wonders of mechanical genius continually arrest attention, and the skill that has conquered the land, the sea, and the air, all help to raise the engineer's estimate of the worth and dignity of the profession to which he belongs.

FIG. 9 REFRIGERATING PLANT EXHIBITED BY THE AUTOMATIC REFRIGERATING CO.

is shown; this is adapted only to the measurement of large and rapid flows and is used either alone or in combination with one of the oscillating piston type called "Empire," to form the "Empire Compound." In this arrangement the passage through the "Empire" is always open while that through the "Gem" is controlled by an automatic differential check valve which opens under the difference of pressure produced by a large flow through the "Empire" meter. Of special interest is an apparatus having the name of "Premier" to be placed in 30-in. water mains. It consists of one large and one small venturi tube in parallel relation.

Both these exhibits of meters are of great interest to the engineering profession, which is sufficient excuse for giving a somewhat lengthy description of them.

At the Exposition there is a large amount of pumping machinery for all the varied purposes for which pumps are used. The Luitwieler Pumping Engine Co. has an exhibit consisting of Luitwieler pumps of two different types adapted to surface, deep well and hydraulic service. The special feature is the method of driving. In place of the usual crank shaft operating through connecting rods there are eccentric

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

Among the problems of power generation which still await solution is that of the gas turbine. Holzwarth, it is true, built a gas turbine rated at over 1000 h.p. more than three years ago, but it has never been placed on the market commercially and its efficiency as claimed by Professor Stodola appears to be quite low. Of late, papers have stated that a large amount of work has been done on the gas turbine by the Brown-Boveri Company, which is said to have organized a special department for this work which is there carried on with a considerable amount of secrecy. Nothing concerning it has been reported in the regular trade papers, but from the newspaper reports it appears that the Brown-Boveri Company, like many other experimenters with gas turbines, had considerable trouble on account of the rapid wear of the turbine blades. In this month's Survey, an abstract is given of an article by Alfred Walter, on Gas Turbines, in which the author makes several statements of considerable interest. In the first place, he claims that the explosion type of gas turbine is limited in its possible development and that it is the constant pressure type that is likely to give the final solution. Further, he expresses a belief that the gas turbine will finally be developed along lines somewhat similar to those of the steam turbine, viz., that multiple wheels will be adopted for the gas turbine also. As a continuous process of flow does not appear feasible practically in the case of a gas turbine, the writer recommends a process composed of elements occupying long periods of time. He describes a design of gas turbine on rather novel lines, in which there are three chambers, two of which are working continually, while the third is in the state of cooling.

THIS MONTH'S ARTICLES

The Diesel engine propelled ship, *Pacific*, with its power plant and electrical equipment, is described. The article contains some data showing the growing adoption of the Diesel engines for ocean ship propulsion.

The next article compares the Diesel engine with the suction producer gas engine for ship propulsion, and shows that at certain prices for anthracite and oil, the suction producer gas engine may prove to be more economical than the Diesel engine.

F. Hoffmann presents data on the maximum contents of hydrocarbons in producer gas and among other things, gives a table showing the average output of gas from the most important German types of gas coals.

P. Ludwik describes an investigation into the properties of metals at higher temperatures; for steel and wrought iron up to 1300 deg. cent. This article is of interest, as comparatively little information has been published on the variation of strength of metals in these regions of temperature.

A communication from the Institution for Testing Materials of the Royal Technical High School at Stuttgart, is devoted to the investigation of the brittleness of wrought iron, produced by the heating of compressed materials. It is of particular interest to boiler engineers, as it affects the strength of the notched boiler plates. (The notching may come from knocking off scale.)

The question of the saving of fuel on locomotives by the use of feed water preheating and the differences in effectiveness of various types of preheaters, as well as the field of application for preheaters, is carefully considered in an article abstracted from a German periodical. In the same section are described locomotive superheaters using smoke tubes of small diameter.

Interesting statistical information on the increase in safety of boiler operation in Prussia is reported and illustrated by curves. The article shows that the number of explosions due to various causes is gradually decreasing and moreover, while, for example, the number of accidents due to careless attendance has increased during the last few years, the number of explosions due to this cause has decreased, which would indicate that boilers are being so built that they can withstand a certain amount of carelessness in handling without actually going to pieces.

A steamship is described having turbo-electric propulsion, the system at the stern end consisting of a Ljungström turbine, with a total ratio of transmission between turbine and propeller as 1:133.3.

In connection with the utilization of coke as fuel under boilers, the Belani grate is described, with its provision for igniting the coke before it reaches the traveling grate.

Of the papers presented before the American Institute of Mining Engineers are reported those on the manufacture and test of silica brick for the by-product coke oven, on mine pumping and a conveyor belt calculating chart.

From the Journal of the American Society of Naval Engineers are reported papers on the heat losses in steam engineering, methods of testing safety valves at the United States Naval Experiment Station and on land storage of bituminous coal. The latter paper is of particular interest as it raises grave doubts as to the effective ability of the United States Navy coal storage plants to safely store the amounts of coal for which they have been designed.

William Rodger, in a paper before the Canadian Railway Club, discusses the relative advantages of using hydraulic presses as compared with power presses for the manufacture of cartridges and shells.

Data on interesting tests of butterfly valves on locks in the Black Warrior region in Alabama, are abstracted from the Professional Memoirs of the Corps of Engineers, United States Army.

FOREIGN REVIEW

Internal-Combustion Engineering

DIESEL ENGINE PROPELLED SHIP, *Pacific*, W. Kaemmerer.

Description of the Diesel engine propelled ship, *Pacific*, and its power plant.

The Burmeister & Wain Company, of Copenhagen, are the largest builders of Diesel engine ships. They now have under construction ten ships of 10,000 tons each, three of 9000 tons, six of 5000 tons, one of 7000 tons and three of 6500 tons.

The *Pacific* made its trial runs last December and was at once taken over by the owners, who proposed to use it for

the La Platte and Pacific Ocean business. It is 110 m. (360 ft.) long over all, 15.5 m. (50.8 ft.) beam, 7 m. (22.9 ft.) draught and has a capacity of 6500 tons. The engine room is very short and is located in the stern end of the ship. The ship has three decks and five loading hatches, each served by two electrically driven winches.

The power plant consists of two directly reversible 4-stroke cycle Diesel engines having each six cylinders, 540 mm. (21.2 in.) bore and 730 mm. (28.7 in.) stroke, delivering together 2000 i.h.p. Contrary to the practice of Diesel engine building in German shipyards, in this case the engines are enclosed and provided with lubrication under pressure. The arrangement, however, is such that the cylinders are left easily accessible. They are cast in blocks of three and although they are open on the bottom, the piston rods pass through stuffing boxes, the purpose of which is to prevent dirt from the cylinders falling into the lubricating oil. The pistons are comparatively short and are equipped with self-tightening rings. Each cylinder cover has built into it a fuel valve, suction, exhaust, starting and safety valves, the starting valve being water cooled. Each engine has six fuel pumps,—one for each cylinder,—all driven from a common shaft. The pumps take the fuel by suction from two tanks located in the engine room, containing enough fuel for a run of 24 hours. They are filled every twelve hours, which gives the oil a chance to deposit some of the impurities which it contains. The cross-heads of the engines have guides on one side and in all other respects are similar to those on steam engine driven ships.

In addition to the main engines, there are two auxiliary Diesel engines, likewise 4-stroke cycle, each driving a dynamo and compressor, and each delivering 200 i.h.p. at 225 r.p.m. For the usual requirements of the ship one engine is sufficient, the other serving merely as an auxiliary unit. Each compressor delivers air at from 20 to 25 atmospheres. This air is stored in two steel tanks, from which it is taken to start the engines. Each of the main engines has in addition a high pressure compressor which takes the air from the auxiliary compressor at 20 to 25 atmospheres and compresses it to 60 atmospheres. Each of the high pressure compressors is large enough to deliver the entire air blast for the two main engines. All the pumps (two centrifugal pumps for the cooling water, two centrifugal pumps for the oil under pressure, two charging pumps, and two pumps for drinking and service water) are driven separately by electric motors, the centrifugal pumps directly and the other pumps through gear transmissions.

When loading and unloading the ship, the compressors are uncoupled from the auxiliary Diesel engines which then serve to drive the dynamos exclusively. One dynamo is in most cases sufficient to deliver all the current required for the winches and the other auxiliary machinery and lighting purposes. When the winches are not at work and the operation of a large Diesel engine would be economical, the lighting current is supplied by a small 110-volt dynamo, driven by an ordinary 2-stroke cycle crude oil engine. This auxiliary dynamo also delivers current to drive a small high pressure air compressor furnishing compressed air for starting the auxiliary Diesel engines; this compressed air is stored in a separate tank which can be fully charged in two hours.

For heating purposes, there is installed in the rear end of the engine room a vertical boiler with oil firing. The total weight of the engine plant, with its entire equipment, auxil-

iary engines, pipes and repair parts, is 440 tons. The fuel which has to be carried for a return trip to South America is less than 700 tons, and therefore, as compared with the steamship, it can carry about 1000 tons more cargo. During test runs, the *Pacific*, with an output of 2032.5 i.h.p., has developed a speed of 11.41 knots. (*Das Motorschiff "Pacific," gebaut von Burmeister & Wain A.-G., Maschinen- und Schiffbau-Anstalt in Kopenhagen*, W. Kaemmerer, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 34, p. 677, August 21, 1915, 5 pp., 10 figs., d.)

OIL AND SUCTION PRODUCER GAS ENGINES FOR SHIP PROPULSION

The article gives comparative data on the economy of operation of Diesel engines on one hand and producer gas engines on the other, as applied to ship propulsion.

The author believes that the producer gas engine cannot be dismissed as being uneconomical, even though it has not yet been brought up to its full perfection. He cites the following comparative data of operation of the two types of power plants (In the original article the figures are apparently mis-printed and an attempt has been made in the abstract to give what would appear to be the correct figures. The doubtful figures of the original article are enclosed in straight brackets side by side with those which would seem to be the correct figures).

It is assumed that a marine Diesel engine consumes about 0.2 liter (0.21 qt.) of oil per h.p.-hr. Under these conditions, 100,000 h.p., at a price of 5 pfennigs per liter, will cost approximately 1000 marks (say \$240). A suction gas engine of the same output, consuming 0.454 kg. (say 10 lb.) of anthracite per h.p.-hr. will burn, with anthracite at 24 marks per metric ton, approximately 1100 marks per 100,000 h.p.-hr. In order that such an engine should work as economically as a Diesel engine, the price of anthracite must go down to about 22 marks per ton. In this case, therefore, and in all others where Diesel engines are used having a fuel consumption as low as 0.2 liter per h.p.-hr., the suction engine is economically less efficient than the Diesel engine. If, however, the price of the Diesel engine oil goes up to say 6 pfennigs per liter, or 60 marks (say \$14.85) per metric ton (2200 lb.) then the cost of fuel with the Diesel engine rises substantially to about 1250 marks per 100,000 h.p.-hr., while if the suction gas engine uses anthracite at 26 marks per ton, the cost of producing 100,000 h.p.-hr. goes up to only 1180 marks [1080 marks].

The above data just referred to can be considered as average prices for the two fuels and show a slight advantage in favor of the suction gas engines. It must, however, be borne in mind that the price both for oil and for anthracite is often higher. If now the suction engine be compared with a gasoline engine, the advantages in favor of the former will be still more pronounced. A gasoline engine consumes approximately 0.33 liter of fuel per h.p.-hr. and therefore 100,000 h.p.-hr. will cost about 2000 marks as compared with 1180 marks [1080 marks] for the suction gas engine of the same output.

The author states that the oil engine in its various forms is so well entrenched in its position that it is doubtful if in the near future the suction gas engine will find more favor in marine circles than it does to-day, but when this happens, the suction gas engine will be found fully efficient for marine propulsion (*Untersuchungen zwischen Schiffslä-*

und Sauggasmotoren, *Polytechnische Rundschau*, supplement to *Elektrotechnische Rundschau*, vol. 32, no. 30/31, August 4, 1915, 2 pp., 3 figs., *cc*).

MAXIMUM CONTENTS OF HYDROCARBONS IN PRODUCER GAS, F. Hoffmann.

The author believes that in many cases the results of analysis of producer gas with respect to the contents of hydrocarbons are subject to doubt, and he thinks that it might be of interest to establish the limits within which the contents of hydrocarbons in producer gas can vary. With respect to producer gas made from bituminous coal, it can be established without particular difficulty.

It appears that this question has never yet been fully investigated. The author discusses first the generation of producer gas, and divides its constituents into the following four classes:

1. Steam.
2. Products of dry distillation, consisting mainly of tars, hydrocarbons and hydrogen, with a small addition of carbon monoxide and carbon dioxide.
3. Products of gasification, mainly carbon monoxide with carbon dioxide and hydrogen from steam supplied into the producer.
4. Nitrogen which comes mainly from the air supplied for the purposes of gasification and only to a very slight extent from nitrogen in the coal (under certain conditions, such as leaks in the piping, some air may be found in the producer gas, shown during the analysis by the presence of oxygen in amounts larger than traces).

A good basis for the determination of the highest contents of the products of distillation in bituminous coal gas producers is given by the data obtained in the manufacture of illuminating gas. It must, however, be remembered that computation based on average figures never strictly coincides with data actually obtained, especially as the conditions of dry distillation present in the manufacture of illuminating gas are not unessentially different from those in the manufacture of producer gas. With our present insufficient knowledge of the processes occurring in dry distillation of coal, we must be very careful how data of experience with pure dry distillation is transferred to dry distillation in the gas producer, particularly in view of the fact that the dry distillation in the producer occurs at a lower temperature (especially when much steam is added) than in illuminating gas retorts.

As a basis for calculation of the amounts of products of dry distillation, the author uses, chiefly, data of experiments obtained in the laboratory at Karlsruhe on test distillation of fifty of the most important kinds of German gas coals (published in *Journal für Gasbeleuchtung*, 1913-1914).

In analyzing the figures of the output, the contents in illuminating gas of nitrogen and various compounds of nitrogen and sulphur have been neglected in order to simplify the computations. This is permissible with respect to nitrogen because the nitrogen in the gas is due mainly to the unavoidable presence of air in the gasification chamber. On the other hand, K. Bunte has shown that of the nitrogen present in the coal, approximately 60 per cent passed into coke 20 per cent, as free gas, into the illuminating gas; 15 per cent into ammonia; 3 per cent into cyanogen and 2 per cent into tar, so that it may be assumed that when coal is gasified in a producer, practically 80 per cent of the

nitrogen present in the coal will be found as gas in the producer gas. This is the figure which the author uses in his computation.

Table 1 gives the average output of gas of the most important German types of gas coals [referred to pure coal and the elementary composition of the gaseous products of dry distillation obtained from 100 kg. (220 lb.) of pure coal]. This table shows that the gases of distillation as obtained from 100 kg. of pure coal are essentially as follows: 9.346 kg. Carbon + 3.685 kg. Hydrogen + 3.423 kg. Oxygen.

The author then proceeds to discuss the output and composition of the tar formed in dry distillation and comes to the conclusion that if nitrogen and sulphur be neglected the following formula would hold good: in 100 kg. of tar there are 92.5 kg. Carbon + 4.4 kg. Hydrogen + 2.2 kg. Oxygen. (*Die Maximalgehalte des Generatorgases an Kohlenwasser-*

GAS TURBINE, Alfred Walter.

Discussion of the question of the gas turbine.

The author believes that the entire problem is handled in a wrong manner and especially that insufficient attention is paid in the attempts to design a gas turbine to the designs of steam turbine engineering. He objects, for example, to the rather general assumption that in a gas turbine only an impulse wheel should be used and that the waste heat of the exhaust gases should be utilized in a regenerator.

While he believes that in general the tendency in the development of the gas turbine is towards the ideal Carnot

cycle, he points out that the reciprocating steam engine as a periodical machine and the turbine as a continuously acting machine, go along entirely different roads toward the common goal,—the Carnot idea.

With particular reference to the gas turbine, the author believes that a great obstacle to its development lies in the assumption of the theoretical superiority of the explosion type of turbine over the constant pressure turbine. One cannot help objecting to placing a blade wheel in front of a periodical mechanism (explosion chamber with many valves), even though theory says that that is the right way to do. The author asks why one could not get some sort of an arrangement which would allow a continuous or at least a long period flow of gases of combustion to the turbine wheel. As regards the explosion turbine, he believes that there is a limit to its possible development. Its first successes were due to the fact that it represented the most primitive combination of an explosion motor and a turbine. Actually, however, in order to secure continuity of work, chamber on chamber have to be added with numberless valves and rods, and if so, what becomes of the simple gas turbine sought for?

The author attaches particular importance to a clear understanding of the following four points:

a. Since a pure continuous constant pressure process is practically impossible, processes should be selected which

combustion chamber continuously under constant pressure and the air of combustion and the cooling air are admitted by the same pipe. The fact that the pressure in the combustion chamber is approximately constant makes it possible to use the normal type of turbine, in addition to which provision is made for a strong cooling of the entire turbine.

The large amount of air which has to be used in connection with this process appears to be a disadvantage at first, but the author claims to be able to show that this is what makes the process possible at efficiencies which are not excessively unfavorable. Fig. 1 shows the diagrammatic construction of the turbine. There are assumed to be three combustion chambers, *a*, of which two are working and one is in the state of being cooled. Through the pipe *b* the fuel is admitted into the combustion chamber and through pipe *c*, the air. In the combustion chamber is found further the ignition device *d* (hot bulb or electric). In all the three chambers the same pressure prevails. All the three chambers are freely connected with the turbine space *f*, by expansion nozzles *g*. Into the chamber which is being cooled at the time there flows from the compressor, air through pipe *ed*; this air takes up the residues of combustion and expands in the nozzle *g*, delivering some work to the turbine so that a certain part of the energy consumed by the compressor is again recovered in the turbine.

The expansion produces a powerful cooling of the air in addition to which the air constantly takes hot water from the walls of the turbine wheels, which constitutes a further addition to the work done by the air. In this light, the minus in heat loss of gases of combustion through cooling really appears as a plus. After the completion of the cooling period, the automatically operated fuel valve *b* opens and the fuel is blown into the combustion chamber through pipe *b*, mixes there with air and is ignited.

A proper shape of combustion chamber adapted to the kind of fuel used will produce either rapid or slow combustion. The mixture is expanded through the nozzle *g* and does its work in the turbine. Owing to the fact that in the chamber *a*, there prevails an approximately constant pressure, it is possible to build the turbine with more than one wheel and to obtain in this way conditions of work and efficiencies approximating those used in steam turbine construction. This has the further advantage that the cooling of the entire turbine is made possible, which depends on the conditions of flow in the turbine.

The author claims for this construction the advantage of having a small number of parts the motion of which has to be controlled, high thermodynamic and mechanical efficiency, low gas velocities and speeds and efficient utilization of the cooling air.

(*Gedanken und Anregungen zur Frage der Gasturbine*, Alfred Walter, *Zeits. für das gesamte Turbinenwesen*, vol. 12, no. 23, p. 265, August 20, 1915, article not finished, *id.*)

Materials of Construction

PROPERTIES OF METALS AT HIGHER TEMPERATURES.

P. Ludwik

The article is devoted to an investigation of the properties of metals at higher temperatures. The following metals have been investigated: aluminum, lead, cadmium, wrought iron, cast steel, copper, magnesium, brass, nickel, zinc and tin.

All the metals were taken in wire form, commercial brands

WALTER GAS TURBINE. FIG. 1.

permit the greatest amount of continuity, such, as for example, the constant pressure process having long periods in which the period of combustion per chamber must be drawn out as long as possible with the temperatures obtaining under possible cooling.

- b.* A powerful cooler should be installed both for the combustion chambers and the entire turbine, without, however, excessive consumption of fuel and loss of heat.
- c.* An attempt should be made to use a simple impulse wheel or normal turbine device (multiple wheel and drum, impulse and reaction), which afford the best results with respect to efficiencies, mechanical strength and wear.
- d.* The question should be considered as to how the exhaust heat may be utilized in other ways than by means of a regenerator.

In addition to the above, the author describes a novel process of his own, in which the usual constant pressure method is used, but the working cycle occurs, though intermittently, still at long periods. The air is admitted to the

of the highest purity obtainable. The length of the test bars was approximately 60 cm. (23.6 in.). The bars were heated in an electric furnace, the temperature being measured by various thermo-elements. In all tensile tests, the following values were determined:

The original cross-section of bar $f_0 = \frac{\pi d_0^2}{4}$

The test temperature

The highest load obtained P

The cross-section of bar f

The cross-section at the place of rupture f_u .

Then

$K_t = \frac{P}{f_u}$ is tensile strength

$\sigma = \frac{P}{f}$ is tensile stress

$100 \frac{f_0 - f_u}{f_u}$ contraction, in per cent

$100 \frac{f_0 - f}{f_0}$ uniform elongation, in per cent.

Contraction and corresponding elongation give at the same time the limiting values of elongation on rupture of pieces of various lengths.

As regards the various metals investigated, the following remarks are of interest:

Aluminum. With increasing temperature, the hardness and strength steadily decrease, while the ductility and malleability steadily increase. At 500 to 600 deg. cent., the latter was so great that aluminum, like lead, could be drawn to a fine point.

Wrought Iron. While the iron tested was not chemically pure, it was of very low carbon content (the chemical analysis indicated 0.06 per cent carbon, 0.47 manganese, 0.037 phosphorus and traces of silicon). The curves in Figs. 2A and B make clearly apparent the well-known fact that at the so-called blue heat (about 250 to 300 deg.) there is a higher strength with greater brittleness. At 600 deg. the ductility is at its maximum. Of interest also is the rise of tensile strength at about 800 deg.

Cast Steel. Virtually it was hard wrought iron close to the steel limit. As in the case of wrought iron, the maximum of strength and brittleness was reached at about 250 deg. At about 600 deg., likewise, the ductility is at its maximum.

Copper. A decrease of strength with increase of temperature is continuous down close to the melting point. The contraction of area materially decreases between 200 and 600 deg., increases at about 800 deg. and starts to decrease again above it.

Brass. Strength and ductility decrease as a rule with increase of temperature.

As regards the metals in general, the variation of strength with temperature falls into two main classes. The pure metals, with the exception of iron and nickel, show a fairly constant decrease of strength with temperature, while iron and nickel, as well as most of the alloys, show pronounced variations within certain characteristic regions of temperature which the author ascribes to allotropic transformations occurring at those temperatures.

The author discusses in considerable detail the question

of variation of specific heat of metals with temperature and brings out data on the relation between the heats of melting and volume moduli. An interesting part of the article is that devoted to the consideration of the relation between the atomic volumes of metals on the one hand and their hardness and strength on the other. (*Festigkeitseigenschaften und Molekularhomologie der Metalle bei höheren Temperaturen*, P. Lindwik, *Zeit. des Vereines deutscher Ingenieure*, vol. 59, no. 33, p. 657, August 14, 1915, 8 pp., 9 figs., et.c.)

BRITTLENESS OF WROUGHT IRON AS A CONSEQUENCE OF HEATING COMPRESSED MATERIAL, R. BAUMANN

The article is a communication from the Institution for Testing Materials of the Royal Technical High School at Stuttgart.

The tests carried out have been prompted by the observation that boiler plate, which has been deeply notched during the process of knocking off boiler scale, proved to be very brittle, which may have been due to the action of compression

FIG. 2 A. K_t , "TENSILE STRENGTH" OF METALS AT VARIOUS TEMPERATURES. B. CONTRACTION OF AREA OF METALS AT VARIOUS TEMPERATURES.

together with subsequent heating to a sufficiently high temperature. Tests have also shown that other kinds of boiler material developed after cooling a considerable amount of brittleness if previously compressed and then heated to a yellow color. This may afford an explanation for many cases of rupture of boiler plates and the formation of cracks, as com-

pression and subsequent heating are phenomena of frequent occurrence.

As a rule the presence of deep notches or compression alone are not enough to produce material brittleness. To bring this about, it is necessary that a corresponding amount of heat be applied, and that, further, the constitution of the material be of a certain definite nature. Often test bars made from the same plate do not become brittle to the same extent. The old rule, that unnecessary notches should be avoided, etc., has not been disregarded by the present tests.

The author describes a process which has been applied for testing boiler plate and established the inferior quality of some plates, which had passed the usual tests satisfactorily, but developed cracks in actual service. This test consists in pressing a cylinder of hardened steel 10 mm. (0.39 in.) in diameter against the face of the plate normally to the skin due to rolling and at an angle of 60 deg. to the axis of the bar:

Railway Engineering

SAVING OF FUEL ON LOCOMOTIVES BY THE USE OF FEEDWATER PREHEATING. Strahl.

Careful consideration of data on the saving in coal and increase of output of locomotives by means of preheating the feed water (compare Table 2), indicates that the use of exhaust steam preheaters gave a saving of 13 to 19 per cent (in accordance with the type of construction and load on the boiler), as compared with similar locomotives without preheaters. But when a waste gas preheater was installed in addition to an exhaust steam preheater, the saving rose to 19 to 27 per cent, or from 6 to 8 per cent more, which is quite a material increase in economy. Actually during test runs on the Prussian State railways, of wet steam and superheated steam locomotives on which exhaust steam superheaters were subsequently installed, the saving of coal within the

loading with a pressure of 2500 to 3000 kg. per cm. of length of bar subjected to pressure (13,750 to 16,500 lb. per in.), the thickness of the test bar being 15 mm., and then heating the bar to a yellow color and bending it after cooling in water.

The tests were carried out on plates 20 mm. thick (0.78 in.) having a tensile strength of 4100 kg./sq. cm. (say 58,000 lb. per sq. in.). The behavior of plates of greater thickness and higher tensile strength has not been established by the present tests.

The tests have clearly established the influence of direction of rolling, a fact which has to be taken into consideration in performing notch shock tests. (*Sprödigkeit von Flusseisen als eine Folge der Erwärmmung gequetschten Materials*, Richard Baumann, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 31, p. 628, July 31, 1915, 4 pp., 12 figs. *ed.*)

above limits was established beyond dispute; often it rose to over 20 per cent.

While the saving in coal on locomotives with exhaust steam preheaters in average operations was actually found to be considerably below these figures, hardly exceeding 10 to 11 per cent, this was due to the fact that either the increased capacity of the locomotive could not be utilized beyond a certain limit, or during runs with closed throttle or during periods of standing at stations, the preheating was not available, which affected the results even though feeding the boiler during such periods was avoided as carefully as possible. In this respect, the situation with the waste gas preheater is much more favorable, since the waste gases may be used for preheating the feed water even when the throttle is closed.

The average saving of fuel through preheating by exhaust

steam is the greater the less frequently the throttle has to be closed during the operation of the locomotive. Hence, the economical advantages of feed water preheating on locomotives operating express trains and fast freight trains which make long runs without stopping, is of greater importance than in local passenger trains and ordinary freight train service, and is greater in regular service than on switching locomotives. It is quite possible, and sometimes happens, that the economical advantages of exhaust steam preheating may become entirely insignificant, especially on locomotives which even without preheaters have a sufficient output and

the ratios of dimensions are the same as on the superheated steam locomotives of the Prussian State Railways, or 20 to 25 per cent with a smaller ratio of heating surface to grate surface. In good accord with this is the information given by Trevithick, managing director of the Egyptian State Railroads, concerning runs of their superheated steam locomotive, No. 712. The feed water was preheated by an exhaust steam and a waste gas preheater connected in series, to a temperature of 145 deg. cent. With this locomotive a saving of 20 per cent, as compared with two superheated steam locomotives without preheaters, was secured, and with another

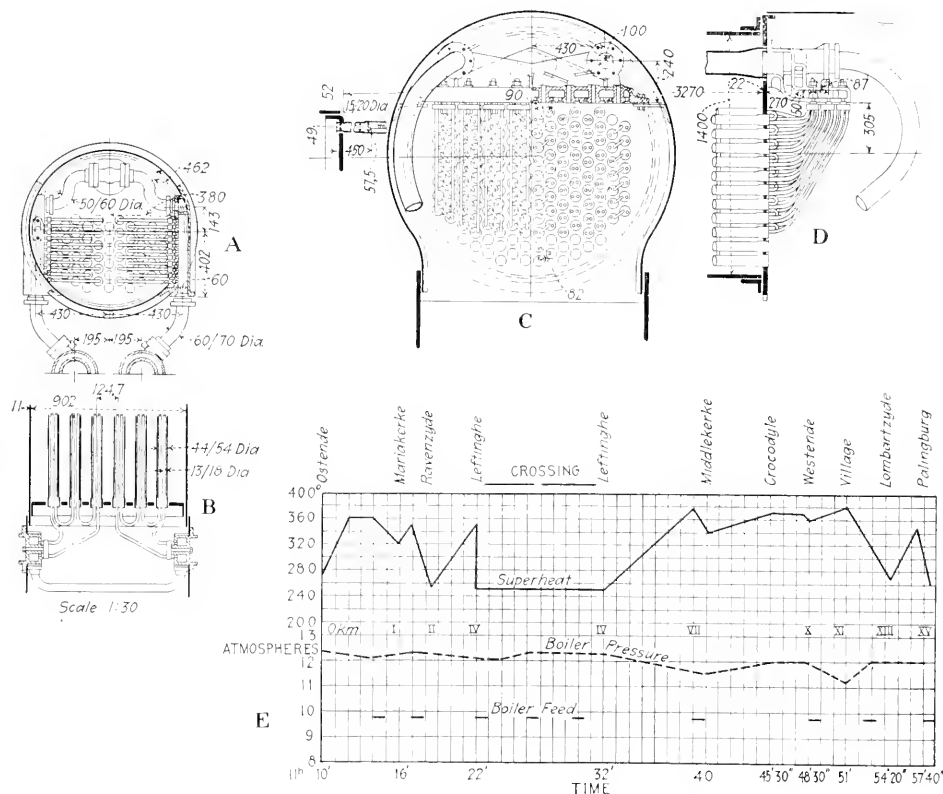

FIG. 3. LOCOMOTIVE SUPERHEATERS WITH TUBES OF SMALL DIAMETER

leave but little to be desired with respect to steam generation. It is advisable to install preheaters on locomotives which need them; e.g., when the boilers are already overloaded.

In order to best utilize the increased output of the boiler, it is advisable on new locomotives on which the feed water preheater is installed, to increase the size of the steam cylinders, since otherwise increases of load are possible only to a limited extent. If, however, the size of the cylinders is adapted to the increased output of the boilers, excellent results can be obtained.

The saving of coal by feed water preheating on superheated steam locomotives with exhaust steam and waste gas preheating, amounts to approximately 19 to 24 per cent if

similar locomotive, No. 711, a saving of even 27 per cent was obtained, as compared with 29 other locomotives. The latter saving is considered by Trevithick to be too high, because Locomotive No. 711 was placed on test runs when new and was therefore in first-class condition. (*Die Kohlenersparniss oder grössere Leistungsfähigkeit der Lokomotiven durch Vorwärmung des Speisewassers, Strahl, Annalen für Gewerbe und Bauwesen*, vol. 77, no. 2 914 and 3/915, July 15 and August 1, 1915, *pc.*)

SMALL-SMOKE-TUBE SUPERHEATERS FOR LOCOMOTIVES, Metzlin.

Description of recent developments in the design of Schmidt superheaters, in particular for locomotives.

The modern type differs from the older type in that the large smoke tubes have been eliminated and the entire boiler filled with tubes of diameter only slightly larger than that of fire tubes hitherto used. The space saved in this manner has been largely, if not exclusively, occupied by superheater elements. This type of superheater construction has several advantages which have been established in practice, as follows:

They give a more rapid and higher superheating than the old smoke tube superheater, and therefore are particularly convenient for street railway service and local lines where many stops have to be made. With the same boiler diameter, the new type of superheater, which is called the "small-smoke-tube" superheater, can utilize about 30 per cent more heating space than the old superheater with large fire tubes could do.

The use of smoke tubes of moderate diameter has above all the great advantages that the walls of the tubes are not exposed to the high stresses which may occur with large smoke tubes. Smooth tubes, 50 to 70 mm. (1.96 to 2.75 in.) in diameter in long boilers, are apt to sag somewhat during the runs of the locomotive, due to their own weight and vibration, so that they cannot offer any great resistance to increase of length on account of the heating. On the other hand, larger tubes of 125 to 133 mm. (4.9 to 5.2 in.) in diameter, often with lengths of 5 to 6 m. (16.4 to 19.69 ft.), do not bend at all and therefore do not yield in any way with rises of temperature. The manipulation of the small-smoke-tubes is no more difficult in locomotive shops than that of larger tubes. The Netherland Tramway Company, in Herenveen, have had 30 tender locomotives with fire tubes 50 mm. (1.9 in.) and superheater tubes 11 mm. (0.42 in.) in diameter, in use for three years without experiencing any serious trouble.

The superheater elements of the small tube superheaters consist usually of 4 or 6 tube bunches, which in their turn consist of two or three tubes. The first arrangement of the steam collector chamber used was such that the chamber was located vertically, parallel to the exhaust blast tube in such a manner that the superheated steam space was in front and the wet steam space behind. This arrangement has the advantage as it is very simple. An arrangement which is considered to be very good is shown in Figs. 3A and B, representing the superheater for a street railway locomotive of the Mass-Bnurt railway in Holland. There, each of the steam collector chambers, located to the right and to the left, is divided in two parts for the superheated steam and wet steam. This arrangement permits a very good design of the superheater elements, the two superheated steam collectors being inter-connected by a pipe 40 to 50 mm. (1.5 to 1.9 in.) in diameter. The arrangement shown in Figs. C and D is widely used on the Belgian, Hungarian and Italian railways.

As to the results gained with small-smoke-tube superheaters, an idea may be obtained from the chart in Fig. E, representing curves established by a test of a C-type street railway locomotive on the Belgian local railways. Special attention is called here to the fact that temperatures of 340 to 380 deg. could have been maintained for a comparatively long time. (*Kleinrauchröhren-Überhitzer für Lokomotiven*, Metzeltin, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 32, p. 645, August 7, 1915, 6 pp., 21 figs. d.)

Steam Engineering

CONCERNING THE INCREASE IN SAFETY OF BOILER OPERATION IN PRUSSIA, B. Hilliger.

The author attempts to prove that the number of boiler accidents in Prussia has decreased during the last few years. He divides all accidents into three groups,—explosions,

FIG. 4. EXPLOSIONS (PER UNIT OF 10,000 BOILERS) CAUSED BY (A) DEFECTS IN MATERIAL AND WORKMANSHIP, AND (B) DEFECTIVE ATTENDANCE.

accidents which lead to the boiler being put out of operation and various defects producing accidents. In the main, disturbances in operation are produced by one of the following four causes: *first*, defects in material and workmanship; *second*, piping, connections and auxiliary apparatus; *third*, attendance, and *fourth*, operating conditions. He reports his data in the form of tables and curves, some of which are here reproduced. Fig. 4A shows the number of boiler ex-

plosions caused by imperfections in material and workmanship, referred, for purposes of comparison in various years, to a unit of 10,000 boilers. The great jump in the number of boiler explosions between 1894 and 1897 is due to the fact that during that time a different definition of boiler explosion was used by the statistical office.

Under the class of explosions due to boiler piping, connections and auxiliary apparatus, are handled all accidents due to jammed or overloaded safety valves, clogged or incorrect manometers or finally, defective feed water apparatus; also accidents due to the clogging of passages leading to the water gages and incorrect indication of water level by the gages. The curve shown indicates that the number of accidents reported as due to this cause is comparatively small and varies widely in different years, which, under these conditions, may be due to accidental causes.

The number of accidents due to lack of proper attendance appears to be comparatively large. Explosions in these cases are very often due to lack of water in the boiler, which can be traced to the carelessness of the fireman. Fig. B indicates the gradual falling off in the number of explosions. (The reasons for an unusual increase of explosions as shown by the curve for the periods 1894 to 1897 has been explained above.) In this connection, the author points out a curious phenomenon,—namely, that statistics indicate that the number of accidents due to careless attendance on boilers has increased in the last few years, while the number of explosions due to this cause, has decreased. Since the majority of accidents due to this cause are produced by low water level, it would appear that the boilers are being so built that they can better withstand trouble of this nature. Table 7 offers an opportunity of judging the tendencies in explosions and accidents in boiler plants by giving a comparison between what took place from 1885 and 1889 on one hand, and from 1909 to 1913 on the other. The same data are represented by curves in the original article. (*Untersuchungen über die Zunahme der Sicherheit der Dampfkesselbetriebe in Preussen*, B. Hülliger, *Zeits. für das Vereinig. deutscher Ingenieur*, vol. 59, no. 34, p. 681, August 21, 1915, 7 pp., 10 figs., s.)

TABLE 3. COMPARATIVE DATA SHOWING THE VARIATION IN THE NUMBER OF BOILER ACCIDENTS IN THE LAST 15 YEARS

SWEDISH SHIP WITH TURBO-ELECTRIC PROPULSION

The Swedish coaster, Mjölnir, was built by the Lindholmens Verksted, in Göttingburg, and has a displacement of 2250 tons, a speed of 11 knots, is 68.6 m (225 ft.) long, with 10.97 m (36 ft.) beam and 4.5 m (14.7 ft.) draught. The propeller shaft, which carries a single screw, is driven by two synchronous motors, arranged to transmit their power through a gear transmission with two pinions, each motor operating

on one pinion. This transmission reduces the speed from 900 r.p.m. on the motor shaft to 90 r.p.m. on the propeller shaft, the total power delivered to the propeller shaft at 90 r.p.m. being about 900 h.p. The current is generated by two 500 volt, 100 cycle alternating current dynamos, having an output of about 400 kw. each, at 6000 r.p.m. These data indicate that the ratio of transmission between turbine and propeller is extremely high; in fact it is 1:133.3, and this permits the obtaining of a comparatively low steam consumption, notwithstanding the moderate size of the power unit. Although no complete data of any test of the engine have been published, it is expected that the steam consumption will be about 4.5 kg. (9.0 lb.) per shaft h.p.-hr. In runs made previous to delivery simultaneously with the sister ship, Meiner, driven by triple expansion steam engines, it was found that the new ship had a coal consumption 35 per cent

FIG. 5. BELANI GRATE FOR BURNING COKE UNDER BOILERS

less than the other steamer. (*Ein neuer turbo-elektrischer Schiffsantrieb*, F. Zeits. für das gesamte Turbinenwesen, vol. 12, no. 23, p. 274, August 20, 1915, 1 p., d.)

COKE AS FUEL UNDER BOILERS, II. Markgraf

In a previous issue of *The Journal* (September, 1915, p. 558) reference has been made to efforts in Germany to supplement the lack of the usual coal fuel by the utilization of coke, and to various experiences in this connection. The present article covers approximately the same ground in a more detailed way, and brings up some comparatively new data.

First, the author points out that, contrary to the prevailing impression, the temperature of combustion coke is lower rather than higher than that of coal. He shows that in order to attain the same temperature in the furnace, the combustion of coke must be much more complete than that of coal. Judging temperature by the color of the flame with the naked eye is apt to lead to errors. Coke flame is brighter than coal flame but that does not prove that its temperature is higher, because the coal flame is rendered somewhat darker by the presence of decomposing hydrocarbons and carbon particles resulting from this decomposition.

The greatest trouble was experienced in attempts to burn coke on traveling grates which had been designed mainly to

take care of fuels rich in gas, but not those containing little or practically no gas, such as coke. There must be found therefore some other way of igniting the fuel coming into the furnace than by the use of a zone of incandescence produced by a glowing arch. This seems to have been accomplished by engineer Belani, of Essen, Germany. In his arrangement shown in Fig. 5, there is provided a sort of pre-ignition where the coke is ignited before it reaches the traveling grate, which makes the action of the arch entirely superfluous. The pre-igniting device which supersedes the usual fuel supply hopper and has about the same dimensions as the latter, consists of a funnel shaped shaft, lined with fire bricks, equipped at the front with an inclined grate and connected on the other side by a passage with the fire chamber of the boiler. Under this connecting passage there is provided a slide valve regulating the height of fall of the fuel. The device is operated as follows:

First, the furnace is filled as far as the grate bars with coke which has been previously brought up to a state of incandescence. Then the entire hopper shaft is filled with fresh coke. As a result of the chimney draft, air is drawn in between the grate bars and through the glowing layer of coke, while the gases of combustion generated there go through the passage above referred to, directly into the boiler furnace. As the parts of coke lying on the traveling grate in a state of incandescence are drawn away, fresh coke is supplied from the hoppers.

Tests of this apparatus are said to have given satisfactory results. (*Die Verwendung von Koks zur Dampferzeugung*, Dr.-Ing. H. Markgraf, *Stahl und Eisen*, vol. 35, no. 33, p. 847, August 19, 1915, 6 pp., 2 figs. o.)

MANUFACTURE AND TESTS OF SILICA BRICK FOR THE BY-PRODUCT COKE OVEN, Kenneth Seaver

The paper describes methods of manufacture and testing for the determination of effects of burning of silica brick.

American practice in the manufacture of silica brick is far above that of any other country. As the author states, in some instances, European manufacturers have refused to credit the possibility of making to such specifications as are common in this country until the actual completed shapes were shipped for inspection.

By silica brick, the author understands only a brick having a silica content of 94 per cent or more and made usually from quartzite with a small percentage of lime as a binder. He discusses in detail the materials used, such as Pennsylvania, Wisconsin and Alabama quartzite, and its various stages of manufacture, such as quarrying, grinding, molding and burning, and, in the latter connection, gives data concerning the effect of burning on composition, expansion and physical strength of the brick. He comes to the conclusion

that while by quick burning, brick may be easily expanded to double or treble the normal amount, this is not conducive to the production of sound brick. In general, he believes that the present good commercial practice carries the results of the quartz-cristobalite inversion to the greatest degree economically possible. He reports also a series of tests having for their primary object the determination in how far the inversion from quartz to cristobalite has progressed under various conditions. (14 pp., 3 figs. ep.)

MINE PUMPING, Charles Legrand

This paper is a discussion of the questions of mine pumping, such as the selection of proper pumps under various conditions, the design of the pump, especially its piston and packing, and the selection of the driving plant and transmission. A number of tests are reported in tabular form on

FIG. 6 CONVEYOR BELT CALCULATING CHART

several sizes of steam and electric pumps, as well as on air lifts. With the latter, in the best test for 200 ft., 1680 gal. per min. of water were delivered. (6 pp. e.)

CONVEYOR-BELT CALCULATING CHART, J. D. Mooney and D. L. Darnell

The chart shown in Fig. 6 has been drawn as a means to determine quickly the correct number of plies of conveyor belts operating under specific conditions. The calculations are based on the average safe strength (factor of safety of 15) of the various standard rubber conveyor belts. The calculations assume a maximum load condition, i.e., the belt is considered as carrying the greatest load that it will handle without spillage at ordinary belt speeds, which produces the most economical operating conditions and maximum tension in the belt. The chart represents graphically the formula

$$p = kgW(L + 10H)$$

where p = the correct number of piles; k = constant de-

pending on the type of drive; g = the weight in pounds per cu. ft. of material handled; W = width of the belt in inches; L = length of the belt in feet, approximately twice the center distance; H = the difference in elevation between the head and tail pulleys in feet.

For a simple drive, with a bare pulley, $k = 1/250000$; for a simple drive with a rubber-lagged pulley, $k = 1/300000$; for a tandem drive with bare pulleys, $k = 1/375000$ and for a tandem drive with rubber-lagged pulleys, $k = 1/455000$.

The chart is drawn for a simple drive with a bare pulley and therefore the number of plies obtained from the chart should be multiplied by the factor 0.83 or 5/6 for simple lagged drive; a factor of 0.67 or 2/3 for tandem bare and a factor of 0.55 or 11/20 for tandem lagged drive.

The length factor $f = L + 10H$, represented on the chart by the lines 500, 600, etc. is a developed factor equal to the sum of the length of the belt and 10 times the difference in elevation between the head and tail pulleys.

To find the correct number of plies for a conveyor belt, knowing the width, length, difference in elevation between the head and tail ends and the kind of material to be handled, start from the width given at the top of the chart and move downward until this line intersects the line corresponding to the proper length factor; then move either right or left until the line corresponding to the given material is met; then move down again to the scale of plies where the next largest figure will give the desired correct number.

For example, to find the correct number of plies for a conveyor belt 36 in. wide and 300 ft. long, with 20 ft. difference in elevation, handling sand and gravel, follow the 500 length line; then follow to the right until the "sand and gravel line" is intersected; then down to the ply scale where the ply will be found to be 7. (3 pp., 1 fig., μ .)

HEAT LOSSES IN STEAM TRANSMISSION, W. L. Cathcart.

General discussion of heat losses in steam transmission, both for superheated and saturated steam.

The question of radiation and conduction is discussed from the point of view of the Stefan-Boltzmann law of radiation (in which the radiation of a black body is proportional to the fourth power of its absolute temperature).

For the external conduction, the author establishes formulae based on the general method of Mollier, the transfer of heat from one fluid to another, through an intervening solid, being divided into three stages: External conduction from the first fluid (steam) to the solid (pipe metal); internal conduction through the latter; and external conduction from the pipe to the second fluid (air). From the data obtained in Eberle's tests, the author calls attention to the fact that there is a marked difference between the values of k_1 (coefficient of external conductivity of steam to plate) for superheated and saturated steams. Saturated steam cannot lose heat without partial condensation and hence there

is not only a film of condensate adhering to the interior surface of the pipe, but probably the column of moving steam has also a thin casing of condensate. The usual formulae do not consider these insulating films, since the heat transfer through them is too complex a process. With highly superheated steam, these conditions do not prevail, since the pipe, if properly protected, is hotter than the corresponding temperature of saturated steam.

The author reports fully the Péclet formulae for heat losses, both by radiation and by conduction. The heat losses of saturated steam in uncovered pipes are discussed in detail and a table is given where there are assembled data of 19 of the principal tests of uncovered pipes containing saturated steam. In this table are given the total losses as computed by Péclet's formula, and it is shown that the average correction to be applied to the latter is 0.3. The necessity for the correction is explained by the fact that the Péclet results were derived from laboratory experiments on apparatus of limited size, while under practical conditions, the condensate method involves possible errors.

The heat losses of covered pipes are likewise discussed. The article is of interest as giving a very clear presentation of a very important subject, combining data from the best sources (26 pp., gt).

METHOD OF TESTING SAFETY VALVES AT THE U. S. NAVAL EXPERIMENT STATION, L. R. Ford.

The article describes the method of testing safety valves at the United States Naval Experiment Station and in particular, the testing of the safety valves on the U. S. S. Nevada.

The requirements for safety valves are briefly reported and the experimental arrangement described in detail. The tests of springs are described in particular. The maximum fibre stress in the spring occurs at the middle of the inside edge of section of the spring coil and is made up of the four component stresses due to torsion, direct shear, bending and direct compression. The effect of the last two is sufficiently slight to be neglected. The first two produce a maximum shearing fibre stress, which is calculated for a valve lift of 0.100 in. by the following formula:

$$S = \frac{9Q \cos \theta R}{2bh^2} + \frac{Q \cos \theta}{A}$$

where Q = load on spring in pounds; R = the mean radius of the coil measured from the axis of the spring to the center of gravity of sections in inches; θ = the angle of inclination of coil to a plane perpendicular to the axis of the coil. The shearing modulus of the spring material is calculated for a valve lift of 0.100 in. by the following formula

$$d = \frac{Q \cos^2 \theta R^2 L}{CJG} + \frac{Q \cos^2 \theta L}{AG}$$

in which d = axial deflection per coil in inches

Q = load on spring in pounds

R = mean radius of coil in inches by measurement

p = pitch of coils in inches

$L = (p - d)^2 + (2\pi R)^2$ = length of one free coil in inches actively opposing the compression of the spring

$$\cos \theta = \frac{2\pi R}{L}$$

C = St. Venant's constant for the resistance to torsion of bars of nearly square section

$A = h \times \frac{B+b}{2}$ = area of section in square inches

h = altitude of trapezoidal section in inches

B = larger base in inches

b = smaller base in inches

$J = \frac{h}{48} (B^3 + B^2b + Bb^2 + b^3) + \frac{h^3}{36} \left(\frac{B^2 + 4Bb + b^2}{B+b} \right)$
= polar moment of inertia of trapezoidal section in inches

G = shearing modulus of elasticity in pounds per square inch (12 pp., 4 fig., *ed*).

LAND STORAGE OF BITUMINOUS COAL; THE EVER PRESENT FACTOR OF SPONTANEOUS COMBUSTION; AND A FEW FACTS AND SUGGESTIONS IN CONNECTION WITH SAME.
Geo. R. Crapo.

The writing of this article was prompted by the fact that from November 15, 1914, to February 20, 1915, a series of fires of a spontaneous nature, sixteen in all, took place in the coaling plant under the charge of the writer, at the Naval Station, Key West, Fla. From what appears in this connection, it seems that this matter of spontaneous ignition of coal is of far greater importance than is generally realized.

The plant at the Naval Station, Key West, Fla., consists of two steel sheds, one 150 x 100 x 20 ft. at the caves, and the other 250 x 75 x 20 ft. at the caves. From the above dimensions, using 42.5 as the average density of coal, it is seen that the plant was built for the purpose of storing 15,883 tons of coal within ready reach of the conveyors for rapidity of handling.

The best authorities contend, however, that coal cannot be safely stored at a depth of over 14 ft. and even at that depth, a careful watch must be kept constantly on it. This means that the plant, designed to store nearly 16,000 tons of coal in such manner that rapid discharging and loading of vessels can be effected, can be used only for the storage of 11,000 tons; it again means that if in case of war, the plant is called upon to work to full capacity and the coal is urgently needed, it would either be too hot to place safely in the vessel's bunkers, or the prolonged and continual heating would have so exhausted its calorific qualities as to render it poor steaming coal. It appears, therefore, that something is radically wrong; either the adopted system of storage or our lack of information on a subject of this importance.

The author discusses the conditions contributing to the ignition of coal. He calls attention to two very simple tests, showing in advance whether or not the coal in question can be safely stored. One of these tests is given by Professor Fisher, of Göttingen, as follows:

Coals which absorb bromine rapidly are most liable to spontaneous ignition. Shake one grain of finely ground coal with 20 cc. of a half normal solution of bromine for a period of five minutes. If the smell of the bromine has then disappeared, the coal is likely to oxidize rapidly and is not a safe one to store.

Professor Lewes gives the following test:

Coal that gains more than 2 per cent in weight when heated to 250 deg. Fahr. for three hours, is a very dangerous coal to store.

The author discusses in detail the supposed causes of ignition. He comes to the conclusion that an open shed with just enough superstructure to support the overhead mechanical devices for use in the handling of the coal, is far superior and safer than the closed type. He does not believe that coal exposed in open air for, say one year, will lose all of its calorific properties. The Florida East Coast Railway and several shipping and commercial concerns keep varying quantities of coal at Key West in the open, often for considerably over one year, and the coal gives good average results for steaming purposes.

The overhead conveyor system, with the apron perhaps from 45 to 60 ft. above the floor of the shed, is very bad practice, *first*, because coal in its fall generates additional heat and before this heat can escape, another bucketful is dropped upon the first, and *second*, the coal falling from this height, breaks a large percentage of the lumps and creates more fine coal dust, which, in itself, is a dangerous element.

Too great dependence should not be placed on the temperature readings (which the author, however, strongly recommends to be made), as it very frequently happens that that portion of coal which fires first is not the portion which indicates the highest thermometer reading; often the portion first heated may get a draft of air in consequence of the heating and the heat then move and deposit elsewhere.

A promiscuous use of water in extinguishing fires in a coal pile is of practically no value. A coal pile will often heat almost to the point of coking and then subside, but if water is used at that stage, the coking will take place at once and coal will be lost which otherwise might be saved (12 pp., 1 fig., *gp*).

CANADIAN RAILWAY CLUB

HYDRAULIC PRESSES VERSUS POWER PRESSES FOR THE MANUFACTURE OF CARTRIDGES AND SHELLS, Wm. Rodger.

The author discusses the question whether hydraulic or power presses are the more economical and efficient for the manufacture of cartridges and shells. He considers four types of presses: Steam Pump Presses, Hydraulic Presses, Motor Driven Power Presses and Direct Steam Presses.

Steam Pump Presses. Boilers are required to generate steam for the pumps and the pumps must be large enough to supply the water at the pressure and velocity to keep the accumulator up when the presses are in operation. A receiving tank, having direct connection with the water main, is also absolutely essential. With this type of press economy in steam power can be obtained by the use of a trip valve, operated automatically, which cuts off the steam when the press is not in operation. It is good policy to make the pumps 25 per cent larger than is actually required, as at times the pump is liable to give out with overload on the press.

Hydraulic Presses. In the case of a hydraulic press, the position of the presses should be determined relative to the pump and to the accumulator in order that the pipes may be arranged to eliminate right-angle bends, for the purpose of preventing sudden shocks and bursting of pipes, which would materially retard the output. In the manufacture of cartridges and shells, the writer is convinced that the use of an accumulator is indispensable; for example, should a triplex

pump, which gives a more even flow of water pressure, be used, a certain loss of energy would manifest itself; consequently, the pressure at the press would be oscillating in character, but this would be obviated by the use of an accumulator. It is often advisable to operate a press or other hydraulic tool direct from a pump without the use of any interposed accumulator, but for this special work it is essential that the accumulator be employed to give the desired results, as without its use any pressure from 1500 lb. per sq. in. upwards could be obtained without any means of regulation of the pressure.

A motor driven pump consists of a hydraulic plant operated by steam supplied to an electrical generating set, which in its turn supplies current to the motor driving the power pump; the electrical generating outfit being a high speed

DESCRIPTION OF TESTS OF BUTTERFLY VALVES ON LOCKS IN THE BLACK WARRIOR REGION, IN ALABAMA.

On the system of locks on the Warrior and Tombigbee Rivers, all the culverts except two are controlled by butterfly valves, either in pairs or in sets of three. These valves are set with their axes vertical, and are operated by hand through a simple worm and sector. On the whole, they have given satisfaction, but certain difficulties in their operation have led to the tests described in the article, and proper changes followed as a result.

The first eight locks built on the Warrior and Tombigbee

FIG. 7. BUTTERFLY VALVE EXPERIMENTS.

engine and having a short cut-off, it will use less steam and consume less fuel.

Motor Driven Power Presses. In the opinion of the writer the best method of placing the motor is to drive onto a countershaft, which, although it necessitates a special self-starting rheostat, permits the press to be driven by a smaller motor as the load or torque of the motor is overcome by the countershaft.

Direct Steam Presses. The direct steam press is not suitable for shell and cartridge making, as it is not possible to attain the required pressure per square inch at the back of the piston (11 pp., p.).

CORPS OF ENGINEERS, UNITED STATES ARMY

Professional Memoirs, vol. 7, no. 35, September-October 1915, Washington Barracks, D. C.

The Diesel Engine, Capt. John M. Wright
Butterfly Valve Experiments, Lieut. Col. Charles Keller (abstracted)

Rivers were equipped with pairs of butterfly valves, 6 ft. 0 in. high, 2 ft. 10 1/2 in. wide, operated from the tops of the walls. At three of these locks, each valve was set in an independent frame and operated as a single unit by a simple lever keyed to the top of the shaft. At the other five locks, the valves were operated in pairs by a worm and quadrant gear. With three valves thus connected to a worm and gear device, it was found that the total moment which one man could exert was 58,020 in.-lb., or 19,340 in.-lb. to each vertical shaft, which was not enough with heads of over 10 ft. to permit a single operator to open a set of three valves to normal position.

The difficulty of operating three valves keyed to a single hand wheel was attributed to two causes: First, when two or more valves are operated simultaneously, the water deflected from the first or upstream valve, when partly open, comes in contact with and tends to close the second valve; the stream deflected from the latter offers a similar resistance

to the opening of the valve next down stream. *Second*, the valve divides this stream moving into the valve opening and the portion of the current down stream of the valve is deflected by the valve body. The eddy motion thus caused may produce a reverse pressure on the immoving or down stream side of the back plate of the valve near the culvert floor, this also tending to close the valve.

Various deflection plates or partitions were installed and in August, 1911, a series of tests was made to ascertain the effect of these various arrangements of deflection plates applied to butterfly valves of the kind above described. The tests were made on a quarter side valve carefully built of steel.

A comparison of the curves of the first diagram of Fig. 7 for a lower valve with those for an upper valve (B and C) shows a material difference in the curves, which is due to the absence of backwater in the upper culvert. This again shows that the sheet of water entering when the valve is "cracked" is deflected free of the inturning half of the lift by the second deflection plate, Fig. B, which causes the valve to slam open. As a result of this test, it was decided to add to all butterfly valves then in service, in addition to the 3-in. deflection plate originally provided, a second plate 5 in. wide, screwed to the back of each valve with horizontal angle of 45 deg. between them and with the outer edge 4 in. upstream from the center line of the back plate, as shown in "C," top Fig. 7. The additional deflection plate, combined with certain partitions between the valves, has made it possible for one operator to open to normal position the three valves of one side simultaneously and under full heads up to 21 ft. (4 pp., 4 plates, *et c.*)

UTAH SOCIETY OF ENGINEERS

Vol. 1, no. 8, August 1915, Salt Lake City, Utah.

THE RELATION OF STREAM GAGING TO THE SCIENCE OF HYDRAULICS. C. H. Pierce and R. W. Davenport

The article represents a general discussion of the modern tendencies in the development of the science of hydraulics as affected by the work done in stream gaging, especially in connection with various irrigation problems in the United States and also by the United States Geological Survey.

The author believes that methods for the measuring of discharge, such as the use of salt or other chemicals, or the use of a diaphragm in open channels of uniform cross-section, are likely to become increasingly valuable, but as with the use of the weir, they probably will not be universally applicable as means of measurement. The current meter is undoubtedly founded on the right principle and it is hardly conceivable that it will be superseded.

A study of the evolution of stream gaging shows the important part played by empirical developments together with scientific research, and it is even conceivable that in time the

same results might have been obtained through empirical processes alone. This fact is illustrated by some features of the present method of stream gaging. The observations of velocities at six-tenths and two-tenths of the depth have resulted from a large number of experiments, but it is now a well known fact that these methods are supported by the form of the vertical velocity of curve, which is that of the parabola; in fact, the author criticises somewhat the development of the present studies of stream gaging, in that possibly too much reliance has been placed on empirical methods and the advantages to be gained from scientific analyses have been given too little recognition.

Theoretical considerations embraced under the science of hydraulics, constantly appear as supplementary to the practical applications. For example, a thorough knowledge of Chézy's formula may often be of great practical use in analytical studies of stream flow data, although the field of direct application of the formula is limited.

The drainage investigations which have recently been undertaken in some of the Southern States for the purpose of reclaiming thousands of acres of rich agricultural lands afford an excellent illustration for the need of stream gaging of a high degree of precision. Many valuable experiments tending to increase the knowledge of hydraulic phenomena have been carried out in connection with irrigation work in the arid regions where, in some special investigations with comparatively small quantities of water, volumetric methods were used. In the work of the United States Reclamation Service, the science of stream gaging has been applied to a large number of problems, such as determination of friction losses in large size wood-stave pipe; values of the coefficient of roughness for different materials; proper coefficients to be used in computing discharge through gas; efficiency of pumps and turbines and economic size and cost of power plants for pumping water for irrigation.

The author comes to the general conclusion that a large amount of research is yet needed before hydraulics can become an exact accepted science, but the recent developments in stream gaging point to the possibility that this branch of hydraulics may in time reach a state of perfection such that all problems connected therewith may be solved with mathematical exactness and the term "probable error" be reduced to a rational quantity. (8 pp., 1 fig., *g.*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles in the Survey.

NECROLOGY

R. PAUL STOUT

R. Paul Stout was born at Bethlehem, Pa., in 1869. He was educated at a private school at Audenried, at the Hill School of Pottstown, and later at Lehigh University, from which he was graduated in 1891 with the degree of Mechanical Engineer. During vacation periods, he served as a machinist in the shops of the Janesville Iron Works.

His first position after graduation was that of mechanical engineer with the Lehigh & Wilkes-Barre Coal Company at Audenried. He entered the employ of the Bethlehem Steel Company as assistant superintendent of the armor plate department in 1894, when the armor for the United States battleships *Brooklyn*, *Oregon*, *New York* and *Iowa*, and the Russian ships *Petropavlovsk*, *Admiral Sinuivan*, *Admiral Oushakov* and *Rostislav*, and also the first large armor plate vault for the Philadelphia Savings Fund Society, was being manufactured by the company. During this time, too, face-hardened armor was first manufactured in this country and the best Harveyized armor in the world up to that period was developed at the Bethlehem plant.

In August, 1897, on the formation of the Bethlehem Company's ordnance department, Mr. Stout was transferred to that department and two years later he assumed charge of the development of the first piece of ordnance mechanism of its own design which the company sold. Under Engineer of Ordnance Lieut. Meigs, he had charge of all the experimental and development work in this department until September, 1910, when he himself was appointed Engineer of Ordnance, which position he held up to the time of his death. Within his period of service in this capacity, the company secured the largest naval ordnance order placed in this country, in the complete ordnance equipment and armor for the Argentine battleships *Moreno* and *Rivadavia*, and it was in the last two or three years that the company attained its present position in the manufacture of all kinds of ordnance and munitions.

Mr. Stout was elected to membership of the Society, member grade, in 1906. He was also a member of The Franklin Institute. He was killed on August 25 as the result of the accidental detonation of a high explosive shell.

JOHN CHARLES WILLIAM GRETH

John Charles William Greth was born in Buffalo, N. Y., in 1874. He attended the public schools of that city and was graduated from the Buffalo Central High School in 1893. In the same year he entered Cornell University and was graduated in 1897 with the degree of Mechanical Engineer. After graduation he began his engineering work by installing and operating for a few months a power plant at a summer resort on Lake Erie. From 1898 until 1902 he successively installed pumping machinery, designed special machinery, operated a power plant and installed and operated refrigerating and ice making plants.

In 1902, he entered the service of Wm. B. Seate & Sons Co., Pittsburgh, Pa., as manager of the water softening and purification department, and from that year until his death his time was devoted to the development of apparatus and methods for the softening and purification of water for all purposes.

Mr. Greth took out sixteen patents on improvements in water purifying apparatus, several of which embodied radical

features. He occupied a leading position in the field of water purification and his forceful presentation contributed very materially to the advancement of the science and application of water purification for industrial use.

Mr. Greth was the author of a number of articles on water purification published in the engineering press and he read several papers on the same subject before various engineering societies. He was recognized as an expert in water purification by engineers and chemists and his integrity gained for him a wide circle of friends.

He was a member of the American Society of Civil Engineers, the American Institute of Chemical Engineers, Engineers Society of Western Pennsylvania, and of the American Chemical Society.

He was elected a member of the Society in 1907. He died at Gibsonia, Pa., on August 7 after a short illness.

HERBERT GRAY TORREY

Herbert Gray Torrey was born in New York in 1839. He was educated in the College of the City of New York, from which he was graduated in 1860. He became the assistant of his father, John Torrey, who was the first chief assayer in the U. S. Assay Office in New York City, and he succeeded his father at the latter's death in 1873. He served as chief assayer until 1910, when he went into private practice, becoming president of H. G. Torrey and Co., assayers and metallurgists; he retired in 1912.

Mr. Torrey was also a consulting chemist, a specialist on alloys and a government expert in textile fabrics and an examiner of mines. He maintained a private metal shop at Stirling, N. J., manufacturing magnolia metal. He invented Torrey metal, an anti-friction alloy.

He was a member of the Society of the Cincinnati, the American Institute of Mining Engineers and The Franklin Institute. He became a life member of the Society in 1890. He died at his home at Stirling on August 29.

PERSONALS

Gilbert R. Haigh has recently become associated with A. D. Wilt, Jr., of the Wilt Twist Drill Company of Walkerville, Ontario, Canada, in drill manufacture and industrial engineering.

Carleton Wandel, formerly associated with the New York Central and Hudson River Railroad, West Albany, N. Y., has accepted a position with E. W. Bliss Company of Brooklyn, N. Y.

C. R. Cady has accepted a position with Smith, Hinchman and Grylls, Detroit, Mich., as industrial engineer. He was until recently affiliated with the Celfor Tool Company of Buchanan, Mich.

William J. Sweetser, until recently assistant professor of mechanical engineering at Case School of Applied Science, Cleveland, O., has been appointed professor of mechanical engineering at the University of Maine, Orono, Me.

Emile J. Bayle has resigned his position as general engineer of the American Beet Sugar Company, Denver, Colo., to accept the position of production manager for the Aluminum Castings Company, at their Detroit plant.

James A. Hall has resigned his position as draftsman with the Link-Belt Company, Philadelphia, Pa., to take up the assistant professorship in mechanical engineering at Brown University, Providence, R. I.

H. Owsen has severed his connection with the Standard

Steel Car Company, Butler, Pa., as assistant chief draftsman of the die department, and has accepted a position with the Carnegie Steel Company, Homestead, Pa.

William E. Moore has resigned his position with the West Penn Traction and Water Power Company Properties, Pittsburgh, Pa., as vice-president and general manager, and will open offices in Pittsburgh as consulting engineer.

Arthur F. Murray, formerly associated with the International Steam Pump Company, St. Paul, Minn., has become connected with The Blake and Knowles Steam Pump Works, East Cambridge, Mass., as equipment engineer.

M. William Ehrlich has severed his connections with Cole, Ives and Davidson, after two and one-half years of service, and has taken up the duties of editing *Electrical Engineering*, a monthly paper devoted to the field of electric practice, with headquarters in New York City.

Bart D. Thompson has become associated with the Curtiss Motor Company of Hammondsport, N. Y., as production manager. He was until recently foreman of machine shop of the National Twist Drill and Tool Company, Detroit, Mich.

William T. Clark has accepted a position with the Automatic Machine Products Company, Brooklyn, N. Y., as general manager. He was formerly connected with the Enterprise Manufacturing Company of Pennsylvania, Philadelphia, Pa., as manufacturing manager.

G. D. Bradshaw, steam engineer of the Cambria Steel Company, has tendered his resignation and on October 1 will enter business for himself at Pittsburgh under the firm name of Andrews-Bradshaw Company. Mr. Bradshaw has been in the Steam Engineering Dept. of the Cambria Steel Company for the past five years. Prior to that time, he was employed by the Indiana Steel Company at Gary for one year, and by the Illinois Steel Company of Chicago for five years.

R. S. Farr has been appointed instructor in mechanical drawing and design at the Towne Scientific School of the University of Pennsylvania, Philadelphia, Pa.

Frederick H. Moody has left for active service as an infantry captain, second in command of No. 4 company, 83rd Battalion, Canadian Expeditionary Force. He has been nine years in the Canadian Militia, five years in the ranks in the Engineers, and four years as a commissioned officer in the Queen's Own Rifles of Canada.

Louis J. Illmer Jr. has accepted a position as chief engineer of the Lake Heat Engine Company of Bridgeport, Conn., developing Mr. Simon Lake's inventions and ideas as applied to Diesel engines for submarine drives.

William F. Turnbull has been appointed instructor in mechanical drawing and design at the Towne Scientific School of the University of Pennsylvania, Philadelphia, Pa.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 18th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. In sending applications stamps should be enclosed for forwarding.

0244 Machine shop foreman between 25 and 35, capable of handling about 50 men. Experience with agricultural implement parts preferred. Salary \$110 to \$125. Location Pacific Coast.

0245 Storekeeper between 35 and 40, with at least three years' experience in charge of store department. Conscientious man required. \$125. Location Pacific Coast.

0246 In engineering department for young college graduate M.E. with one or two years' experience in shop practice or in time study. Salary according to qualifications. Location Maine.

0248 Large concern in Central New York State, manufacturing pumping machinery, has vacancies for technical graduates interested in taking student's course in shop and testing department. Compensation 25 cents per hour for 55 hour week. Work leads directly to sales department where advancement depends on ability shown. Reply by letter.

0249 Draftsman, machine tool worker, jigs, dies, etc. Some shop experience preferred. Give age, experience and salary expected. Location East Chicago, Ind.

0250 General electrician to take charge electrical department of cement plant. To be working foreman when necessary and superintend three electricians and two motor attendants. Repair, construction and transmission work necessary. Salary \$150. Location Southern States.

0251 Mechanical engineer experienced in designing and building special machinery for manufacture of paper goods and printing, to take charge of drafting room and large machine shop of 1000 machine capacity. Splendid opportunity for right man. Apply by letter, stating experience and expectations.

0253 Capable machine tool designer with 15 or 20 years' practical experience in shop and drawing room, to design lathes and turret machinery from 1500 to 4000 lb. Location New York State.

0255 A state university needs two competent instructors in mechanical engineering. Excellent practical and preferably teaching experience desired. One in machine design, other in mechanical engineering laboratory practice and steam engineering. Send full statement of training and experience, with list of references and recent photograph. Salaries according to qualifications. Location Central States.

0256 Designer and constructor of steam and centrifugal pumping machinery. Man who can take charge of department in small factory. \$35 to \$40 per week, with possibility of advancement. Location Michigan.

0259 Large casualty company has opening in its steam boiler and llywheal insurance department for special agent and solicitor. Insurance experience unnecessary and the company would be glad to receive applications from men with selling experience in mechanical lines and familiar with steam plant operation. \$100. Location New York.

0261 Two or three first class mechanical draftsmen, competent to lay out and develop plans in detail of wood and steel brake construction. Location Scranton, Pa.

0265 Thoroughly practical mechanic who has had considerable shop experience, and has executive ability. Prefer young man. Location Ohio.

0268 Designer of crushing, conveying, elevating and mining machinery. Salary \$40 per week. Location New York.

0269 Junior draftsman on same work as 0268. Salary \$25 per week. Location New York.

0270 Combustion engineer, with practical and technical experience with boilers, stokers and auxiliaries. Knowledge of boiler and refrigerator testing, power plant work. Give references and salary expected. Location New Jersey.

0271 Wanted, a mechanical engineer salesman, by firm with business in various parts of Spanish America, handling mining, agricultural, power plant and railway machinery. Must be a native of the U. S. and a graduate mechanical engineer with degree from a U. S. college or university. Not under 30 nor over 45. Ability to write specifications on pumps, steam power plant equipment and locomotives; successful experience as salesman; good address and appear-

ance essential. Must speak and write Spanish well. Apply by letter.

0274 General superintendent to develop machine factory; thoroughly practical and responsible and in position to systematize special automatic machines. Knowledge of paper products and German language essential. Salary according to qualifications. Location Hoboken, N. J. Apply through Society.

0277 Recent graduate with practical experience and adaptability for research work required as assistant to testing engineer. Salary \$80 to \$100 to start, depending upon ability and experience. Location New Jersey.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated in consecutive issues of the Bulletin. Names and records are kept on the office list three months, and at the end of such period if desired must be renewed.

J-269 Student member, 1915 Columbia University graduate M.E., desires a position in or around New York which offers an opportunity to start in the engineering profession. Salary to start secondary consideration.

J-270 Ordnance engineer, member, M.E. degree 1913, age 35, married, fourteen years' experience, five and one-half years in army ordnance department, three and one-half years captain of coast artillery, completed ordnance school of application, familiar with electrical machinery and gas engines, commended for management and also familiar with efficiency systems, desires administrative position in development of military manufactures.

J-271 Designer of automatic machinery and general engineering is open for position.

J-272 Member, graduate engineer, age 35, American, capable designer, practical foundry and shop man, experienced in modern production, methods and management, has had broad engineering experience in Europe and America as mechanic and executive in design and manufacture of engines, heavy machinery, machine tools, automatic machinery and light grade specialties, desires position as chief engineer, superintendent, manager or assistant. Location immaterial, salary commensurate with position.

J-273 Mechanical engineer, five years' practical experience in steam turbines, power plant equipment and layouts; also reinforced concrete and construction work. Future opportunity considered before salary. No preference to location. At present employed.

J-274 Member, technical graduate, age 34, experienced in editorial and publicity work, can write forcefully and with exceptional ability in attractive arrangement of copy, desires position as assistant to advertising manager.

J-275 Member, mechanical engineering graduate of Worcester Polytechnic Institute, age 26, two and one-half years' experience in engineering department of a large steel plant, wishes to make a change and become permanently connected with a New England company or firm where he can learn the business and become of value to it.

J-276 Graduate M.E., age 31, well posted on pumps and pumping machinery of all types, oil, gas and steam engines, drawing room and shop practice, sugar house work in Mexico and sales engineer in Brazil, desires permanent employment with reliable firm either in sales, office or shop. At present employed as salesman and expert on farm machinery.

J-277 Mechanical electrical engineer, age 32, married, with five and one-half years' experience on the design and installation of all kinds of factory equipment, and the practical application of the principles of scientific management, desires a change. First class man on time study standardization and systematizing. Salary \$2400.

J-278 Member, age 35, with an unusually thorough

experience in rubber mill engineering, including developments, reports, designs, specifications and contracts for buildings, power requirements and manufacturing equipment, desires position with consulting engineer or large rubber mill. Salary \$4000. At present employed.

J-279 Technical graduate, M.E., age 28, experienced in shop and drafting room, elevating and conveying machinery, desires position as draftsman or designer with good chance for advancement.

J-280 Junior member, Columbia graduate M.E., 1913, two years' experience in production and drafting department, desires position in New York with chance for advancement. At present employed.

J-281 Associate-member, age 33, with experience as sales engineer and in charge of sales in specified territory, of air compressors, refrigerating and pumping machinery, including layout and installing, desires position as local sales manager with headquarters in Chicago. Prefers to associate himself with manufacturer who is looking for a considerable increase in sales and needs a capable and conscientious representative to obtain such a result.

J-282 Associate-member, age 34, technical and practical training, specialized in manufacturing of cement, ten years' experience designing, building and operating crushing and cement plants, two years' selling experience, desires position as sales engineer with concern manufacturing machinery for cement and crushing plants, or accessories connected with the industry.

J-283 Member, age 32, married, who has held positions from shop errand boy to present position of general manager, wishes to become connected with large industry or undertaking; thoroughly acquainted with automobiles, has traveled extensively and has had charge of men for fifteen years. Would like to be assistant to general manager, but would consider any position that would make advancement possible. Willing to go anywhere but prefers New York, Detroit, Chicago or vicinity.

J-284 Associate-member, age 26, married, nine years' experience machine shop, foundry and general engineering practice. Has filled position of engineer inspector to large inspection bureau handling large government and private contracts comprising all kinds of mechanical construction. Desires change to avoid continual travel and wishes position as assistant engineer, superintendent or production engineer. Location immaterial.

J-285 Mechanical engineer, age 33, married, graduate of leading engineering college, twelve years' practical experience, chiefly in the manufacture of boilers and general plate work in engineering and executive positions. Would be valuable as manager, assistant manager or chief engineer. At present employed.

J-286 Associate-member, broad experience in operating, thoroughly versed in power plant economics and qualified to design power houses, or operate existing plant to obtain maximum efficiency, desires position as chief engineer of power plant. At present in charge of power end of large automobile factory. Speaks Spanish.

J-287 Associate-member, age 27, married, Cornell, M.E., five years' experience in construction and operation of hydroelectric plants, large part of the time executive in responsible charge, desires position. Now employed in Utah but desires residence in lower altitude.

J-288 Junior member, M.E., age 27, seven years' experience in design of gasoline and kerosene engines, jigs, tools, power plant installations, and general equipment, desires position with reliable manufacturing or engineering concern.

J-289 Associate-member, Cornell M.E., broad engineering experience capable of handling men, now holding manufac-

turing executive position desires change. Would also consider position which requires knowledge of sheet steel for various requirements.

J-290 Member, technical education and fourteen years' general engineering experience, perfectly familiar with design, construction and operation of plants manufacturing cement, coal mining and coking plants; has made an especial study of elevating and conveying machinery in connection with cement making and coal handling. Has held positions as chief draftsman, mechanical engineer and superintendent. Now employed but to avoid traveling desires to get in touch with large company where experience and ability may gain him a permanent position.

J-291 Experienced designer with broad experience in metal-working machinery and tools wishes to get in touch with concern which would undertake the manufacture of new line of medium sized machines. Location middle west.

J-292 Associate-member, fourteen years' experience in operating and superintending power plants, at present holding position as chief engineer of several plants, desires similar position or one as erecting superintendent, foreman or maintenance man. Position preferred where there is an opportunity to work up to executive position.

J-293 Junior member, Columbia graduate, experienced in design and construction work, desires permanent position in New York or vicinity. Prefers commercial or sales work. At present employed.

J-294 Associate-member, age 41, Lehigh University graduate in mechanical engineering, with eighteen years' varied experience in mechanical, electrical and civil engineering lines, involving design, supervision and direct charge of construction work, plant operation, purchasing, reports, etc., all in connection with electric railways, lighting plants, power and industrial plants, wishes an executive position as manager, superintendent, or sales engineer, with large field and responsibility. At present employed. Southern location preferred.

J-295 Member, graduate of United States Naval Academy, age 33, married. At expiration of six years' active service in the Navy, resigned honorably; has been several years in the employ of large corporations in executive position, desires operating executive position, or other connection, where education, experience and capacity for work count. Location immaterial.

J-296 Member, mechanical engineer, age 35, graduate of Worcester Polytechnic Institute, twelve years' practical experience in design, construction and operation of machinery and manufacturing equipment for power plants and machine shops, also building construction. Ten years with present company. Has had broad experience in work of brass and iron foundries, grinding, polishing, japanning, plating, forging, hardening and machine departments, also in plumbing, millwright, carpenter, electrical and plant work. At present in charge of engineering department for large concern.

J-297 Member with fifteen years' experience in the development and application of pumping machinery would like engagement with large industrial works. East preferred.

J-298 Member, technical man with twenty years' experience in designing, building and general engineering work, capable of managing and assuming responsibility, energetic, ambitious and reliable, desires position with well established company. Location preferred, eastern states.

J-299 Member, age 37, graduate Massachusetts Institute of Technology, thoroughly experienced in the design, development and manufacture of special automatic machinery, dies, tools, electrical devices and fittings of all kinds, furnaces, electro-galvanizing, etc., has taken out a large number of patents. At executive, knows what economy in production

means and how to obtain it. At present chief engineer of large corporation, but desires to change.

J-300 Junior member, age 26, Swarthmore graduate, at present superintendent of factory making fire apparatus, familiar with costs, brass foundry and forge shop production, desires position in engineering department of concern manufacturing standardized products. Salary \$150. Location eastern states, preference, Philadelphia.

J-301 American Member of the Society, technical graduate who has resided in China for the past five years, with wide experience with machinery, would like to get in communication with American firms wishing to open branch manufactures in China or who would like an agent to represent them in that country.

J-302 Graduate mechanical and chemical engineer with four years' teaching, and various power plant and oil mill experience, desires responsible position with some mechanical-chemical industry. At present employed.

J-303 Technical graduate, M.E. and C.E. with wide experience in teaching and consulting engineering work, wishes position as chief engineer or professor of mechanical engineering in university of good standing. Speaks French. Salary \$4000.00. Is open for immediate engagement.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.M.E.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Transactions, vol. 35. *New York, 1915.*

ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS. Proceedings, June 22-25, 1915. *Milwaukee, 1915.* Gift of Association of Railway Telegraph Superintendents.

ASSOCIATION OF TRANSPORTATION AND CAR ACCOUNTING OFFICERS. Proceedings, June, 1915. Gift of Association.

BUREAU OF RAILWAY ECONOMIES. List of references on the use of Railroads in War. *Washington, 1915.* Gift of Bureau of Railway Economies.

CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE. Year Book, 1915. *Washington, 1915.* Gift of Carnegie Endowment for International Peace.

CONNECTICUT SOCIETY OF CIVIL ENGINEERS. Papers and Transactions for 1914 and Proceedings of the 31st Annual Meeting, Feb. 9-10, 1915. *New Haven, 1915.* Gift of Connecticut Society of Civil Engineers.

GRAPHIC METHODS AND THE PRESENTATION OF THIS SUBJECT TO FIRST YEAR COLLEGE STUDENTS, M. F. P. Costelloe. Reprint from The Nebraska Blue Print, Apr., 1915. Gift of Iowa State Drainage Association.

INDEX OF PAPERS AND SUBJECTS DISCUSSED BY RAILWAY CLUBS FROM MAY 31, 1914-MAY 31, 1915. Gift of New York Railroad Club.

IOWA STATE DRAINAGE ASSOCIATION. Proceedings of Eleventh Annual Meeting, 1915. *1915.* Gift of Association.

MÜNCHEN, KÖNIGLICHE BAYERISCHE TECHNISCHE HOCHSCHULE. JAHRESBERICHT, 1913-14. Gift of Königl. Bayerische Technische Hochschule in München.

NEW ORLEANS, LA. SEWERAGE AND WATER BOARD. Thirtieth Semi-Annual Report. *New Orleans, 1914.* Gift of Sewerage and Water Board.

PHILADELPHIA. DEPARTMENT OF PUBLIC WORKS. Annual Report, 1913. *Philadelphia, 1913.*

Highways. A problem in municipal housekeeping.

Plain talk about public works. *Philadelphia, 1914*. Gift of A. S. M. E.

PROPERTIES OF STEAM AND AMMONIA, G. A. Goodenough. *New York, John Wiley & Sons, 1915*. Gift of Publisher. Price \$1.25.

These tables are based on formulae published in Bulletins 66 and 75 of the Engineering Experiment Station of the University of Illinois. They give the thermal properties of steam saturated and superheated and ammonia, with the necessary logarithms and conversion tables. W. P. C.

RAILWAY LIBRARY AND STATISTICS, Sleson Thompson, 1914. *Chicago, 1915*. Gift of author.

ROYAL SOCIETIES CLUB. Rules, by-laws, list of members. *London, 1914*. Gift of A. S. M. E.

SPECIAL LIBRARIES, R. H. Johnston. Reprint of Manual of Library Economy, Chapter VIII. *Chicago, 1915*. Gift of Bureau of Railway Economics.

STREET PAVING AND MAINTENANCE IN EUROPEAN CITIES. A Report by H. W. Durham. *New York, 1914*. Gift of Ralph Folks, Commissioner of Public Works, Borough of Manhattan.

THEORY AND EXPERIMENTS IN FOLLOWING PLANE MACHINES. Charles R. Whittemann. *1915*. Gift of Aeronautical Society of America.

TUFTS COLLEGE. ANNOUNCEMENT OF THE ENGINEERING SCHOOL 1915-16. *Tufts College, 1915*. Gift of Tufts College.

VALVES AND VALVE GEARS, F. DeKonde Furman, vol. II. *New York, John Wiley & Sons, 1915*. Price \$2.00. Gift of publisher.

This volume treats of valves for gasoline, gas and oil engines, and is illustrated by detail drawings. W. P. C.

GIFT OF MRS. DAVID N. MELVIN.

Mrs. Melvin has presented to the Society all of the books forming the technical library of her late husband, a member of the Society since 1880. The collection, about 500 volumes, comprises a set of Engineering and Van Nostrand's Eclectic Magazine, a set of the Transactions of the Society, and a large collection of modern textbooks.

GIFT OF C. W. RICE

INSTITUTION OF CIVIL ENGINEERS. Descriptive Pamphlet of New Building. Jan. 1914.

PUBLISHED MONTHLY BY

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

THIRTY-SIXTH ANNUAL MEETING

New York City, December 7 to 10

PART LIST OF TOPICS TO BE DISCUSSED

Abrasive Wheels	Hydraulic Power Plants
Accident Compensation	Locomotive Axles
By-Product Gas Producers	Oil Engine Vaporizers
Chimney Proportions	Orifice Gas Meters
Electric Elevators	Passenger Car Trucks
Electrically-driven Tools	Prevention of Corrosion
Engineering and the Executive	Protection of Workers
Fire Tube Boilers	Safety Methods
Foundations	Steam Pipe Coverings
Heating Textile Mills	Strength of Stoneware
Higher Steam Pressures	Turbines vs. Engines
High Vacuum Condensers	Water Tube Boilers

PART LIST OF AUTHORS OF PAPERS

Allen H. Babcock	C. F. Hirschfeld, Jun. Am. Soc. M. E.
Paul A. Bancel, Jun. Am. Soc. M. E.	Louis Illmer, Mem. Am. Soc. M. E.
J. S. Barstow	David Lindquist
James E. Boyd	Arthur H. Lynn
L. C. Brooks, Jun. Am. Soc. M. E.	L. B. McMillan, Jun. Am. Soc. M. E.
Robert Cramer, Mem. Am. Soc. M. E.	Charles T. Main, Mem. Am. Soc. M. E.
F. W. Dean, Mem. Am. Soc. M. E.	Anatole Mallet, Hon-Mem. Am. Soc. M. E.
Albert G. Duncan, Mem. Am. Soc. M. E.	A. L. Menzin, Assoc-Mem. Am. Soc. M. E.
Geo. H. Gibson, Mem. Am. Soc. M. E.	Mark A. Replogle, Mem. Am. Soc. M. E.
Hollis Godfrey, Mem. Am. Soc. M. E.	Roy V. Wright, Mem. Am. Soc. M. E.
Ernest O. Hickstein, Jun. Am. Soc. M. E.	

For program of the meeting see page XV.

MEETINGS OF LOCAL SECTIONS

November 4, Buffalo, N. Y. Subject: Multiplicity of Cylinders in Automobiles, by J. G. Vincent, Mem. Am. Soc. M. E. and Vice-President of the Packard Motor Car Company.

November 17, New Haven, Conn. Subject: Machine Tools.

November 23, Philadelphia, Pa. Subject: Industrial Safety, by William P. Barba, Mem. Am. Soc. M. E. and Vice-President of the Midvale Steel Company.

November 30, Boston, Mass. Subject: Gainful Pursuits open to Soldiers who have been injured, Frank B. Gilbreth.

INTERNATIONAL ENGINEERING CONGRESS

TWO hundred and forty-one papers were presented at the fifty-two sessions of The International Engineering Congress, 1915; and although the present international conditions have hampered somewhat the exchange of all but military engineering thought and experience, sixty-six of the papers contributed were by authors residing outside the United States. In addition to those from our own country, papers were received from Argentina, Australia, Austria, Canada, Chile, China, England, France, India, Italy, Japan, the Netherlands, Panama, Russia, South Africa, Sweden and Switzerland. It is interesting to note that forty-eight authors of papers coming from the United States were members of the Society.

CONCEPTION AND ORGANIZATION

The Congress was conceived in 1911 when a meeting of representatives of the American Society of Civil Engineers and The American Society of Mechanical Engineers recommended that engineers from the great associations of the world be called together in 1915 to participate in the celebration of the completion of the Panama Canal. A further conference in 1912 led to the formation of plans to hold the Congress in conjunction with the Panama-Pacific International Exposition, 1915. The enterprise was organized and conducted under the auspices of the American Society of Civil Engineers, American Institute of Mining Engineers, American Institute of Electrical Engineers, The So-

SUBJECTS OF THE CONGRESS

Partial List of Subjects Included in the Papers Presented

AGRICULTURE	FORGINGS	PULVERIZED COAL
ALLOYS	FOUNDING	RAILWAYS
ALLOY STEELS	FUELS	REFRIGERATION
ALUMINUM	GRINDING	RIVERS
AVIATION	HEATING	SAFETY
AUTOMATICS	HIGHWAYS	SANITATION
BOILERS	HYDRAULICS	SEWAGE DISPOSAL
BRIDGES	HYDROELECTRICS	SHIPS
CARGO HANDLING	ILLUMINANTS	SIGNALS
CASTINGS	IRON	STEEL
CITY PLANNING	IRRIGATION	STREETS
CLAY PRODUCTS	LOCOMOTIVES	TERMINALS
COMPRESSED AIR	MACHINE TOOLS	TESTING MATERIALS
CONCRETE	MANAGEMENT	TIMBER
COPPER	METALLOGRAPHY	TRACTORS
DOCKS	METAL WORKING	TRANSIT
DUST PREVENTION	METALLURGY	TUNNELS
ECONOMICS	MINING	TURBINES
EDUCATION	MOTION STUDY	UTILITIES
ELECTROLYSIS	NAVIGATION	VEHICLES
ELECTRIC MOTORS	ORE DRESSING	WATERWAYS
ENGINES	ORDNANCE	WATER SUPPLY
FIRE PROTECTION	PANAMA CANAL	WATER WHEELS
FLOOD CONTROL	POWER STATIONS	WELDING

ciety of Naval Architects and Marine Engineers, and The American Society of Mechanical Engineers. Major General Geo. W. Goethals, the builder of the Panama Canal, was elected Honorary President and nineteen Honorary Vice-Presidents were chosen. Besides its president and secretary, each of the organizing societies elected four representatives on the Committee of Management; the six representatives of the Society on the Committee were Dr. John A. Brashear, Calvin W. Rice, Chas. T. Hutchinson, Thos. Morrin, T. W. Ransom and C. R.

Weymouth. Dr. Wm. F. Durand served as Chairman of the Committee of Management; W. A. Cattell as Secretary-Treasurer, and E. J. Dupuy as Executive Secretary. There were six permanent sub-committees of the Committee, as well as six special sub-committees, taking care of the administrative and executive details of the organization.

MEMBERSHIP

To secure for those engineers cooperating in the Congress a permanent record of its proceedings, a plan of membership by subscription was inaugurated, and 3082 enrollments were made, 816 of which were from foreign countries. Each subscriber received the right to participate in the deliberations and privileges of the Congress, and the entitlement to a volume reporting the general proceedings of the Congress and containing indexes and digests of other volumes, and one volume of the transactions.

THE CONGRESS

The Congress opened with a general session in the main hall of the Auditorium Building, Civic Center, San Francisco, on Monday, September 20, at 10 a. m. An address of welcome was delivered by Hon. James Rolph, Jr., Mayor of San Francisco, and other speakers were Maj. Gen. Goethals and the Honorary Vice-Presidents present, as well as Chas. C. Moore, President of the Panama-Pacific International Exposition.

The afternoon of the first day was devoted to a general session on the Panama Canal, six papers being presented, including an Introduction by Maj. Gen. Goethals. There followed during the six days of the Congress, four sessions on Waterways, four on Irrigation, five on Municipal Engineering, five on Railway Engineering, five on Materials of Engineering Construction, six on Mechanical Engineering, three on Electrical Engineering, three on Mining Engineering, five on Metallurgy, seven on Naval Architecture and Marine Engineering, and four sessions devoted to miscellaneous topics including Aviation, Refrigeration, Agricultural Engineering, Engineering Education, and Heating and Ventilation.

The total registration at the Congress during the week was 750. Foreign members and delegates attended from Austria, Australia, Canada, Germany, Switzerland, China, Cuba, France, Guatemala, Japan, Mexico, the Netherlands and Sweden.

THE PAPERS

A complete list of titles of the papers and their authors was included in the full program of the sessions of the Congress published in the September issue of The Journal. The papers covered practically every field of engineering art and the general theme of each was to review recent progress and development in its particular subject and outline the tendencies of present effort. To several of the papers were appended bibliographies, making them a valuable index to the literature of current engineering practice. As members of the Society may be interested in the contributions of their fellow-members, brief synopses of these particular papers are given below; these are listed in the same order as in the program of the Congress, and under the same heads.

The abstracts are taken from the prints of the advance papers given out at the meetings.

BRIEF ABSTRACTS OF PAPERS BY MEMBERS OF THE SOCIETY PRESENTED AT THE
INTERNATIONAL ENGINEERING CONGRESS

WATERWAYS

HYDRAULICS OF THE LOCKS OF THE PANAMA CANAL, R. H. Whitehead

This paper discusses the arrangement of valves and culverts and expectation of the design of the Canal locks; observed characteristics of the system and importance of good distribution; discharge through lateral culvert openings when filling locks, neglecting friction; recommendations for design of lateral culverts and their openings; friction losses; discharge through openings corrected for losses; recommendation for total lateral culvert distribution; determination of time equation of flow; filling and emptying curves for Pedro Miguel Lock; calculation of value of dynamic head for complex culvert systems; the rising-stem valves; miter gates and the force required to operate them; current in locks due to difference in salinity.

THE PROVINCE OF WATERWAYS IN THE INTERNAL COMMERCE AND DEVELOPMENT OF A COUNTRY, Brig. Gen. W. H. Bixby

IRRIGATION

ECONOMIC ADVISABILITY OF IRRIGATION, Dr. F. H. Newell

This paper is an exposition of the present condition of development of irrigation practice and an indication as nearly as may be of the principal economic reasons why irrigation has been and should be practiced. It includes a consideration of the causes which have led to the present delay in entering upon or completing large works and indicates some of the lines along which further progress may be expected.

MUNICIPAL ENGINEERING

THE DISPOSAL OF SUSPENDED MATTERS IN SLUDGE, Rudolph Hering

The paper is a discussion of the treatment of the liquid refuse of a city, with special reference to securing healthful results and preventing nuisances from the suspended matter contained in refuse. While it has been known for a long time that inoffensive decomposition of sewage can be secured by efficient aeration, agreement does not yet exist as to the most effective and economical way of applying and diffusing the air.

PUBLIC UTILITIES, Dr. Alex. C. Humphreys

"I am convinced that, under American conditions, the system of private ownership of public utilities is best for the citizens and the consumers," was an expression by Dr. Walton Clark in a minority report to the Commission on Public Ownership of the National Civic Federation. The author reiterates this conviction and devotes his paper to outlining the dangers of unreasonable regulation of utilities.

RAILWAY ENGINEERING

RECENT LOCOMOTIVE DEVELOPMENT, George R. Henderson

Within recent years there have been four distinct lines of advancement in steam locomotives—size, type, details and adjuncts. Utilizing the Mallet principle and adding a driving unit under the tender, we now have running a locomotive of 755,000 lb. adhesive weight and 160,000 lb. tractive force. Cast steel has probably exerted more influence on the design details of the locomotive than any other single item. The increased size and weight of locomotives has brought about

the addition of a number of special features; such are power reversing mechanisms, automatic fire door openers, pneumatic grate shakers, coal pushers and mechanical stokers.

ROLLING STOCK OTHER THAN MOTIVE POWER, Arnold Stucki.

This paper deals with the car equipment used by the railroads of the U. S. and Canada and points out the improvements made during the last decade. These latter have been in the direction of safety and comfort of passengers, strength and efficiency of construction, efficiency in handling freight and in moving trains, and protecting freight. The introduction by the Erie Railroad in 1904 of the all-steel passenger car resulted in an evolution of passenger equipment, and tremendous progress has been made, too, by the use of steel in freight car construction.

THE FLOATING EQUIPMENT OF A RAILROAD, F. L. DuBosque

This paper describes in considerable detail the floating equipment of a railroad operating in New York Harbor, that employs 10 ferry boats, 31 tug boats, 7 self-propelled barges, 68 ear floats, 71 covered barges, 71 derrick barges and 20 coal barges. The dimensions of the units are given, as well as descriptions and illustrations of them and the service in which they are employed.

MATERIALS OF ENGINEERING CONSTRUCTION

CONCRETE AGGREGATES, Sanford E. Thompson

While uniform Portland cement is now manufactured at low cost, the other principal ingredient of concrete, the aggregate, has not been thoroughly standardized. Series of tests have been made, and are still in progress, for the clearer formulation of laws of concrete mixture. On account of the variation in strength of mortars made with different sands, sand and other aggregate should always be tested. Strength; permeability of the mortar and concrete; effect of different brands of cement; effect of frost action; effect of fire; characteristics of yield, density, chemical composition, mechanical analysis and amount of organic matter, are factors which should be considered.

ALLOYS AND THEIR USE IN ENGINEERING CONSTRUCTION, W. Reuben Webster

The paper is more particularly devoted to the most extensively employed group of alloys of which copper is the base. It discusses the physical properties and characteristics of the brasses and bronzes and of the alloys containing copper, zinc, lead and tin, usually known as red brass and varying in strength, toughness, cost, color and machining qualities according to their composition.

TESTING FULL SIZE MEMBERS, Gaetano Lauza

This paper is retrospective, considering the meaning and scope of the term *Testing Full Size Members*; the importance of making such tests and the reasons therefor; the need for their performance on a systematic and well organized plan, so that the results obtained may be of the greatest value in engineering practice; an enumeration of the kinds of tests that have thus far received the most attention; a summary of the tests most needed, including a consideration of certain classes of tests concerning which comparatively little, and of others concerning which no progress has been made thus far, and a consideration of the value and possibilities of coöperation in making full size tests.

MECHANICAL ENGINEERING

RECENT ADVANCES AND IMPROVEMENTS IN FOUNDRY, Thomas D. West

Since the introduction of electricity and compressed air as a motive power, improvements in the construction of foundries and their appliances have been steady and persistent. In keeping with the improvements for handling raw materials are those for mixing, melting, molding, core making and cleaning of castings. The production of ferrous and non-ferrous metals has been greatly assisted by chemical studies. The advancement in core making and molding has been due to the use of molding machines. The cleaning of castings by sand blasting, pneumatic and hydraulic tools, and electrical appliances has progressed. Labor saving appliances and the adoption of specializing have operated to improve materially the quality of castings.

FORGINGS FROM EARLY TIMES TO THE PRESENT, C. von Philp

The different methods of producing forgings are hammering, pressing and squeezing, extruding, die-casting and bending. With the development of the steam hammer, with its valve gear, the size of forgings made by hammering has been greatly increased. The art of die forging has developed to such an extent that all kinds of intricate forgings that could never be thought of in the days of the early methods can now be made. Owing to the high speed of the modern hydraulic forging press, this can now compete with hammers in producing forgings of even comparatively small size. The extruding process is being used in the manufacture of pipes and wires of lead, shapes in brass, valves of high grade steel, rods, etc. Carburetors and instruments are being manufactured by the die casting method which has taken quite some time to develop. Bending was mostly employed for flanging boiler heads, but with the advent of the steel railroad car, bent forgings have been found more economical than structural shapes; they are also largely used in the shipbuilding trade.

PERMANENT SHOPS, PACIFIC TERMINALS—PANAMA CANAL, H. D. Hinman and A. L. Bell

MACHINE SHOP EQUIPMENT, METHODS AND PROCESSES, E. R. Norris

The greatly increased feeds, speeds and depths of cut rendered possible by the use of Taylor and White's high speed steel made it necessary for the builders of machine tools to redesign their tools along heavier lines and with greater pulling power, and later to equip the machines with quick changing and automatic attachments to facilitate the handling between cuts. The paper considers special alloy steels, their composition, treatment, application and effect on machine shop practice; machining with edge tools; grinding as a final machining operation and electric driving for machine tools.

MACHINE SHOP EQUIPMENT, METHODS AND PROCESSES, H. F. L. Orcutt

This paper reviews the progress in American and European machine tools in the last fifteen years. As the most important improvements, the author selects single pulley drive, change gear boxes, independent motor drive, ball and roller bearings, speeding up idle movements, provision for cutting and cooling fluids, better lubrication, increased precision, chain drive and rigidity in design. He describes in detail recent advances in grinding, gear cutting and tooth finishing, and auto chucking machines.

AUTOMATICS, R. E. Flanders

From an early period lathes and, later, drilling machines have been provided with self-actuating feeds, and are thus automatic. As self-actuating feeds became the rule, something more was required to justify the use of the term, which has of late years only been applied to machine tools in which practically all the movements are self-actuating. The multiple spindle automatic screw machine is now finally established, but the large multiple spindle automatic lathe is still a new venture. Milling machines, drill presses, gear cutting machines, grinding machines furnish other examples of automatics used in American machine shop practice.

THE INTERNAL COMBUSTION ENGINE OF THE YEAR 1915.

THE GAS POWER SYSTEM. A SURVEY OF ITS STATUS IN 1915, Prof. C. E. Lueke

After a fifteen-year period of close study of performance, design, construction and adaptation to service, the internal combustion engine and the gas power system occupy to-day a definite place in the scheme of industrial affairs and are so firmly established that they will never be replaced. Today the internal combustion engine is thermally more efficient, size for size and fuel for fuel, than the steam engine in any size in which it can be built, and the difference in fuel combustion is greater the smaller the size because efficiency of steam systems fall off very rapidly with decrease of size, while the internal combustion engine does not.

With the present state of knowledge on the properties of explosive mixtures and the distillation, vaporizing, gasification and combustion of fuels, the first fundamental step in the design of gas engines for specified performance is on a truly scientific basis.

Mechanism designers and power engineers are devoting attention to the mechanical perfection of apparatus operating on the two adopted cycles, the Otto and the Diesel, both of which have high enough efficiency characteristics both promised and realized for some time to come.

THE DIESEL ENGINE IN AMERICA, Max Rotter

This paper includes historical and fundamental information regarding the Diesel, or high compression constant pressure oil engine, and the so-called semi-Diesel, or low compression oil engine. It compares the 2-cycle and the 4-cycle types. It considers the design details of Diesel engines, including fuel atomizing elements, cylinders and heads, pistons and accessories and lubrication. A part of the paper is devoted to the consideration of fuels and in another are mentioned and briefly described several Diesel type engines built in the United States. Typical indicator diagrams, both maximum and no-load, are given, enabling comparisons to be drawn, and the details described are well illustrated.

WATER WHEELS OF THE PRESSURE TYPE, Arnold Pfau

This paper is divided into eight chapters—theoretical definition of pressure wheels; previous and present art; applicability; classes, types and characteristics; description and selection of type; efficiencies and tests; accessories, and some general remarks and suggestions—a knowledge of the basic principles of water wheels is presumed. Wheels are classified according to the direction of flow of the water with reference to the shaft, as follows: radial outward discharge, diagonal outward discharge, axial discharge, diagonal inward discharge, radial inward discharge, and combined radial or di-

agonal inward axial and diagonal or radial outward discharge; a history of each of these classes is given.

The Francis turbine, the types of runners for which are now elaborately classified, has displaced all other types of reaction turbines and manufacturers now offer these turbines of large capacities for heads as high as 1000 ft. With a single runner, vertical shaft turbine, efficiencies can be obtained which exceed 90 per cent.

WATER WHEELS OF IMPULSE TYPE, W. A. Doble

SAFETY ENGINEERING, Frederick R. Hutton

Of the phases of the problem of industrial safety, the mechanical engineer is directly concerned with the prevention, by safety apparatus and otherwise, of accidents originating from the sudden injury to the body through the motor forces in industry. Complete safety at the origin of power calls for engine stops; lattice cages safeguard workers from the moving parts of engines. Belts and pulleys and chain drives are guarded with sheet steel or lattice, as are moving parts of machines and individual tools.

The forge and the rolling mill, the steel works and the blast furnace, the saw mill and the chemical process plant, the textile mill and the dye-house, the electric furnace and the power transmission line and switches—each offers its own problems and all have found their satisfactory safeguards.

MOTOR VEHICLES; UTILITY TYPE, Arthur J. Slade

These are defined as self-propelled vehicles designed to be operated without rails, for the primary purpose of transporting materials, products, passengers or apparatus, especially for business purposes or for fire, profit, emergency work or special utility service; as distinguished from private personal use by the owner or renter for enjoyment or convenience.

The paper presents the results of the author's observation of the development, during the past decade, of the general types of commercial motor cars which have to any marked extent become standardized, and gives the present status as to features of design and application, and the tendencies of future development. The storage battery electric and the internal combustion engine driven vehicle are first considered, and special application of each or combinations of both are then referred to.

COMPRESSED AIR IN THE ARTS AND INDUSTRIES, W. L. Saunders

The forcing of compressed air through the molten metal in the Bessemer converter, and the consequent decarbonizing action has made this method of steel making possible. To the forced draft in the boilers of vessels may be, in part, attributed the high power developments in restricted space for boiler capacity, as illustrated in naval practice, in torpedo boats, destroyers, etc. Bellows, rotary fans, blowing engines, rotary blowers, steam jet blowers, and other similar appliances are now used in the ventilation of mines, of buildings and generally in the removal of vitiated gases and in the supplying of gases and air for chemical purposes. Diving apparatus, bells, caissons and tunnel shields play a most important part in the field of engineering. Compressed air-operated locomotives are becoming generally employed. The employment of compressed air has solved the problem of braking railway trains. The pneumatic despatch tube as a conveyor has come into wide use. A pneumatic gun of 15-in. bore has been developed. The Whitehead torpedo is

driven by compressed air. In mines and quarries a large central compression plant has come to be accepted as the most effective means of providing power.

ELECTRICAL ENGINEERING

THE EFFECT OF HYDRO-ELECTRIC POWER TRANSMISSION UPON ECONOMIC AND SOCIAL CONDITIONS, WITH SPECIAL REFERENCE TO THE UNITED STATES OF AMERICA, Frank G. Braun

The stability of any civilization depends on the fact that it consumes less than it produces, and as with an increasing population, the most efficient methods must be employed for all operations, nature's naturally replenished sources of power must be used instead of consuming wood, coal, oil, etc.; and the most natural source of power is falling water, which nature is annually producing. This water power, converted into the electric form for distribution and supplied to electric appliances for conversion into the form desired, at the place desired, is the most efficient and convenient system imaginable.

The author expects to see central stations of 100,000 kw. and trunk transmission lines constructed to connect a large number of these stations throughout the continent, with branch substations and lines over the entire country. The prime movers will be limited to water wheels located at favorable water power sites and steam turbines at sources of cheap fuel, coal, oil or gas.

ELECTRICAL AND MECHANICAL INSTALLATIONS OF THE PANAMA CANAL, E. Schildhauer

ELECTRIC WELDING, C. B. Anel

There are three clearly defined processes of electric welding—are, incandescent and electro-percussive—each more or less limited to a certain field. The first includes the Zenero, Bernados and Slavianoff processes; the second, the La Grange-Hoho and the Thomson processes.

The arc processes are autogenous, in that welding can be accomplished without pressure, simply by allowing the metals to melt under the influence of the electric current, then to mix and unite as they cool; the incandescent and electro-percussive processes, however, invariably require pressure as a necessary adjunct to their successful accomplishment. The paper compares these processes and considers their applications.

THE ELECTRIC MOTOR AS AN ECONOMIC FACTOR IN INDUSTRIAL LIFE, David B. Rushmore

The present highly developed civilization is dependent upon the utilization of the stored energy in our natural resources or upon the energy from the sun, either directly or through water powers; and the utilization of this energy on a broad scale has been economically possible only by the use of electricity.

Electricity is the most convenient form in which to transmit and apply energy, and the electric motor produces motion and torque at various speeds and in different directions.

The paper discusses the various types of electric-motor designs and gives examples of their applications. It outlines the fields of electric motor application.

THE INFLUENCE OF THE ELECTRIC MOTOR ON MACHINE TOOLS, A. L. DeLeenw

The electric motor has influenced the machine tool beneficially along the following lines: better knowledge of the data governing the design of machine tools; greater possibilities in regard to power; closer control of a machine tool in regard to speeds, stopping, starting, etc.; flexibility of the use of machine tools, by making them portable and by making a better shop construction possible. The most marked and beneficial influence of the electric motor on machine tools has been the bringing into view of the lack of fundamental knowledge of machine tools, and it has opened up a new era—which may be called the scientific era—for the machine tool.

EFFECT OF ELECTROLYSIS IN ENGINEERING STRUCTURES, Albert F. Ganz

The principal engineering structures which may be effected by electrolysis from stray electric currents are electric railway tracks, and iron or steel structures supporting these tracks; underground lead sheathed cable systems; underground piping systems and steel foundations of buildings, bridges, etc., and reinforced concrete structures. The paper gives information, based on the writer's personal experience and on direct inquiry, illustrating cases of and remedial measures applied to affected structures.

MINING ENGINEERING

THE VALUATION OF ANTHRACITE MINES, R. V. Norris

The problem of valuation of coal in the anthracite region in northeastern Pennsylvania is complicated by the rapid variations in the thickness and quality of the beds, by the numerous faults and still more numerous convulsions. The basins are traversed by endless anticlinals and synclinals, and within short distances good coal is changed to crushed and worthless dirt. The value of anthracite land has rapidly increased, until at the present time \$3,000 per acre is considered only a fair price for good virgin coal land. In 1907 great advances were made in assessed valuation, and assessments imposed have been resisted in the courts; at the present time assessed valuations of \$175 to \$300 per foot-acre are attempted to be imposed.

ORGANIZATION AND STAFF OF MINING COMPANIES, W. H. Shockley and R. E. Crabston

METALLURGY

IMPROVEMENTS IN DESIGN AND CONSTRUCTION OF MODERN COPPER PLANTS, Chas. H. Repath

The rapid progress and development in mining and smelting in modern times has been due to the general development in all the arts and sciences and the increase in the general intelligence of the men who are engaged in this class of work. Mechanical appliances have been perfected and adapted to the problem of handling materials in every department and new machinery invented to do work that originally took large numbers of laborers. Nearly all large companies maintain experimental and testing departments, in charge of which are competent engineers and metallurgists, who are engaged constantly in the development of new processes and in perfecting the old ones that are used in the treatment of ores and in the conservation of the values that were previously wasted.

METALLURGY

THE DEVELOPMENT OF ELECTROLYTIC COPPER REFINING,
Lawrence Addicks

Three distinct stages in the development of copper refining may be noted: early development; tonnage extension, and efficiency work. The first period ends with the development of mechanical lading, general use of cranes for handling electrodes and the undertaking of the building of the Raritan Copper Works in 1898. The second period covers the next six years, which saw the creation of the first really large plants; and the third, the ten years just closed, with plenty of work yet in sight to put refining on a finished basis.

Both the series and the multiple processes have given relatively pure bullion and there is little to choose between them. However, the multiple process is much less sensitive to impurities and requires less skill in operation, and has been adopted by those later entering the refining business. SURFACE COMBUSTION (WHAT IS IT?), C. E. Lucke

NAVAL ARCHITECTURE AND MARINE ENGINEERING

RIVER, LAKE, BAY AND SOUND STEAMERS OF THE UNITED STATES, Andrew Fletcher

This paper includes authentic drawings of the midship cross sections with scantlings, deck plans, elevations and a data sheet of general dimensions, draft, displacement, trial speed and motive power of a number of well-known and successful steamers of the United States. The steamers selected are of the steamboat type, with the exceptions of the turbine steamers "Yale" and "Harvard"; the steamer "Governor Cobb," the first Parsons marine-turbine steamer built in the U. S., and the turbine steamer "Belfast."

SPECIAL TYPES OF CARGO STEAMERS FOR THE U. S. COAST TO COAST TRADE THROUGH THE PANAMA CANAL, Geo. W. Dickie

The character of the inter-coast trade demands a special type of vessel. The type demanded by part of the East-bound freight and all of the West-bound is not suitable for the economical transportation of lumber, which is the predominating part of the East-bound. The paper describes a vessel combining the good qualities of both the shelter-decker for general cargoes and the lumber steamer, and sacrificing the special functions of neither. Some of the objects are accomplished by making the lumber type of vessel deeper in the hold, adding a middle deck, carrying the hatches up through the deck load by making a continuous trunk for them, making in effect a partial shelter-deck type.

THE SUBMARINE, L. Y. Spear

SOME ECONOMIC FUNDAMENTALS OF FREIGHT HANDLING,
D. B. Rushmore

This paper gives a general outline, from an economic as well as an engineering standpoint, of the problems involved in freight handling, and discusses scientific methods of investigation, analysis and construction as the necessary means of solution of these problems. These problems have to do with the installation of mechanical apparatus in present terminals and for use with present ships, cars and warehouses; the development of ports and harbors and location and design of docks, terminals and warehouses; as well as the attempted standardization of package sizes. The field offers

attractive possibilities for central station power loads and is one which will develop in the near future.

FUEL OIL, Ernest H. Peabody

THE APPLICATION OF DIESEL OR HEAVY OIL ENGINES TO MARINE PROPULSION, G. C. Davidson

The paper outlines the status of the Diesel engine as applied to marine propulsion today, and includes examples of present types of engines.

The Nobel Company was the pioneer in applying Diesel engines to marine purposes. Long before oil engines were used on ships in other countries, the Nobels had a fleet of Diesel-engine ships in operation in Russia. The Burmeister and Wein Company has been very successful in applying its heavy 4-cycle engines to merchant vessels.

MISCELLANEOUS

AGRICULTURE AND THE ENGINEER, J. B. Baldwin

A large part of agricultural production involves many mechanical operations not dissimilar to those used in the factory. Agricultural engineering embraces farm machinery, farm power, farm structures, rural sanitation, manufacture of agricultural products, drainage, irrigation and public roads. The first four of these relate more directly to the farm, and are naturally of more recent development, while the last three relate to the agricultural community and have reached a higher state of development. The paper outlines the field for the agricultural engineer and discusses the training required.

SOME CONSIDERATIONS REGARDING ENGINEERING EDUCATION IN AMERICA, G. F. Swain

This paper discusses the general tendency and development of engineering education in this country. It outlines the elementary curricula of the early engineering schools, the graduates of which built our railroad systems and many of our great municipal works. It considers the difficulties of the more complex requirements and methods of today and suggests they may best be met by cutting off from the top of our present too elaborate and too widely expanded curricula, and in offering the bachelor's degree for a more general course in engineering science and the humanities, in which fundamental principles rather than practical applications are emphasized.

TECHNICAL EDUCATION FOR THE PROFESSIONS OF APPLIED SCIENCE, Ira N. Hollis

This paper relates to the professional side of applied science and discusses the methods in vogue in this country for training young men for the technical professions. It gives a schedule of studies in American technical schools, comparing the courses in three representative institutions; mechanical engineering schools are selected on account of the workshop courses. It concludes with a discussion of the theories of education as relating to the success or failure of a technical school, and a consideration of these theories applied to the modern American technical college with its mixture of undergraduate and professional studies.

DEVELOPMENTS AND PROGRESS IN "SCIENTIFIC MANAGEMENT" DURING RECENT YEARS, E. P. Lesley

MOTION STUDY AND TIME STUDY INSTRUMENTS OF PRECISION,
F. B. Gilbreth and L. M. Gilbreth

This paper is for the purpose of disseminating knowledge

of the methods and devices of waste elimination, particularly as to the devices used for making the measurements that enable waste to be eliminated. It outlines and illustrates methods of making time studies or processes of analyzing an operation into its elementary operations and observing the time required to perform them; and motion studies having to do with the selection, invention and substitution of the motions and their variables that are to be measured.

HEATING AND VENTILATION

HEATING AND VENTILATION, INTRODUCTORY PAPER, R. C. Carpenter

VACUUM, VACUO-VAPOR AND ATMOSPHERIC HEATING SYSTEMS, J. D. Hoffman

An analysis of the great changes in the methods of steam heating in the past twenty-five years shows that steam pressures in radiators and coils have dropped from 50 to 60 lb. gage to atmosphere and below. The most recent tendency towards simplicity is an atmospheric, two-pipe, gravity return system, with radiators controlled at inlet and open to atmosphere on end of return.

The paper describes in detail modern mechanical vacuum, vacuo-vapor and atmospheric systems and includes illustrations of the special fittings upon which the efficiency and satisfactory working of these systems are largely dependent.

THE VOLUMES OF PROCEEDINGS

It is planned to issue the volumes of proceedings between November and January, and members of the Society who did not enroll in the Congress, but who wish to obtain any or all of its publications, should communicate with E. J. Dupuy, Foxcroft Building, San Francisco, Cal. The final arrangement of publication is: Vol. 1, Panama Canal; Vol. 2, Waterways and Irrigation; Vol. 3, Municipal Engineering; Vol. 4, Railway Engineering; Vol. 5, Materials of Engineering Construction; Vol. 6, Mechanical Engineering; Vol. 7, Electrical Engineering and Hydroelectric Power Development; Vol. 8, Mining Engineering; Vol. 9, Metallurgy; Vol. 10, Naval Architecture and Marine Engineering; Vol. 11, Miscellaneous, including Aeronautics, Refrigeration, Agricultural Engineering, Engineering Education, Heating and Ventilation, Scientific Management.

SOCIAL AND ENTERTAINMENT FEATURES

On the evening of the opening day, a reception was tendered by the Committee on Management to the Honorary President, Vice-Presidents, delegates, members and guests of the Congress. This was held at the Palace Hotel.

A trip was made to Mount Tamalpais by some of the members and guests on Tuesday morning, while on Wednesday afternoon a party was conducted through the Panama-Pacific International Exposition by the local members of the Committee of Management.

In honor of the members and ladies, a lawn party

was given in the Faculty Glade, University of California, on the afternoon of September 23, and an automobile ride to points of interest in San Francisco was tendered the visiting ladies on the following afternoon.

The President and Directors of the Panama-Pacific Exposition designated Friday, September 24, as Exposition Engineers' Day. The delegates to the Congress with their ladies were invited to take part in the ceremonies held in the afternoon in the Court of Abundance in honor of the members of the engineering profession who had rendered especially distinguished service to the Exposition. On this occasion bronze plaques were presented to the nine engineers who built the Exposition. Preceding the ceremonies a luncheon was tendered the engineers in the Directors' quarters of the California Building.

On Friday evening a banquet at the Palace Hotel was given to the officers, delegates and members of the Congress and their ladies. Three hundred covers were laid. Prof. Durand acted as toastmaster, and the foreign vice-presidents were represented by Major Jean L. de Pulligny, of the French army. Brig. Gen. W. L. Sibert spoke in place of General Goethals, who had been called away to New York.

By the courtesy of the State Harbor Commission, Jerome Newman, Chief Engineer, a cruise and inspection trip was made along the San Francisco water front on Saturday, September 25, giving members an opportunity of inspecting the harbor and engineering works along the front.

THE RETURN EAST

For the purpose of showing members of the Congress the engineering works along the line of the Canadian Pacific Railway and the wonderful scenery through the Canadian Rockies, a special train leaving San Francisco on September 25 was run over the lines of the Southern Pacific and Canadian Pacific Railways to Chicago. This train took the members of the party through Portland to Seattle, where a Canadian Pacific Ry. steamer carried them to Vancouver. Here they were entertained royally by the British Columbia Electric Railway Company, Limited, and inspected the company's Coquitlan-Buntzen Hydro-Electric Development which provides electric energy for the city of Vancouver and other cities in lower British Columbia. Continuing through Ruskin, North Bend, Glacier, Lake Louise and Banff, the party arrived at Calgary on Monday, October 4. They were here the guests of the city, were entertained at luncheon at which the Mayor gave an address of welcome, and were shown by the City Engineer the new bridges and the headgates of the Canadian Pacific irrigation system. The big dam at Bassano was the last engineering objective, and the party passed from there through Moose Jaw and Minneapolis, arriving in Chicago on Thursday, October 7.

Left to right—L. F. LEURY, assistant electrical and mechanical engineer of the Exposition; H. D. DOWELL, chief structural engineer; SHIRLEY BAKER, assistant director of works; H. D. H. CONNICK, director of works; C. S. SCOTT, Wm. H. CROCKER, chairman of committee on buildings and grounds; TIMOTHY JOHN A. BRASHEAR, Prof. C. D. MARK, J. J. CARTY, C. C. VOGELSONG, commissaire; F. L. HUTCHINSON, CALVIN W. RICE, Lieut-Commander C. H.

ENGINEERS' DAY AT THE PANAMA-PACIFIC

ENGINEERS' DAY AT THE EXPOSITION

Friday, September 24, was Engineer's Day at the Panama-Pacific International Exposition. Ceremonies were held in the Court of Abundance, and the purpose of the gathering was well expressed in the remarks of Wm. H. Crocker, Chairman of the Building and Grounds Committee, who spoke as follows:

We are assembled here to-day, in this beautiful place, for the purpose of honoring nine of the engineers who worked faithfully in the construction of this Exposition. The Exposition officials wish to pay them special recognition and have chosen the time of the convening of the Engineers' Congress in order to signal these nine engineers who worked for the Exposition, in a more permanent manner than otherwise would be adopted. The work which these engineers did will never be forgotten. They had a great responsibility. It was due to their careful work that we were able to adjust our finances, adjust the work that was to be done, and so to handle the construction of the work as to make it possible under their direction. They did their work faithfully and well. They did their work within the appropriation and they accomplished it on time. I wish to mention emphatically the names of those who did this wonderful work. They are Harris D. H. Connick, Director of Works; A. H. Markwart, Assistant Director of Works; Guy L. Bayley, Chief Mechanical and Electrical Engineer; E. E. Carpenter, Chief Civil Engineer; Shirley Baker, Construction Engineer; H. D. Dowell, Chief Structural Engineer; William Waters, Superintendent of Construction; W. M. Johnson, Engineer of Fire Protection; L. F. Leury, Assistant Chief Mechanical and Electrical Engineer. I cannot emphasize too greatly the importance of the services of these gentlemen, and in order to show them the gratitude the Exposition officials feel toward them jointly and severally, President Charles C. Moore will present to each one of them a token of this occasion.

President Moore, referring to the occasion as the "recognition of the engineering profession," and ex-

pressing the sentiments of the Exposition in well chosen words, thereupon presented each of the engineers named with a beautiful bronze plaque of Florentine design and inscribed with the legend "This is in Recognition of Services as One of the Engineers of the Panama-Pacific International Exposition, by its Board of Directors, on Exposition Engineers' Day, September 24, 1915." President Moore concluded with the hope that in the records of the engineering societies represented, mention would be made of these men who had honored the Exposition by their enthusiastic, conscientious and most efficient service.

PRESENTATION AT THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION OF COMMEMORATIVE MEDAL TO DR. JOHN A. BRASHEAR, PRESIDENT OF THE SOCIETY

The Panama-Pacific International Exposition presented a commemorative medal to Dr. John A. Brashear, as Pennsylvania's most notable citizen, at a ceremonial held in the Court of Abundance, on Wednesday, September 22, which day had been designated by the President of the Exposition, Charles C. Moore, as Brashear Day.

Colonel A. G. Hetherington, Director of Art, Pennsylvania Commission, took the chair and opened the proceedings with these remarks:

We are assembled here for the purpose of honoring a Pennsylvanian, who has been chosen as one of the most beloved, if not the most beloved, of the men of our state. He comes here representing nine millions of people. He has been honored all over the world, but the greetings that have been given to him are nothing, because he has, with his great genius, journeyed throughout the Heavens, with his illimitable space. He has within him the heart of a child and the agility of a boy, both physically and mentally. After

chief of construction, W. O. WATERS, superintendent of building construction; GUY L. BAYLEY, chief mechanical and electrical engineer; A. H. MARKWART, HARRIS, CHARLES C. MOORE, president of the Exposition; JOHN A. BRITTON, vice-president; CARL S. HERMAN; DR. F. J. V. SKIFF, director in chief; DR. WATSON, U. S. N.; CHARLES WARREN HUNT; HOWARD H. HOLMES, consulting engineer of the Exposition.

INTERNATIONAL EXPOSITION, SEPTEMBER 24, 1915

the presentation of the Commemorative Medal to him by Director Brown you will hear him speak. I will not detain you longer, and thank you for coming here to see our great Pennsylvania.

FRANK S. BROWN, Director of the Exposition, in behalf of President Moore, then presented the medal to Doctor Brashear, saying in part:

It is my great pleasure and high privilege to welcome here to-day Pennsylvania's most distinguished citizen, and to pay tribute to the genius of the man who has made not only his own state, but the nation illustrious.

Doctor Brashear is a man whom all the world honors for his accomplishments and above all for that sweet courtesy and kindness of heart that has endeared him to his friends and to the people of Pennsylvania. When we consider his accomplishments and how he has made possible for those of us who walk on this earth to behold the wonders of the Heavens and to get our inspiration from the planets that are moving through infinite space, surely we can say that to Doctor Brashear may be applied George Eliot's attribute: "The world is but made better for his presence."

We of the Exposition feel that we owe a great debt of gratitude to the engineering profession and to those who have representatives in our councils here—a debt of gratitude we can never repay, because we owe to the engineering profession the rebuilding of the city of San Francisco. It was said, after that great destruction of our city, that it would take years merely to remove the ruins, and you who live here know that in less than three years the city was practically rebuilt. It was said also that it was impossible to build the Panama Canal; in fact, as long ago as 1534 the first Panama Canal Commission appointed by the King of Spain reported to the King that there were not men enough and money enough in any nation in the world to undertake such a great accomplishment!

So we of the Exposition, we of California, and we of this nation want to honor our distinguished citizens, such as Doctor Brashear, feeling that in doing this we are honoring and glorifying the nation itself. We delight in honoring the citizens whom our great commonwealth has selected as its

foremost citizen; a man of accomplishment; a man whose sole purpose has been for the benefiting by his life the human race; a man who, without hope of reward or thought of reward, has consecrated his life to the work of uplifting humanity in order that the world might be improved by his presence.

So, in behalf of the Board of Directors of this great Exposition, it is my high privilege to-day to present to Doctor Brashear this bronze medal, typifying as it does the efforts of the human race for more than four centuries in the development of the civilization on the western coast, the efforts of the people of the United States in the completion of the Panama Canal that made possible the linking of all the world together, the energies of the people of San Francisco in the rebuilding of their city, and last, but not least, the building of this magnificent Exposition, which commemorates the achievements of such men as Doctor Brashear and the men of the engineering profession, and so, Doctor, I ask that you accept in behalf of the President and Board of Directors of the Panama-Pacific International Exposition this bronze medal, carrying with it our love, our gratitude, and our appreciation of what you have done for this nation.

Doctor Brashear, in accepting the medal, said he could not conceive why the State of Pennsylvania had gone into the polling mill and selected a mechanic as its leading citizen, when it had such men as Russell Conwell and John Wanamaker. He continued:

I must, however, say a few words of appreciation of the very kindly address that our good friend has given us in presenting me this medal. His words of praise are far more than I deserve, and far more than I shall be able to acknowledge in my response.

What I best love to say is that, although we may be great engineers, great scientific men or women, but whatever we are, it is our duty to have something else to do, as our good friend Mr. Brown has said, for the uplift and betterment of humanity, and the man or woman who cannot leave a record of having done something of the kind for the world, has lived in vain.

"It may be only a glad good morning
As we pass along the way,
But it will leave a ray of sunshine
Over the live-long day."

I want everybody to go from this place and forget me, but think of the other fellow, whom you can help out of the shadow into the sunlight of this old world. You can all do something. There is a greater accomplishment than that performed by our good friend Brown and his associates in the construction of these magnificent Exposition buildings—a greater work than we engineers and you officials have done in your calling—a greater work than the building of the Panama Canal, which has connected the two oceans. It is ours to break down the conditions that are damning this old world of ours by war, by affliction, by suffering, and by death. You and I can help to do it, every one of us. Let us all, whether we get medals or not, do what we can to make this old round world run smoother on its bearings, by pouring the oil of joy upon them rather than the spirit of heaviness.

COLONEL HETHERINGTON said there was no doubt that the Governor of California would be glad to be there, if it were possible, but he had sent a representative. He then introduced Mr. Arthur Arlett.

Mr. Arlett, speaking for the State of California, then addressed the company:

Of course, representing for the moment the State of California, any man with the heart and spirit and vision of this, our honor guest, is counted as one with us; for if there is one thing that we have been trying to establish in this commonwealth in these later years it is this—that the thing of supreme value in all the world is human personality and that that which transcends all other things, talent, finance, commercial greatness, is the human spirit. But with such a man as this, we say as men in California we find in you a fellow worker and a wondrous leader in our great task. To say a word or two, which might be formal, but which cannot really be so in this presence, I wish to say on behalf of our Governor, and as far as I may on behalf of the people of the State, that to this man who so thoroughly typifies that old and wonderful truth that "A child shall lead them" and has demonstrated to us that the surest sign of greatness is simplicity—to this man then we desire to render what homage we may. He feels a sentiment too great for words; he finds, I am sure, that our hearts' desire breaks through and escapes as with true fellowship, beyond any phrase, and beyond any word that human lips can utter.

R. L. COUNTRYMAN, a former citizen of Pennsylvania but resident in California, then spoke:

Pennsylvania has sent from its great borders men and women to preach patriotism and brotherly love, the brotherly love that is so highly typified by the great city of Philadelphia. We people of Pennsylvania, who have left that state for various reasons, retain our admiration and respect for it. We may love California, we may love the Pacific Coast, but still we may also love Pennsylvania.

Doctor Brashear has many accomplishments. His connection with the scientific world has been such that he has been elected into almost all of the renowned societies in the world as an honorary member or as an active member. He is a practical man; in other words, he calls himself a "greasy mechanic." He is a Doctor of Science. It seems also that he has literary accomplishments. He is a scientist—that has been recognized by all the scientific societies in the world. In addition to that, the one thing that most appeals to me in the Doctor is his ability as a maker of astronomical instruments. They say he can make the finest instruments of any man on the face of the earth; and any man who can bring to us the stellar system, so that we may understand the why and wherefore of life, is certainly entitled to be honored by any people.

I remember Professor Bernard, who was formerly at Lick Observatory, taking me to the observatory on the hill when he was in San Francisco, and fixing a clock and glass so that at a quarter of an instant

after eight o'clock I would see a certain star. I watched the clock and the star appeared on time. There was no question of delay, there was no question of any lack of ability to reach conclusions. Now, why is this system so perfect? That is the thing that the great astronomers, the men of science, are trying to determine for us to-day and to my mind the highest accomplishment, the greatest ability, is shown in the capacity of the various men who are studying and enabling us to study the solar system to ascertain the effect and cause of it.

We believe that the scientist should be encouraged, that the man who can tell us the mysteries of this system, star for star, and planet for planet, is the man whom we should want to revere; and so to-day, as Pennsylvanians, we are proud to say that we honor the great son of that state who is here to-day, representative of our great Keystone State. We feel his thoughtful way is leading men on upward to better things, and that the great state of Pennsylvania has reason to be proud that it can name as its most useful citizen, as its most distinguished citizen, the honored guest of this occasion.

1 JAMES HARTNESS, Past-President, Am.Soc.M.E.
2 WORCESTER R. WARNER, Past-President, Am.Soc.M.E.
3 WILLIAM GERRY MORGAN, M.D., Washington, D. C.
4 ANDREASE SWASEY, Past-President, Am.Soc.M.E.
5 JOHN A. BRASHEAR, President, Am.Soc.M.E.
6 CHARLES BURCKHALTER, Director, Chabot Observatory, Oakland, Cal.

GROUP OF NOTABLE MEN AT THE INTERNATIONAL ENGINEERING CONGRESS

THE APPROACHING ANNUAL MEETING

All the Annual Meeting papers, with the exception of three or four in the hands of committees, are being printed in pamphlet form for advance distribution. Copies of any or all papers will be sent to any member in advance of the meeting upon request. The prospects are that pamphlet papers will be available early and that members who are intending to contribute written discussions will have ample time to prepare them.

The program of the meeting is now completed except in one or two minor particulars and is announced below. This early announcement will enable members living at distant points and who intend to come to the meeting to make their arrangements in advance.

The social features of the meeting will be the reception and the dinner and dance for members and their ladies and guests, and the smoker for members.

One business meeting and seven professional sessions will be held and on one afternoon, excursions have been arranged to points of exceptional interest.

This is the seventieth general meeting of the Society and the thirty-sixth annual convention. It is hoped that all members will find it possible to attend and take part in the deliberations, and so contribute to the success of the meeting. The attendance at annual meetings has been increasing steadily, and last year the attendance was a record one.

PROGRAM

Tuesday Evening, December 7

Opening Session: Address by Dr. John A. Brashear, President of the Society.

Reception by the Society to the President, President-elect, ladies, members and guests.

Wednesday Morning, December 8

BUSINESS MEETING

Reports of the Council and Standing Committees. Constitutional Amendments. Announcement of Report of Power Test Committee. New Business.

Immediately following the business meeting, the Society will honor the memory of the late Dr. Frederick W. Taylor, Past-President. The proceedings will consist of a report by a special committee appointed by the President to represent the Society at the Taylor Memorial Meeting held in Philadelphia on October 22 under the auspices of the Society to Promote the Science of Management.

PROFESSIONAL SESSION

Papers to be presented by title only

GAS PRODUCERS WITH BY-PRODUCT RECOVERY, Arthur H. Lynn

THE APPLICATION OF ENGINEERING METHODS TO THE PROBLEMS OF THE EXECUTIVE, DIRECTOR AND TRUSTEE, Hollis Godfrey, Mem. Am. Soc. M. E.

MODERN ELECTRIC ELEVATOR AND ELEVATOR PROBLEMS, David Lindquist

These three foregoing papers contributed by the New York local committee

TURBINES VS. ENGINES IN UNITS OF SMALL CAPACITIES, J. S. Barstow

Contributed by the Philadelphia local committee

THE CONNORS CREEK PLANT OF THE DETROIT EDISON COMPANY, C. F. Hirschfeld, Jun. Am. Soc. M. E.

Contributed by the Buffalo local committee

PROPORTIONING CHIMNEYS ON A GAS BASIS, A. L. Menzies, Assoc. Mem. Am. Soc. M. E.

The foregoing papers which are to be presented by title will be distributed at the meeting in pamphlet form, and written discussion upon them solicited for publication in *The Journal*. There will be no opportunity for oral discussion of these papers.

STEAM POWER

Papers to be presented by abstract

DESIGN OF FIRE TUBE BOILERS AND STEAM DRUMS, F. W. Dean, Mem. Am. Soc. M. E.

HIGHER STEAM PRESSURES, Robert Cramer, Mem. Am. Soc. M. E.

A NOVEL METHOD OF HANDLING BOILERS TO PREVENT CORROSION AND SCALE, Allen H. Babcock

This paper in preliminary form was presented before the San Francisco local section, December, 1914

Wednesday Afternoon

SIMULTANEOUS SESSIONS

RAILROAD

Papers contributed by the Sub-Committee on Railroads

OPERATION OF PARALLEL AND RADIAL AXLES OF A LOCOMOTIVE BY A SINGLE SET OF CYLINDERS, Abatole Mallet, Hon. Mem. Am. Soc. M. E.

FOUR-WHEEL TRUCKS FOR PASSENGER CARS, Roy V. Wright, Mem. Am. Soc. M. E.

Other papers to be announced

TEXTILE

Papers contributed by the Sub-Committee on Textiles

HEATING BY FORCED CIRCULATION OF HOT WATER IN TEXTILE MILLS, Albert G. Duncan, Mem. Am. Soc. M. E.

Other papers to be announced

MACHINE SHOP

Papers contributed by the Sub-Committee on Machine Shop Practice

ELECTRIC OPERATION AND AUTOMATIC ELECTRIC CONTROL FOR MACHINE TOOLS, L. C. Brooks, Jun. Am. Soc. M. E.

REPORT ON CODE FOR ABRASIVE WHEELS

Other papers to be announced

Wednesday Evening

SMOKER

A departure will be made from the usual Wednesday evening lecture, by holding a Smoker in the rooms of the Society, to which all members are invited. This will be a get-together, get-acquainted meeting, in charge of the New York local committee, to which every member is invited for a social evening and a good time.

Thursday Morning, December 9

SIMULTANEOUS SESSIONS

POWER PLANT

THE HEAT INSULATING PROPERTIES OF COMMERCIAL STEAM PIPE COVERING, L. B. McMillan, Jun. Am. Soc. M. E.

PERFORMANCE AND DESIGN OF HIGH VACUUM SURFACE CONDENSERS, Geo. H. Gibson, Mem. Am. Soc. M. E., and Paul A. Babel, Jun. Am. Soc. M. E.

CIRCULATION IN HORIZONTAL WATER TUBE BOILERS. Paul A. Bancel, Jun. Am. Soc. M. E.

UNIQUE HYDRAULIC POWER PLANT AT THE HENRY FORD FARMS, Mark A. Replogle, Mem. Am. Soc. M. E.

MISCELLANEOUS

THE FLOW OF AIR THROUGH THIN-PLATE ORIFICES, Ernest O. Hickstein, Jun. Am. Soc. M. E.

This paper is the Junior Prize paper for 1915, and bears the further distinction of being the first paper to receive a prize from The American Society of Mechanical Engineers. A fund for Junior and Student prizes was recently established by a member of the Society.

ELASTICITY AND STRENGTH OF STONEWARE AND PORCELAIN. James E. Boyd

Contributed by the Research Committee

FOUNDATIONS, Charles T. Main, Mem. Am. Soc. M. E.

Contributed by the Sub-Committee on Industrial Building

OIL ENGINE VAPORIZER PROPORTIONS, Louis Illmer, Mem. Am. Soc. M. E.

Thursday Afternoon

This afternoon is left free for excursions. Instead of providing for a large number of excursions, as in previous years, the Local Committee has arranged for a few of exceptional interest which it is expected large groups of members and guests will attend.

Thursday Evening

Annual Reunion, Dinner and Dance at Hotel Astor.

Friday Morning, December 10

INDUSTRIAL SAFETY

Papers are in preparation, of which definite announcement will be made later, on the following subjects:

Safety Standards in Industrial Establishments

Modern Movement for Safety from Standpoint of Manufacturer

Methods of Reducing Accidents Through Coöperative Movements with Workmen

Compulsory Compensation for Accidents by Law

This session is under the direction of the Sub-Committee of Protection to Industrial Workers.

ABSTRACTS OF PAPERS

Abstracts of the papers to be presented at the Annual Meeting will appear in this and the next numbers of The Journal. These abstracts, while brief, will serve to furnish members with an adequate idea of the contents of the papers, and will be of assistance to any member in selecting those papers of particular interest to him and to the discussion of which he might desire to contribute.

GAS PRODUCERS WITH BY-PRODUCT RECOVERY

By ARTHUR H. LYNN

The object of this paper is to present an historical resumé of the development of the by-product producer gas industry in Europe.

As far back as 1883, Young and Bielby in England claimed to recover in the form of ammonia from 60 to 70 per cent of the total nitrogen in the fuel, and although their retort was heated from the outside instead of the air and steam blast be-

ing superheated this ammonia recovery is not far short of what we realize to-day.

Two years later Dr. Mond first put into commercial practice his process of gasifying fuel by means of steam and air and simultaneously recovering the ammonia. Up to 1897 Dr. Mond was constantly endeavoring to improve his process, but after that time he appeared to be satisfied with its design.

E. J. Duff, whose interests were afterwards amalgamated with Dr. Mond's into the Power-Gas Corporation, brought out a plant which differed from the Mond plant only in the design of the superheater. Several large Duff plants were constructed.

The next improvements were claimed by Crossley Bros., who introduced a plant in which the washing and cooling of the gases, as well as the condensing of the water vapor and the absorption of the ammonia took place in one and the same apparatus.

The author replaced the irksome towers of these early plants by a system of vertical washers. He substituted steel for lead in the parts of the ammonia absorbing apparatus, and made improvements in the removal of dust by adopting a cyclonic dust separator of somewhat special design.

In the gas producer itself, mechanical agitation in the fuel and ash zones and mechanical ash removal were introduced. Modifications of this system applied to ammonia recovery plants resulted in a vastly increased volume of air and steam, a deeper fuel bed, superheating of the blast, increased blast pressure and consequently deeper water lute.

Ammonia recovery plants have been applied for power as well as for heating purposes. Power gas and by-products are now regularly produced from peat containing up to 60 per cent water.

APPLICATION OF ENGINEERING METHODS TO THE PROBLEMS OF THE EXECUTIVE. DIRECTOR AND TRUSTEE

By DR. HOLLIS GODFREY, MEM. AM. SOC. M. E.

This paper is an endeavor to determine the methods by which the service of a consulting engineer may be made of greatest value to the executive of a corporation, or to a board of directors or trustees, during the interregnum in an executive office. After an experience of several years, the author has found the following method of value.

- (a) The defining, on the basis of facts shown by engineering study, of the policies of a business.
- (b) The expression in simple usable form of the definitions obtained.
- (c) Construction on the basis of studies made.

Money saving and money making, time saving and improvement of service are all intimately connected with proper definition and expression of facts about a business.

The consulting engineer who is serving a corporation should present to the executive a general preliminary coöperative study of the field to determine what lines are most worthy of study, a coöperative determination of what facts should be known about these lines, a careful collection and intensive study of the facts existing in the lines chosen, the translation of the facts collected in the light of their relation to the other departments of the business, the expression of the facts studied and a method for the constructive use of the facts obtained.

The coöperative engineering adviser to an executive must be able to distinguish clearly between records which are vital to the future policies of a business and those which are merely historical; the past in industry as a determinant for policies is of value only as it is vitally concerned with the future. He must omit many engineering refinements, to avoid doing work that costs more than it is worth. He must check his work with the practical needs and limitations of the business. He must keep abreast of the "best of the art." He must have a wide acquaintance with professional men and must be able to bring to bear upon the problem before him the best that science and industry have yet produced.

MODERN ELECTRIC ELEVATOR AND ELEVATOR PROBLEMS

BY DAVID LINDQUIST

This paper is an interesting treatise on the problem of the modern electric elevator in its bearing upon the construction of tall buildings in the large cities. It is a clear analysis of building elevator practice in general and points out the steps in the development of electric elevator practice, wherein the traction type of electric elevator has come to replace all of the earlier highly developed hydraulic types. The possibility of locating the traction elevator machine at the top of the hatchway has, it is shown, been a powerful factor in its development.

The problems that have attended the development of the traction electric type are outlined, including those of roping, counterweight and rope compensation, construction of the motor, armature shaft bearings, power consumption, and safety devices. The electrical achievement in the design of a motor capable of operating efficiently at 60 r.p.m. and less, is, of course, responsible for this radical design of elevator machine, but incidentally, this form of design affords unusual opportunities for interesting and very efficient methods of braking and control.

In the consideration of the power consumption of this type, careful attention is given to the character of the service handled in numerous specific cases. The requirements for elevator service in tall buildings in the large cities are, in fact, so exacting that only by the most effective control, as is afforded by a traction type of machine, can satisfactory service be given; the traction design is shown to lend itself readily to quick starting and stopping, and rapid rates of travel between floors.

The author concludes with detailed reference to a new form of safety device which has been worked out in connection with the application of elevators of this type to the high-speed, high-rise service. The requirements for safety devices in this class of service are pointed out, and the interesting constructional details, by means of which the various requirements are fulfilled, are described.

TURBINES VS ENGINES IN UNITS OF SMALL CAPACITIES

BY J. S. BARSTOW

The author limits the term "units of small capacities" to steam turbines and engines of less than 500 h.p. capacity, and an effort is made to point out the fields within this range where the small turbine is of conceded superiority, and likewise the other fields wherein the engine must hold sway.

Within the past few years, the practicability of the small turbine has been definitely established, and with it results are shown that in many cases exceed those obtainable with the engine.

In comparing the two types of prime movers, the author considers them with regard to: *a.* Speed conditions and limitations; *b.* Steam pressure and temperature conditions; *c.* Power capacity of turbines; *d.* Relative space requirements; *e.* Use or application of the exhaust steam; *f.* Available cooling water supply; *g.* Operating conditions; *h.* Relative cost of complete installations.

The paper concludes with a classification under the headings: direct connected units, condensing; direct connected units, non-condensing; and geared units, indicating the classes of service under which each of the two types is more applicable.

THE CONNORS CREEK PLANT OF THE DETROIT EDISON COMPANY

BY C. F. HIRSHFELD, MEM. AM. SOC. M. E.

This paper is a discussion of the power plant problem of the Detroit Edison Company in the City of Detroit, whose phenomenal growth as a result of an unusual industrial development has brought interesting questions to the company. It became evident in 1912 that greatly increased power producing capacity would soon be required, and after an extended consideration of the requirements of the distribution system in its relation to the present large plants at Delray, it was decided to construct a large new additional power plant at the opposite end of the city. In connection with this decision, interesting statistics are presented relative to the growth of population of the city, the increase in the annual power output, and of the load factor.

The reasons that decided the interesting layout at the Connors Creek site are discussed, and the opportunities for introduction of interesting features of design are outlined. The arrangement for coal and ash handling, and the construction for future development were effective in bringing about a most unusual design of plant and equipment.

Special mention is made of the large boiler units and their layout in relation to the turbine units operated from them; two of these boiler units are installed to supply each of the 25,000 k. v. a. turbo-generator units. The details of the steam piping and other auxiliaries are described, with special reference to the jet condenser equipment used in connection with steam driven auxiliaries for feed water heating. The paper concludes with a description of the electrical system with its switching and control equipment.

PROPORTIONING CHIMNEYS ON A GAS BASIS

BY A. L. MENZIN, ASSOC-MEM. AM. SOC. M. E.

This paper reviews the subject of calculating the proportions of chimneys, taking into account the increasing tendency to operate boilers at higher overloads, the attention being given to balling as a factor in improving boiler performance and the efforts to improve the efficiency of combustion, resulting in a reduction of the volume of gases to be removed.

It considers mathematical expressions for deducing the effective draft and height of a chimney; for determining the maximum draft produced by a chimney; for finding the draft

required to produce a change of velocity of the chimney gases; for calculating the loss of draft due to sudden enlargement of gas passage; for expressing the friction loss in breeching and chimney, and for arriving at the draft required at the boiler damper. It describes the method of converting boiler horse power into gas volume to enable the utilization of the principles discussed, and illustrates the application of the formulae and data for calculating chimneys on a gas basis by working out a practical problem in detail.

DESIGN OF FIRE TUBE BOILERS AND STEAM DRUMS

By F. W. DEAN, MEM. AM. SOC. M. E.

This paper considers what makes steam boilers dangerous and how certain parts should be designed in order to make them safe. It is intended as an extension of the Society's work, through its Boiler Code Committee, in devising rules for the construction and care of steam boilers.

The great and usual cause of weakness in boilers is the bending of some part first one way and then the other with the application and removal of pressure, causing cracks. This part is usually the longitudinal joint, and the lap form of this joint has been a prolific cause of explosions. Butt joints, properly designed, have practically eliminated this cause.

A detail of boiler making which needs more careful attention is that of bending plates.

Boiler head braces should be supported so as to prevent movement in any direction, instead of merely supporting the weight.

In riveting, the best practice is undoubtedly to drill all holes from the solid.

A conical course in the outside firebox of a vertical boiler is preferable to a reversed flange. The latter bends backward and forward under pressure, and is liable to crack.

Dished heads "breathe" with changes of pressure, causing them finally to crack round the flange. Such heads should be made thinner and braced like flat heads.

Tight brickwork is desirable to prevent the leak of air, with its harmful effect on draft and economy.

Horizontal return tubular boilers, no matter what their length or size, should be supported at no more than four points. The three-point principle of supporting boilers is the best, and this effect can be obtained and yet have the boiler held up at four points by connecting two points to an equalizing lever working on a pin passing through overhead supporting beams.

HIGHER STEAM PRESSURES

By ROBERT CRAMER, MEM. AM. SOC. M. E.

Theoretical considerations, based on the laws of thermodynamics, point out that the economy of steam engines and turbines could be further improved by increasing steam pressures over those now commonly in use. The probable gains for different conditions are given graphically and in tabular form.

Practical difficulties arising from the problems of design and operation of engines, turbines, boilers, and fittings are broadly discussed and the conclusion is reached that higher steam pressures should prove practical and profitable.

OPERATION OF PARALLEL AND RADIAL AXLES OF A LOCOMOTIVE BY A SINGLE SET OF CYLINDERS

By ANATOLE MALLET, HON. MEM. AM. SOC. M. E.

The author undertakes in the paper an analysis of the many attempts that have been made for the transmission of power to convergent axles of locomotives from a single set of steam cylinders. In the discussion, the mechanisms on records for this purpose are divided into two classes: *first*, those involving elements having rotary motion, and *second*, those involving elements having reciprocating motion. In the first class it develops that there are several examples on record that utilized gear transmissions of interesting form, while another group made use of endless chains; a third group has driving mechanism consisting of universal joint connections between trucks, a form of construction most applied in the United States.

Of the class utilizing reciprocating motion, many interesting examples are quoted. These are divided in the following groups: Those operating connecting rods located in the longitudinal axis of the engine; those coupling by oscillating levers or equalizers; those using free axles; those using external connecting rods of which the length varies with the convergence of the axle.

FOUR-WHEEL TRUCKS FOR PASSENGER CARS

By ROY V. WRIGHT, MEM. AM. SOC. M. E.

There are four important factors which demand attention in the designing of trucks for railway passenger cars. These are, in the order of their importance, safety, smooth riding, minimum weight and low cost of maintenance. The Pennsylvania Railroad uses four-wheel trucks for carrying much heavier passenger cars than do most of the other railroads in this country. The paper deals with the development of the modern steel four-wheel truck for passenger service on that system, giving particular attention to the degree to which it meets the above requirements.

ELECTRIC OPERATION AND AUTOMATIC ELECTRIC CONTROL FOR MACHINE TOOLS

By L. C. BROOKS, JUN. AM. SOC. M. E.

In the early application of electric motors to machine tools, the motors were started by hand starters. While there are a number of cases in which these starters are still more applicable, we have reached the time when automatic starters, remote controlled, are the most suitable.

Some of the advantages of automatic control are: The operating switch is easily attached to the machine and the main panel may be located at a distant point. The starting time of the machines is automatically regulated to suit the load conditions on the motor. Accurate stopping points are obtained by "dynamic braking."

All panels should be provided with fool-proof enclosing cases, meeting applicable safety-first requirements, for protecting the appliances from injury and the operator against accidental contact. All automatic starters and control apparatus should be provided with protection from low voltage on the line, also from excessive overload.

The three general types of automatic starters are *time element*, *counter E.M.F.* and *current limit*. Starters for small motors consist of line contactor, overload relay, field rheostat and connecting board. For larger motors, where one step of resistance is necessary, they include line switch and fuses, contactor, C. E. M. F. accelerating contactor and connection board. For still larger motors the latter is modified to accommodate the additional accelerating contactors.

At the present time, the problem of purely automatic control for general lathes has not been entirely solved, although lathes for a special class of work have been controlled with safety and efficiency. Automatic control equipment has been applied to boring mills, planers, and slotters.

Not the least important factor for a successfully operating electrically controlled machine is the motor. For small printing presses, ventilating fans, small machine tools, woodworking machines, etc., the shunt motor is applicable and for adjustable speed work it is suitable for planers, boring mills, heavy lathes, etc. The series motor should always have a certain friction load and is thus applicable to centrifugal pumps, cranes and hoists.

SAFETY CODE FOR THE USE AND CARE OF ABRASIVE WHEELS

During the year 1914 a committee of the National Machine Tool Builders' Association studied the question of a Safety Code for the Use and Care of Abrasive Wheels. This report was presented before the Worcester meeting of this association, following which representatives of abrasive wheel manufacturers conferred on the matter and made certain modifications, based in part on a tentative report on the subject by a special committee appointed by the State of Pennsylvania. The Sub-Committee on Machine Shop Practice of the American Society of Mechanical Engineers has considered this revised report and made further suggestions and now submits the code with these features added for discussion at the Machine Shop Session of the Annual Meeting.

THE HEAT INSULATING PROPERTIES OF COM- MERCIAL STEAM PIPE COVERINGS

By L. B. McMILLAN, JUN. AM. SOC. M. E.

While an enormous amount of effort has been expended in attempts to determine accurately the savings effected by the use of non-conducting coverings on steam pipes, little information is on hand regarding the efficiencies of pipe coverings in commercial use at the present time. Most of the early results of tests apply at only one temperature or two at most, and for one or two thicknesses; they are not applicable to modern conditions involving high superheat and thicker coverings.

The paper describes an investigation of the effect on heat losses of varying the temperature difference between pipe surface and air, between the limits of 0 and 500 deg. Fahr. Different thicknesses of material from 0 to 3 in. were tested and the laws confirmed. The drops in temperature from steam in a pipe to the inner and outer surfaces of the pipe wall under various conditions were accurately determined.

A new fact brought out was that the loss from any covered pipe is a function of the temperature difference between the surface of the covering and the surrounding air, and this

function is the same for all coverings having the same character of surface regardless of what the other properties of the covering may be, since the effects of these appear in the temperature difference. The value of this was determined for canvas covered surfaces, and a complete explanation of its significance is given.

While a careful study of conditions is necessary before a certain type of covering can be recommended for a certain type of work, the author hopes the data given in the paper will be of use to engineers in deciding upon covering material and in calculating heat losses in installations already in use.

CIRCULATION IN HORIZONTAL WATER TUBE BOILERS

By PAUL A. BANCEL, JUN. AM. SOC. M. E.

Flowing within a boiler under steam are two fluids, steam and water, and these have different velocities, the steam being said to "slip" through the water.

By considering the flow in a simple circuit, and citing experiments with the air lift, an example of such a circuit, the conditions favorable and otherwise to slip are revealed. These experiments indicate that slip and friction change the relation of volume to velocity to nearly the square root law.

In an actual water tube boiler, with the circuit more complex, it is shown that with the bottom tubes discharging a light weight mixture and with slip and eddies due to the large area of the header and resistance due to the restricted area and abrupt turn at the entrance to the drum, there is a choking of circulation, particularly in the bottom tubes where it is most needed.

Constructions with circulation flues in the front header as means of improving circulation are shown.

Photographs illustrating the circulation, both front and rear, in the header of a model boiler with glass cover plates and with different types of headers and relative positions of boiler, fire and gas passages, show strikingly the conditions obtaining at loads up to 500 per cent.

UNIQUE HYDRAULIC POWER PLANT AT THE HENRY FORD FARMS

By MARK A. REPLOGLE, MEM. AM. SOC. M. E.

The hydraulic power plant recently constructed at the Henry Ford Farms contains two turbines designed to develop 85 h.p. each under 8 ft. head at 110 r.p.m., with electric generators. Current is supplied for light, heat and power for the residence, the village pumping station, and for the miscellaneous requirements of the farms.

There were unusual flowage conditions due in part to high water at certain periods and in part to back water from the Great Lakes. These conditions were met, and a uniform delivery of power secured, through the adoption of unusual features in the installation of the turbines. These features in the main consist of so-called turbine discharge accelerators built into the tailrace of each turbine, whereby an added head-effect is produced and the flow through the turbine increased. The accelerator consists of a form of draft tube into which the turbine discharges and into which, also, water from the upper level is discharged through a feeder terminating in an annular ring surrounding the outlet of the

discharge tube from the turbine. The water from the feeder increases the flow—accentuates the flow through the draft tube. Experiments conducted at this plant indicate: (1) That the turbines can be speeded for full head at low water conditions; (2) that if water is available, the power capacity of the turbine can be practically doubled at the same head; (2) that if water is available the unit can develop its normal rated power at one-half head; (4) that considerable power can be furnished at normal speed when the working head is less than 25 per cent of the normal head. All of this may be accomplished at good efficiency.

THE FLOW OF AIR THROUGH THIN-PLATE ORIFICES

By ERNEST O. HICKSTEIN, JUN. AM. SOC. M. E.

This paper describes in some detail the methods used by a large pipe-line company in the Mid-Continental field in the calibrating of its orifice meter discs.

An orifice meter consists of a calibrated disc in a pipe-line, with pressure line connections running to two indicating or recording gages; one gage is for measuring the static pressure of the flowing gas and the second the differential drop of pressure across the orifice disc.

The paper deduces the following general formula for the flow of air through an orifice disc:

$$Q_o = C_g \sqrt{h P_i}$$

where

Q_o = volume at standard temperature and pressure

C_g = so-called "gas constant," found experimentally

h = differential in in. of water

P_i = pressure at inlet of orifice

It then describes in detail tests made on orifice meters at Joplin, Mo., to determine the velocity coefficients of 8 and 10-in. orifice meters. The discs were calibrated against the displacement of air from an old artificial gas holder, with lower lift capacity of 110,000 cu. ft. Preliminary tests were run to determine leakage from the holder and changes of volume in holder with temperature variation.

About 160 tests were then run on 8 and 10-in. meters; a summary of the results is given in the paper.

Nearly fifty orifice meters have been installed and are now in operation, their deliveries of high pressure gas being calculated from the air constants found in the Joplin tests. It is confidently expected that, with some little further study and experimenting, the orifice meter will take its place among the most reliable methods of measuring natural gas in large quantities.

ELASTICITY AND STRENGTH OF STONEWARE AND PORCELAIN

By JAMES E. BOYD

This investigation was undertaken at the suggestion of Ralph D. Mershon, Mem. Am. Soc. M. E., who expressed the belief that exact knowledge of the form of the stress-strain diagrams of clay products in tension and compression would make possible the design of insulators of greater mechanical strength and more definite factor of safety.

The pieces tested were porcelain pieces from the General Electric Co., stoneware pieces from the Keasbey Stoneware Works and also some porcelain pieces made in the Department of Ceramics of the Ohio State University.

All measurements of deformation were made by means of a lever extenso-meter, a Brown and Sharpe micrometer being used to measure the movement of the longer arm.

A form of grip was developed which eliminates the eccentricity of loading of the best pieces due to lack of perfect symmetry in the heads of the pieces. With all grips, however, it was found that the test pieces broke at the head, so the form of the pieces was modified.

The results of the tests indicate that the modulus of elasticity of stoneware and porcelain is practically the same in tension as in compression. The modulus of elasticity of porcelain is about 10,000,000 while that of stoneware ranges from 6,000,000 to 9,000,000, depending on the material. The compressive strength of porcelain and high stoneware in a column 16 in. long and 1 in. in diameter is about 20,000 lb. per sq. in. The stress-strain diagram is practically straight up to 7000 lb. per sq. in. The tensile strength of porcelain is above 3000 lb. per sq. in. The tensile strength of stoneware ranges from above 1100 to above 2200 lb. per sq. in.

FOUNDATIONS

By CHAS. T. MAIN, MEM. AM. SOC. M. E.

It is of great importance to support all structures on a stratum of soil below silt or peat. If the structure is to be a heavy one, it is necessary to use piles. Buildings which are to contain moving machinery or delicate instruments would naturally require piles with fairly large factors of safety.

Soils are tested as to their suitability for foundations by making wash borings. Test pits furnish an opportunity of observing the character of the soil. If the structure is to be a heavy one, some of the borings should be carried to bed rock and dry samples of the soil taken every few feet.

Work on foundations consists of excavation of earth or rock, including shoring, sheet piling, or coffer dams, and a structure of stone, concrete, brick or timber at the bottom of the excavation, including bearing piles.

Where the depth of good bottom is too great to be reached economically by the foundations, it becomes necessary to use piles, the values of the factor of safety and working or ultimate strength of which are all to be fixed to suit the class of structure to be supported.

The structures most commonly used at the bottom of the excavation are concrete, stone laid in cement mortar or bedded rock, stone laid with outside joints pointed and then grouted full, and stones laid dry.

OIL ENGINE VAPORIZER PROPORTIONS

By LOUIS ILLMER, MEM. AM. SOC. M. E.

This paper is the synopsis of a research made some time ago to determine the proper proportions of hot bulbs for oil engines of the Hornsby-Akroyd type, and largely extended of late to include high compression oil engine vaporizers.

The vaporizer of low compression oil engines is heated by the gases of combustion and provides a hot surface for the double purpose of evaporating the heavy mineral oils in the fuel-oil and of maintaining the confined mixture charge at a temperature high enough to enable self-ignition to be induced.

The one simple relation suitable for design purposes is that of vaporizer volume to piston displacement. The other design factors depend upon more involved relations and cen-

ter about the average temperature attained by the unjacketed cap portion of the vaporizer wall. By analysis, the average full load cap temperature of a Hornsby-Akroyd engine is found to be about 1275 deg. Fahr. The total vaporizer volume should be about 0.3 of the piston displacement or about 2/3 the clearance volume.

When a Hornsby-Akroyd engine is running on 1:3 to 1:2 of the full load oil, the hot products of combustion may be expected to raise the temperature of the entire vaporizer content to 750 deg. Fahr. ignition temperature. Below this critical point, the temperature head is reduced to such an extent that the cap no longer keeps the vaporizer content sufficiently preheated to reach the ignition temperature at the end of the compression temperature. The limit of efficiency and m.e.p. of the engine are so restricted as to make it quite cumbersome in sizes of 50 h.p. and upward. This limitation may be overcome by injecting the fuel-oil, by means of highly compressed air, near the end of the compression stroke.

High compression oil engines operating at less than 135 lb. per sq. in. compression pressure should have their vaporizer volume made equal to the entire clearance space, while in high compression engines the vaporizer volume may be made proportionally smaller; at about 400 lb. compression the vaporizer may be dispensed with. The moderate preheating requirements of the high compression engine allow self-ignition to be attained without maintaining the vaporizer cap at full red heat; this reduces internal strains in the cap casting.

COUNCIL NOTES

At the meeting of the Council on October 8, 1915, it was voted to approve the following recommendations with regard to the Society's publications, as made by the Publication Committee:

Transactions

(1) That the publication of the annual volume of Transactions be continued.

(2) That it be published in the same size and binding as heretofore.

(3) That it shall contain subject to the approval of the Publication Committee, all of the papers and discussions presented at regular meetings of the Society (not including section meetings), and technical reports of Committees; and shall contain a syllabus of each paper, summarizing the essential facts and conclusions.

(4) That it shall contain all the papers and discussions presented at section meetings which in the opinion of the Publication Committee are of sufficient merit.

Revises

(1) That additional revised copies of the papers and discussion be printed and bound in pamphlet form at the earliest practicable date.

A charge will be made for such pamphlets.

Advance Papers

(1) That papers for the meetings of the Society be printed in pamphlet form in advance as heretofore, and be sent to members gratis upon request, a notice of these papers with syllabi being printed in The Journal one month before meetings.

The Journal

(1) That The Journal be published monthly as heretofore, but with the view of making it a semi-monthly or a weekly as soon as the amount of matter to be handled requires it and funds for that purpose are available.

(2) That the size of The Journal shall for the present remain as it now is.

(3) That The Journal shall contain:

(a) All of the papers and discussions presented at regular meetings of the Society, preferably in sub-

stantially complete form, or adequately abstracted, according to the character of the paper, as soon after the meetings as possible.

(b) Papers, or abstracts, with discussion, presented at meetings of Local Sections.

(c) Announcements and reports upon Society affairs and incidents, employment bulletin, library notes, personal notes, etc.

(d) Department for contributed discussions on papers previously published, or new matter.

(e) Members correspondence department, including suggestions on Society affairs.

(f) Review of world's technical press.

(g) Review of technical books, by experts selected by the Committee.

The Committee adopt as a policy that the Editor shall cooperate with the author to present all papers and discussions as concisely as possible, consistent with clearness and completeness. This not only adds to the utility of the paper, but will make possible the publication of more papers in complete form. An abstract should be done by the author. The Editor will cooperate towards securing uniformity.

The paper, "Flow of Air Through Thin Plate Orifices," by Ernest O. Hickstein, Jun. Am. Soc. M. E., was approved for the Junior Prize.

No award of the Student Prize was made this year.

W. L. R. Emmet and Spencer Miller were reported elected as the representatives of the Society on the Naval Consulting Board. The appointment by the President of W. R. Dunn to represent the Society at the inauguration of John Henry MacCracken as President of Lafayette College was reported. Wm. H. Wiley was appointed delegate of the Society to the convention of the Atlantic Deeper Waterways Association.

The Boiler Code Committee was empowered to make rulings where inquiries are made respecting constructions not covered by the Code, and to interpret any parts of the Code, but the action on all rulings made by the Committee was ordered reported to the Council for approval before being issued.

The appointment as a Committee on Sections in Los Angeles of W. W. Smith, *Chairman*, W. A. E. Noble, *Vice-Chairman*, Ford W. Harris, *Secretary*, O. J. Root and Frederick C. Finkle was approved. Leigh Hunt was appointed on the Increase of Membership Committee, in place of H. Struckmann, resigned.

The substitution of a Smoker for the usual Wednesday evening address at the Annual Meeting was authorized.

CALVIN W. RICE, *Secretary*.

REPORT OF THE NOMINATING COMMITTEE

As previously announced in The Journal, the Nominating Committee has reported the following names as candidates for the offices indicated:

For President:

D. S. JACOBUS, New York

For Vice-Presidents:

WM. B. JACKSON, Chicago, Ill.

J. SELLERS BANCROFT, Philadelphia, Pa.

JULIAN KENNEDY, Pittsburgh, Pa.

For Managers:

JOHN H. BARR, New York
JOHN A. STEVENS, Lowell, Mass.
H. de B. PARSONS, New York

For Treasurer:

WM. H. WILEY, New York

CONFERENCE OF LOCAL SECTIONS AT THE ANNUAL MEETING

The great success attending the Conference of Local Sections at the Spring Meeting has prompted the Committee on Sections to arrange for such meetings of Section representatives to be one of the regular features at the Annual or Spring Meetings. Many items of considerable importance were developed at the last Spring Meeting and delegates were present from San Francisco, Atlanta, Milwaukee, Chicago, New York,

Walter Rautenstrach, Columbia Univ., New York, N. Y.
D. Robert Yarnall, Chestnut Hill, Philadelphia, Pa.

STUDENT BRANCH CONFERENCE

Representatives of various Student Branches of the Society held a meeting at the last Annual Meeting and so much benefit was derived by those who attended that it was voted to make the Student Branch Conference one of the regular features of the Annual Meeting.

Invitations have been issued therefore to all Student Branches to appoint delegates to the Conference at the coming Annual Meeting. Some of the colleges are at such a great distance that it will probably be impossible for the Student Branch to send an undergraduate representative. It is hoped that those Branches who cannot send an undergraduate will arrange for a graduate or one of the faculty to represent them.

MEDALLION PRESENTED BY THE PANAMA-PACIFIC INTERNATIONAL EXPOSITION TO
THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, SEPTEMBER 16, 1915

Providence, Philadelphia, Cleveland, Worcester, Birmingham, etc. All Sections were not represented however, and it has been arranged therefore to pay the traveling expenses of an officer of every Section in the United States.

Preferably the delegate should be the Chairman or Secretary, if either of them may find it possible to attend, or the member of the local committee conversant with its activities. By this action it is hoped to have every Section represented by a delegate who can officially and comprehensively present the views and requirements of the members in their locality.

Invitations have been extended to several centers where no Section now exists to authorize some member to participate at the Conference with a view to establishing a Section.

It is hoped by this means to develop thoroughly and put on an efficient basis this very important phase of the Society's activities. Information may be obtained by addressing any member of the Committee on Sections.

Elliott H. Whitlock, *Chairman*, 1506 West 112th St.,
Cleveland, Ohio
W. F. M. Goss, Univ. of Illinois, Urbana, Ill.

CORRECTION

LABORATORY FOR LIQUID METERS

In a letter dated September 28, Geo. H. Gibson points out an error in his discussion of the paper on Laboratory for Liquid Flow Meters by W. S. Giele, published in Vol. 36 of Transactions, page 757. In place of the first paragraph of his discussion, the following paragraph should be substituted:

It is ordinarily assumed that the flow over a V-notch weir increases as the $5/2$ power of the head, that is according to the formula $F = CH^{5/2}$. This assumption possibly simplifies calculations and in the absence of facilities for testing V-notch weirs under all conditions and heads, manufacturers of flow recorders for use with such weirs have used it in the laying out of the cams of the recorders, by means of which the rise of the float measuring the head on the weir is translated into the motion of the pen recording the flow.

NEW EDITION OF THE BOILER CODE

A second edition of the Boiler Code which contains a comprehensive index to the volume has been issued. The index is divided into two parts, one a general index to the complete rules and the other containing sectional indexes to the parts referring to New Installations of Power Boilers, New Installations of Heating Boilers, and Existing Installations.

NAVAL ADVISORY COUNCIL AND NAVAL CONSULTING BOARD

The historic photograph on this page was taken at the first meeting of the Naval Advisory Council and the civilian Naval Consulting Board at Washington on October 6, 1915. This is the first time that civil-

practically all chiefs of departments; they welcomed the formation and organization of the civilian Board, the latter to constitute a non-partisan research body to assist in passing upon inventions and ideas submitted to the Navy.

At the first meeting of the joint Boards, Thomas A.

ians, representing the public through the national engineering societies, have been called into convention with officers of the Government to discuss problems of the Navy. The photograph shows the Secretary of the Navy, Hon. Josephus Daniels, seated beside Thomas A. Edison, and the departmental associates of the former in convention with the country's distinguished and leading civilian inventors and engineers.

The members of the Naval Advisory Council are

Edison was elected Chairman of the civilian Board; Peter Cooper Hewitt, First Vice-Chairman; William L. Saunders, Second Vice-Chairman; and Thomas Robins, Secretary. The entire civilian Board is being resolved into committees.

Secretary Daniels appointed Rear Admirals Taylor, Strauss and Griffin as a Committee on Inventions in the Navy Department, and this committee is to appoint an officer to receive all suggestions from in-

ventors. Promising inventions will be forwarded by this committee to each member of the civilian Board, and each is expected to express an opinion respecting the feasibility of the invention or to mark it "no report." The Boards recommended a plan to establish a research laboratory to cost eventually \$5,000,000, and the Secretary of the Navy will ask Congress for an appropriation of \$1,000,000 to begin work. The essentials of the plan for this laboratory in which it is proposed to submit to actual test all seemingly meritorious naval inventions are as follows:

1. The laboratory to be located on tidewater of sufficient depth to permit a dreadnought to come to the dock; near but not in a large city, so supplies may be easily obtained and where labor is obtainable.
2. The laboratory to be of complete equipment, to enable working models to be made and tested to destruction. There should be: A pattern shop; a brass foundry; a cast iron and cast steel foundry; machine shops for large and small work; sheet metal shop; forge shop for small and large work; marine railway large enough to build experimental submarines of 1,500 tons; wood-working shops; chemical laboratory; physical laboratory; optical grinding department, &c.; motion picture developing and printing department; complete drafting rooms; electrical laboratory and wireless laboratory; mechanical laboratory and testing machines; explosives laboratory, removed from main laboratory.
3. The building to be of modern concrete construction, with metal sills and doors, wire glass windows, ample fire protection, &c.
4. A naval officer of rank to be in charge. Under him naval heads of broad experience in laboratory methods and science in general—practical as well as theoretical men. Under them staffs of civilian experimenters, chemists, physicists, &c. Each subhead to have his corps of assistants, and shop facilities. There is to be at least two, and possibly three shifts of men.
5. Secrecy to be the governing factor.
6. Facilities to exist for enabling the inventor to assist in the development of the idea he has presented, provided he is a practical man.

The next meeting of the Boards will take place on November 4 in New York City.

MEMORIAL SERVICE TO PAST-PRESIDENT FREDERICK WINSLOW TAYLOR

A remarkable service was held in Philadelphia Friday evening, October 22nd, in Houston Hall of University of Philadelphia, under the auspices of the Society to Promote the Science of Management. The hall was filled to overflowing with many of the leaders in management, representatives of Philadelphia's citizens and the following official participants in the meeting:

The provost of the University, Edgar Fahs Smith; the Mayor of Philadelphia, Rudolph Blankenburg; President of the Society to Promote the Science of Management, Dr. Harlow S. Person; Louis D. Brandeis; Past-President of this Society, James M. Dodge;

three former associates of Mr. Taylor, all members of this Society, H. L. Gantt, Carl G. Barth and Sanford E. Thompson; and Colonel Vignal, military attaché at the French Embassy, who read a letter from Henri Le Chatelier. A full account of these addresses will be presented to the Society at the annual meeting in December by a Committee that represented the Society at the exercises, consisting of Henry R. Towne, F. R. Hutton, John R. Freeman and Oberlin Smith.

On Saturday the party met at Boxley, near Highland Station, Philadelphia, the former home of Mr. Taylor and was shown about the house and grounds.

ENDORSEMENT OF THE BOILER CODE BY THE NATIONAL ELECTRIC LIGHT ASSOCIATION

An important coöperative movement in the introduction of the Boiler Code into legislative channels in the various states, is the recognition given at a recent meeting of the National Electric Light Association in approving the action of the American Uniform Boiler Law Society in its work of securing the general adoption of the Boiler Code recently formulated by a Committee of The American Society of Mechanical Engineers. The National Electric Light Association has appointed John Hunter, member of the Council of the Am. Soc. M. E., as its representative to serve on the executive committee of the American Uniform Boiler Law Society, who is expected to be particularly able in securing the coöperation of member companies of the National Electric Light Association in any state where the adoption of the Code is being agitated.

COLLEGE REUNION NIGHT AT THE ANNUAL MEETING

During the last few years a very pleasing arrangement has been made whereby those attending the Annual Meeting who are graduates of one of the technical colleges have enjoyed a reunion of their Alumni Association. This year College Reunion Night will occur on Friday, December 10, and arrangements are under way for reunions of alumni of the following colleges: Brown University, Cornell University, Massachusetts Institute of Technology, Polytechnic Institute of Brooklyn, Purdue University, Rensselaer Polytechnic Institute, State University of Kentucky, Stevens Institute of Technology, Worcester Polytechnic Institute and Yale University.

The Society will be pleased to place at the disposal of any college alumni organization the facilities of the office or publications to develop reunions in connection with the coming Annual Meeting, and such organizations are invited to correspond with the Secretary. The large number of engineering graduates visiting New York at that time of the year offers an excellent opportunity for successful reunions.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON DECEMBER 1, 1915

Members are requested to scrutinize with the utmost care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their ages would qualify them and not with regard to professional qualifications, i. e., the ages of those under the first heading would place them under either Member, Associate or Associate-Member; those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential, and is solely for the good of the Society, which it is the duty of every member to promote. The candidates will be balloted upon by the Council unless objection is received by December 1, 1915.

SAN FRANCISCO MEETING

THE two papers presented at the first session, September 16, of the September meeting of the Society held at San Francisco in connection with the Panama-Pacific International Exposition and the International Engineering Congress were published in the October issue of *The Journal*. The three remaining papers, by Prof. W. H. Adams; A. H. Goldingham and Prof. G. H. Marx and L. E. Cutler, presented at the second session, September 17, are published in this issue. The paper by Professor Adams outlines very completely Diesel engine design and tendencies and considers the operation of this type of engine with various fuels. Mr. Goldingham's paper embraces heavy oil engines, both of the Diesel and hot surface types, and includes new cost data. Professor Marx and Mr. Cutler's paper on gear teeth throws light upon the question of allowable stress for modern cut cast-iron gear teeth.

THE DIESEL ENGINE AND ITS APPLICATIONS IN SOUTHERN CALIFORNIA

BY WALTER H. ADAMS, PASADENA, CAL.

Member of the Society

DIESEL secured his first patents in 1893, and brought out his first successful engine in 1897, at the Augsburg Works in Germany, and since the latter date the use of the Diesel engine has been increasing steadily, especially in Europe. Several well-known steam engine manufacturers in the United States today have begun the manufacture of Diesel engines, thus showing a growing demand in this country for such a prime mover. There are comparatively few Diesel engines in the United States at present, the total horsepower in use being just over 100,000, but the number is increasing rapidly every month.

Diesel's original patent described the action of his engine as follows: (a) The highest temperature is that due to the compression of air only and this may be regulated by making the compression the desired amount. (b) Into this air is introduced the fuel, gradually, in a finely divided state and in such quantity that the burning offsets the cooling due to the expansion as the piston moves forward.

This was the original idea of Diesel, namely, a supply of heat at constant temperature. Such a supply would fulfill one of our thermodynamic conditions for maximum efficiency—a supply of heat at a constant maximum temperature. Diesel's engine in practice did not give this desired result, so he modified his statement to cover an increase in temperature during the admission of the fuel, this increase in temperature taking place at constant pressure. This is the condition of the Diesel engine today, as closely as it is possible for the actual engine to meet the ideal conditions.

The difference between the Diesel engine cycle and that of the standard form of internal combustion engine (Otto) is shown in Fig. 1. In the Otto cycle there is compression from *A* to *B*; ignition and burning at constant volume from *B* to *C*; expansion from *C* to *D*; and rejection of heat to the exhaust, at constant volume, from *D* to *A*. (It makes no difference in the ideal diagram whether the engine is 2- or 4-cycle.) In the Diesel engine there is corresponding com-

pression from *A* to *B*; then burning at constant pressure from *B* to *C*; expansion from *C* to *D* and exhaust at constant volume from *D* to *A*. In the Otto cycle there is an explosion while the volume remains constant, thus increasing the pressure and temperature; in the Diesel cycle there is burning at constant pressure while the volume and temperature increase.

The expressions for the thermal efficiency of the ideal cycles are also shown in Fig. 1, and curves plotted from these equations are given in Fig. 2. The most interesting thing to observe from these curves is that, for corresponding pressures at the end of compression, the Diesel engine has the lower thermal efficiency. This is offset by the fact that in the Otto engine the limit of compression pressures is 80 to 200 lb. per sq. in., while in the Diesel engine the compression may be carried as high as desired. The reasons for this are that in the Otto engine the fuel is compressed with the air, and pre-ignition will take place if the compression is carried too high, due to increase of temperature with increase of pressure. In the Diesel engine, air only is compressed and the temperature may rise as high as desired without danger of pre-ignition. The temperatures due to compression are shown in Fig. 3. At a pressure of 500 to 550 lb. per sq. in. the temperature is about 1000 deg. Fahr., and if fuel in a finely divided condition is introduced into air at this temperature, it will take fire and burn without any special ignition apparatus.

Fig. 3 was calculated for an adiabatic compression. There is considerable discussion as to what is the correct exponent for this curve as it varies with different engines; therefore the ideal curve is used. The actual temperatures would agree approximately, as the new charge of air is heated above 100 deg. Fahr. by the hot cylinder walls and by mixing with the burnt gases in the clearance space. This makes a higher initial temperature although the compression curve is flatter than the ideal.

High compression is possible with the Diesel engine with corresponding gain in efficiency, and at the same time there is more complete combustion of the fuel because of the finely divided state in which it is forced into the cylinder. The maximum possible efficiency for the Otto engine is 52 per cent for blast furnace gas and 44 per cent for a motor car engine. Against this there is 57 per cent efficiency for the Diesel engine, a gain of 29 per cent over the motor car engine and 11 per cent over the blast furnace gas engine. If the Otto engine could have the same compression, it would be a better engine than the Diesel engine.

Presented at the Panama-Pacific International Exposition meeting, San Francisco, September 1915, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Contributed by the Los Angeles Section. The paper may be obtained in pamphlet form; price 10 cents to members, 20 cents to non-members.

This question may be asked: Why cannot the efficiency of the Diesel engine be further increased by higher compression than 500 to 550 lb. per sq. in.? This is possible in the ideal engine, but experience has shown that 600 lb. per sq. in. is the highest allowable pressure in the actual engine. For pressures above that amount, the increased size of the parts of the engine increases friction and cost above any gain in theoretical efficiency. Changes in the Diesel engine will have to be more along the line of reduced cost and simpler design rather than better economy.

2-CYCLE AND 4-CYCLE INTERNAL COMBUSTION ENGINES

The difference between the 2-cycle and 4-cycle types of internal combustion engine is in design and construction and not in theory.

In the 2-cycle engine there is expansion of the burnt gases until near the end of the stroke; then exhaust begins and almost simultaneously there is admission of either air and fuel or air alone at another part of the cylinder—this ad-

FIG. 1 COMPARISON OF CYCLES AND THERMAL EFFICIENCIES

mission taking place under slight pressure. The burnt gases are forced out by the fresh charge, the piston moves back and compression takes place. This gives one working stroke for every revolution, just as in a single-acting steam engine. The necessary compression of the inlet air is supplied by the slight compression produced by the piston in an enclosed crank case (cheap engines), or is produced by a separate scavenging air compressor, as in all 2-cycle Diesel engines. In this type the pressure of the air is not carried to more than 4 to 8 lb. per sq. in. above atmospheric.

In the 4-cycle type there are ignition and expansion until the end of the stroke. Then the exhaust valve opens and remains open until the piston has moved back, thus allowing the piston to expel the burnt gases. The exhaust valve closes and the admission valve opens, remaining open while the piston moves forward to draw in a fresh charge. It then closes and compression takes place. This complete cycle requires two revolutions of the engine and in practice necessitates a large flywheel or a multiple-cylinder engine if the speed is to be kept constant.

There are advantages and disadvantages for both types applied to Diesel engines. The 2-cycle type gives almost twice as much power for the same size of cylinder, as it has two working strokes for one in the 4-cycle. (Actual

value is 170 to 180 per cent.) This means less weight, space and first cost. As usually constructed, the piston acts as its own valve and so air inlet and exhaust valves are not required. (This is not true of some of the better class of 2-cycle Diesel engines, as will be explained later.) In marine work the reduction in number of valves makes it easier to reverse a 2-cycle engine. The use of the 2-cycle type has also made large units possible, and 1200 h.p. per cylinder in a single-acting engine has been built.

On the other hand there is to be said for the 4-cycle type of Diesel engine:

a It is older than the 2-cycle type and so has become a more stable construction

FIG. 2 COMPARISON OF EFFICIENCIES, OTTO AND DIESEL ENGINES

FIG. 3 DIESEL ENGINE COMPRESSION TEMPERATURES

- b It gives better fuel economy, as expansion can be carried to the end of the stroke and no power is required for the scavenging pump. The gain is about 10 per cent
- c The mean temperature is lower. There is more time to remove the heat and not so much heat to remove per unit of cylinder surface. (In a 2-cycle engine 90,000 B.t.u. per hour has to be removed for every square foot of cylinder surface. In 4-cycle engines the figure is 40,000 B.t.u. In an ordinary water-tube boiler working at 300 per cent of rating, it is 10,000 B.t.u.)
- d The valve gear runs at one-half the speed of the main shaft
- e In the high speed 2-cycle engine, it has been difficult to get the burnt gases out of the cylinder in the short time available, so that such engines have not been quite as successful as 4-cycle engines.

The tendency in this country and abroad is to use 4-cycle engines up to from 700 to 1000 h.p. and above that 2-cycle. This is due to the reduced first cost of the 2-cycle type in

the large sizes and the excessive diameter of cylinder required in large 4-cycle engines. As progress is made in design, the 2-cycle type may supersede the 4-cycle, but this is not evident at present in the smaller sizes.

APPLICATIONS OF THE DIESEL ENGINE

The Diesel engine is in use today in almost all places where a steam engine or turbine might be used. Its starting torque is poor and it should run at a constant speed, although this may be varied to some extent. The rated load decreases as the altitude at which the engine operates is increased.

The engine is being employed for propelling ships of over 400 ft. in length and 9000 tons in cargo capacity, at a speed of about $11\frac{1}{2}$ knots; such ships are twin-screw and have engines of 1600 b.h.p., developed in 6 cylinders. The engine has not been used for high speed passenger ships. It has been used in many sailing vessels to provide auxiliary power in calm weather. It has been used in submarines, and the Craig Shipbuilding Company is now building for the United States Government some submarines which are to be equipped with Busch-Sulzer Diesel engines.

One locomotive equipped with Diesel engines has been built in Europe, but it was large, clumsy and not very successful. Diesel locomotives will not compete with steam locomotives at present. For isolated plant or central station service the Diesel engine is well adapted, if several units are installed so that each unit will work near its rated load without a heavy overload under all conditions of load factor.

The Diesel engine gives excellent service when installed as a pumping engine. It can be used for all kinds of factory service just as well as the steam engine. The reasons why it is not adopted more extensively in this country are probably:

- 1 The availability of cheap fuel has prevented a demand for an expensive first cost prime mover that will give decreased operating cost
- 2 American manufacturers have been slow to take up the manufacture and introduction of these engines
- 3 Engines giving satisfactory service have only been made in Europe within the last five years
- 4 A Diesel engine requires extreme care in manufacture and in adjustment, particularly of the fuel valve
- 5 The engine cannot be operated without careful supervision when the cleaning and adjusting are going on
- 6 Some prejudice exists against all forms of internal combustion engines due to the multiplicity of causes that may prevent their starting
- 7 Oil must be used as fuel, and the cost may vary within wide limits
- 8 Innate conservatism of the human race makes it slow to adopt a new method or machine until others have tried it.

DESIGN CHARACTERISTICS OF DIESEL ENGINES

It is my intention to discuss design characteristics in a general way, summing up the present situation, rather than to describe details of the various types. (Since the preparation of this paper was commenced, an excellent article¹ on the design of the Diesel engine has been published in *THE JOURNAL*.)

¹Vol. 36, December, 1911, page 420. Recent Developments in the Manufacture of the Diesel Engine, H. R. Setz.

At present, engines are manufactured in this country in both the horizontal and vertical types. One to four cylinders are used in the horizontal and one to six cylinders in the vertical engines. The favorite size of the latter is two to four cylinders.

The horsepower per cylinder ranges from 30 to 250, with size of cylinder varying from 12 to 21 in. The stroke bore ratio is about 1.25. (In December one manufacturer announced a 4-cylinder vertical engine of 2500 b.h.p.).

The smallest Diesel engine (dimensions of cylinder) that the author finds any record of is a $6\frac{3}{4}$ by $8\frac{5}{8}$ in., 2-cycle, 4-cylinder engine, developing 110 b.h.p. at 550 r.p.m. The largest engine is a 32.2 by 39.4 in., 2-cycle, single-cylinder

FIG. 4. COMPARISON OF HEAT BALANCES

engine, developing 1250 b.h.p. at 150 r.p.m., m.e.p. 106 lb. per sq. in. This latter is an experimental engine built by Carels Bros. in Belgium. If such an engine were built with 8 cylinders, it would have an output of 10,000 b.h.p., which would compare favorably with a steam turbine, if the space occupied be neglected.

The engines built in the United States are all comparatively slow speed, ranging from 150 to 300 r.p.m., with piston speed of 600 to 900 ft. per minute. A few high speed marine engines have speeds as high as 480 r.p.m. In Europe, before the war started, there was being developed a line of high speed engines with a speed of 550 r.p.m. for submarines and such work. The highest commercial speed in use at present is 350 to 400 r.p.m.

All engines, except one make, are single-acting. (One manufacturer reports the making of a double-acting engine, but I should judge that this has not been tried out thoroughly.) In Europe several firms were experimenting on a double-acting engine; the trouble experienced in this type is in cooling the cylinder and piston and keeping the stuffing boxes tight.

All engines in this country, except two makes, embody trunk pistons without crossheads. In Europe several marine

types use a crosshead, but all others employ the trunk piston. The crosshead takes the wear produced by the angular thrust of the connecting rod.

Valves and Valve Gear. There is necessarily considerable difference in the design of valves and gear of the 2-cycle and 4-cycle types. As the piston acts as its own valve in the high speed 2-cycle type, there are only two valves in the cylinder head—the fuel valve and air starting valve. In the better slow speed 2-cycle engines there are 7 valves in the cylinder head; these are 4 scavenging valves, 1 fuel valve,

1 air valve and 1 safety valve. (There are no American engines with 4 scavenging valves in the cylinder head.)

In an engine with a 21 by 30 in. cylinder, the amount of oil per stroke at rated load is only 0.4 cu. in. When it is remembered that this oil must be introduced in the form of a very fine spray in a time of about 1/40 sec., and that the regulation of the amount of oil is the only method of governing the engine, it is easy to imagine the troubles of the early operators and designers. The fuel valve must not clog or fill with gum and must always operate correctly. The designs of the manufacturers vary in detail, but the underlying principle is the same. The fuel is pumped into a chamber surrounding the valve by a pump whose stroke is controlled by the governor; this chamber forms a labyrinth passage. Air under a pressure of 800 to 1000 lb. per sq. in. is admitted in back of the oil and forces the latter into the cylinder in the form of a fine spray. The valve is controlled by a cam, opening about 1 per cent before the end of the compression stroke and remaining open from about 8 to 10 per cent of the working stroke.

In most of the present engines, the oil is forced into the valve passages against the air pressure, thus requiring a strong oil pump. Several manufacturers have adopted the method of pumping the oil into a restricted passage between the air valve and the cylinder during the suction stroke of the engine, where it remains until the air valve opens and it is forced into the cylinder. This arrangement reduces the work of pumping. The relative merits of the two types are under discussion today. So far as the author can find out the low pressure type seems to give the best satisfaction with California oils. At least the manufacturers using this type say they can use any grade of oil, while the manufacturers of the high pressure type like to specify a minimum grade of oil that they can use.

The remainder of the design of the Diesel engine follows gas engine design quite closely, with generally more massive and careful construction. It is discussed more fully in the paper quoted above.

Air Compressor. The air used for spraying the oil into the cylinder is supplied by a 2- or 3-stage air compressor. The pressure required for the spray is 800 to 1100 lb. per sq. in., depending mainly upon the kind of oil used, but also to some extent on the load under which the engine is working. The amount of this air is estimated to be from 16 to 34 cu. ft. of free air per b.h.p. per hour. The power required for operating the compressor is about 4 to 7 per cent of the total power developed by the engine. The compressor is usually made an integral part of the engine, and is driven by a crank forged on the crank shaft. In a few cases it is driven by a belt from the engine or by a motor.

Scavenging Pump. In the 2-cycle engines a special scavenging pump is used for driving the burnt gases out of the cylinder. This is usually made the low pressure stage of the air compressor. As previously mentioned, the scavenging air is controlled by the piston or by scavenging valves in the cylinder head. This latter type gives the best scavenging, as the air sweeps through the cylinder from the head end, and passes out through ports placed around the circumference at the crank end. There is a large gain in economy and power due to using this scavenging air in the 2-cycle engine, because of better combustion, but it is not necessary in the 4-cycle engine.

The air is supplied at a pressure of 4 to 8 lb. per sq. in. above atmosphere. The volume of this air is from 1.2 to 1.8 times the cylinder volume. The power required for the pump

FIG. 5 RESULTS OF TESTS ON 3-CYL. LYONS-ATLAS DIESEL ENGINE

1 starting air valve and 1 safety valve. (There are no American engines with 4 scavenging valves in the cylinder head.)

The 4-cycle engine must have at least 4 valves, namely, suction, exhaust, fuel and starting valves. The safety valve is often combined with the air starting valve. In most engines the valves are all placed in the head of the cylinder, but in a few types the suction and exhaust valves are placed on its circumference.

The material used for cylinder walls, liners, and heads is cast iron. A few engines have been equipped with cast steel heads, but these did not prove satisfactory and cast iron has been substituted.

Fuel Valve. The fuel valve in the Diesel engine is the most delicate part of it. Even when the engine is fully loaded, this valve moves only a few hundredths of an inch.

is approximately 4 per cent of the output of the engine.

Governing. The governing is by a governor which regulates the amount of fuel supplied to the engine. The governor holds the suction valve of the fuel pump open for a portion of the forcing stroke, or regulates the length of the stroke of the pump, or varies the clearance of the pump. Each manufacturer employs a different method for governing, but all methods in use seem to give a close regulation. If the engine has more than one cylinder, each cylinder must have its own pump and all pumps must be under the control of the governor. As far as the author knows, no one has attempted to distribute the oil to the various cylinders after it leaves a common fuel pump.

The regulation is well under 3 per cent in all types, and, if necessary, some manufacturers are willing to guarantee much closer regulation. All engines, except the single cylinder types, will give close enough regulation for operation of all electrical machinery. The overload capacity of the Diesel engine is small when compared to turbines as it is only about 10 to 15 per cent.

Water Cooling. The cylinders and cylinder heads of all Diesel engines must be watercooled, and in the larger sizes the pistons must be cooled also. The amount of water required is about 3 to 9 gal. per b.h.p. per hour, depending upon the temperature rise which is allowed. With a temperature rise of 70 deg. Fahr. the amount of water will be about 3 to 4 gallons. The maximum temperature of the cooling water is kept about 130 to 140 deg. Fahr., although it may rise to as high as 180 deg. Fahr. if the water contains no impurities that will precipitate at this temperature. The heat carried away in the cooling water is about 2500 to 3000 B.t.u. per b.h.p. per hour.

FUELS

Any fuel that will burn without leaving an ash or residue, either due to incomplete combustion or due to unburnable material in the fuel, may be used in a Diesel engine. Attempts have been made to introduce pulverized coal into the cylinder of the engine, but these have not as yet been successful. Gasoline, kerosene and the light distillates need not be considered as fuel for the Diesel engine as they can be used to better advantage elsewhere.

There is left crude oil, low-grade distillates and the coal tar products. The last have not been used to any great extent in this country.

Crude oil which is free from sand and water can be used as fuel, even if it contains as much as 50 per cent asphaltum. Owing to the scarcity of gasoline, today practically all crude oil has the gasoline content removed before it is sold for fuel, so that all fuel oil is "topped" oil.

On the Pacific Coast we are not interested in the Eastern oils, but I would like to say that when used in Diesel engines these have given better satisfaction than the Western oils. The California oils have been tried on the manufacturers' testing floors in the Eastern states, and all reports that the author has received indicate that they have been satisfactory. But, at the same time, the statement is made that the tests have not been continued for more than 6 to 7 days as the supply of the special oil becomes exhausted. After such tests the condition of the engine is always reported to be excellent. The objections that the author has heard against the Western crude oils are these: Viscous and sluggish, high sulphur content, high water content, and high in ash.

A viscous and sluggish oil can be heated by the cooling water as it leaves the engine, or by the hot exhaust gases, until it becomes fluid. It can then be pumped as well as any oil. When such an oil is employed kerosene should be used to start up with and for a few minutes before shutting down, so as to clean out all the heavy oil from the piping and pumps.

The high sulphur content oil is more dangerous, as it burns to sulphur dioxide which tends to cause corrosion of the piston and cylinder, the valves and valve seats and the exhaust pipe. The maximum amount of sulphur that can be allowed seems to be about 2 to 4 per cent.

Water in the oil will decrease the heating value and cut down the amount of fuel delivered to the cylinder. If the water comes in "slugs" it will cause the engine to run irregularly. "Topped" oil will not contain much water, as it will be removed during the topping process. Most manufacturers specify an oil containing less than 1 to 2 per cent of water.

The ash is of considerable importance as it tends to remain in the cylinder, causing cutting of the walls, the valves and the valve seats. This makes the maintenance

FIG. 6 INDICATOR CARDS FROM 3-CYL. LYONS-ATLAS DIESEL ENGINE

charges high. The Eastern paraffine base oils can be cleaned much easier than the Western asphaltum base oils. In the latter the asphalt collects around the sand particles, and it is impossible to separate them except by heating the oil and straining it while hot.

Some engines are working today on Western oils being sold in the market as boiler fuel oil. The Diesel engine located on the Jameson ranch at Corona, Cal., is now running on 24 to 26 deg. Beaumé Santa Fé tops bought for the smudge pots. The oil costs 60 cents per barrel, f. o. b. Los Angeles. This engine has been run for more than 2 months without a shut-down. About a quart of coal oil was supplied twice a day to clean out the pump. The engine was run for 10 days on 18 deg. fuel oil then in use on a steam road roller in Corona, and the run was stopped at the end of that period, as the supply of that particular fuel was exhausted.

The Lyons-Atlas Company sold a 600 b.h.p. engine to the Hawaiian Commercial and Sugar Company on the guarantee of 710 hours operation out of 720 per month on 14 to 18 deg. California oil, then in use under the company's boilers in the Hawaiian Islands. The engine was tested at the factory under the supervision of the company's engineer, was paid for, and then shipped through the Panama Canal to the Islands. The test consisted of a 48-hour preliminary run on Eastern oil and then a 144-hour (6 day) continuous run at

rated load on the California oil. At the end of the run, the valves and the heads were examined and no evidence of any deposit was found. A 120 h.p. 4-cycle engine has been running for 6 months, 24 hours a day, without a stop, in San Antonio, Texas. The fuel was a 20-deg. Texas oil. There are numerous other examples of engines on this coast, but not using California oils. Many engines are in operation in Texas, New Mexico and Arizona using Texas and Mexican oils.

ECONOMY AND EFFICIENCY

The economy of the Diesel engine is the best of all present engines. Fig. 4 shows the heat balance for a 4-cycle Diesel

Curves starting lower left hand corner show total fuel

FIG. 7 DIESEL ENGINE, COMPARISON OF FUELS

engine, and also for one of the latest large steam turbine plants. In preparing this heat balance for the Diesel engine, a mechanical efficiency of 77 per cent was assumed and the thermal efficiency of an actual engine, as shown by test, was used as a basis for the remainder. The distribution of waste heat between exhaust and cooling water for this engine varies, so that an equal distribution was assumed.

The heat balance of the turbine plant is a composite heat balance based upon an oil-fired boiler and a turbine generator unit, using the best steam figure that I have record of; 95 per cent is allowed for the efficiency of the generator and 95 per cent for the mechanical efficiency of the turbine.

The author's idea in making this comparison is to show the best thermal efficiency in both types of prime movers, thus indicating the superiority of the Diesel engine as far as thermal efficiency is concerned. So far as is known, however, no steam turbine plant is operating today with an overall thermal efficiency quite as high as the 20 per cent shown.

The efficiency of the Diesel engine may be still further increased by utilizing the heat in the exhaust for making steam to run a steam turbine. Experiments are now being carried out in this direction, but the results are not yet good enough to indicate that this can be done in all cases. Experiments are also being made along the line of increasing

the temperature of the jacket water, so that this may be converted into steam which may be used.

Figs. 5 and 6 show respectively efficiency curves and indicator cards for a 3-cylinder Lyons-Atlas Diesel engine, using an Eastern oil. Fig. 5 shows clearly that from about 60 per cent to 120 per cent of the rated load the economy and thermal efficiency remain nearly constant. The mechanical efficiency tends to increase as the load increases. This factor is about 75 per cent at full load for a 4-cycle engine and 70 per cent for a 2-cycle engine. (This is due to the power required for the air compressor for the scavenging air.)

Fig. 7 shows the results of a series of tests on an engine, using various fuels. When the best grade of fuel indicated is used, the amount is about 0.4 lb. per b.h.p.-hr., while it does not exceed 0.5 lb. with the poorest grade at rated load.

The Diesel engine will work nearer to test conditions at all times than any other type of prime mover, as it is more independent of the operator and requires a good compression for ignition. The efficiency depends upon the compression; if

FIG. 8 COST OF DIESEL ENGINES, F.O.B. LOS ANGELES, CAL.

this latter drops due to valve trouble the engine will show it at once, as there will not be heat enough to ignite the fuel.

OPERATING AND DEPRECIATION

The amount of lubricating oil is stated to be about 0.01 pint per b.h.p. per hour, based on the rated load. The engine at Corona uses 3 quarts of oil every 24 hours to supply the loss. The load is about 35 h.p., while the rating of the engine is 65 h.p. This is at the rate of 0.008 pint per h.p. per hour.

One engineer can handle 1000 to 1500 horsepower per shift. The attendance consists in keeping the engine supplied with both fuel and lubricating oil and the minor work that there always is around a power plant. Operators and manufacturers say that it is necessary to examine the fuel valve and the exhaust valves periodically and clean them. The time interval for this depends upon the kind of fuel in use—it may be a week or several months.

The question of maintenance and depreciation is still an open one. The maintenance charges per year seem to average

about 1 per cent of the first cost of the engine. Very few manufacturers have yet had engines in service for any length of time, so that the life of the engine is still uncertain, although it is claimed to be longer than that of a steam engine. The Buelch-Sulzer Diesel Engine Company have two 225 b.h.p. engines installed in Texas which were put in over nine years ago; these have been operating on an average of 18 hours a day. The cylinders have never been rebored and now show very little wear and are as smooth and bright as glass. The same company also has a 225 b.h.p. engine in Illinois which has been working for 24 hours a day, 63½ days a week, for over 2½ years, with only two minor shut downs.

The following facts seem to be fairly well established:

FIG. 9 COMPARISON COST CURVES, STEAM TURBINE AND DIESEL ENGINE, 600 KW. MUNICIPAL LIGHTING PLANT

- 1 The Diesel engine can operate continuously for 6½ or more days out of seven
- 2 This can be kept up for long periods if a short interval is allowed for overhauling and minor repairs
- 3 The exhaust valves may give trouble by burning if the load is too large
- 4 The air compressor may give more trouble than the engine if it is not watched
- 5 Dirt in the oil will give trouble
- 6 Water in the oil will give trouble
- 7 The engine will not carry much more than its rated load for any length of time.

WEIGHTS AND COSTS

The weight of the Diesel engine per horsepower varies considerably, even for the same size of engine. Data supplied by the manufacturers in this country show that the weight per b.h.p. varies from 250 to 500 lb., with no uniformity, except that the higher-priced engines are the

		95 cents bbl.	\$1.50 bbl.
		95centsbbl.	\$1.50 bbl.
Fuel at 95 cents per bbl.	\$8,910	Fuel	\$2,790
Fixed charges 14 per cent	7,030	Fixed Charges	\$2,790
			\$4,410
Total	\$20,190	Total	\$17,620
			\$19,240
			\$17,120
			\$18,740

DISCUSSION OF THESE VALUES

Difference in first costs = \$73,300 - \$50,200 = \$23,100.
Diesel Engine Plant costs 46 per cent more

Difference in operating costs,

(a) \$20,190 - \$17,120 = \$3,070. Net saving per year = \$3,070.

(b) \$20,190 - \$18,740 = \$1,450. Net saving per year = \$1,450.

Conclusion: Difference in yearly cost is so small that no definite conclusion can be drawn.

Each plant should be investigated carefully before the type of equipment is decided upon.

heavier. In an issue of London *ENGINEERING* during 1914, the statement was made that in European practice the weight had been reduced to 62 lb., but this was an exception.

The cost of the engine is hard to determine, as it varies so much and manufacturers do not like to supply cost data. The

price increases directly with size of engine from \$6000 for a 75 h.p. engine to about \$48,000 for a 1000 h.p. engine. The price of a small Diesel engine is prohibitive and that for large engines of several thousand horsepower does not go much below \$45 per horsepower. Curves of costs plotted from data supplied by several manufacturers are given in Fig. 8.

COST OF A SMALL PLANT

Table 1 shows a comparison of the cost of steam turbine and Diesel engine plants, 600 kw. The plants are suppositions, but the cost figures given can be considered as approximately correct. They show that the Diesel may enter into serious competition with the steam plant when the load factor is better than 25 per cent. The Diesel engine will not replace the steam plant until much more definite figures are secured regarding the life of the former.

As the yearly load factor is increased the Diesel engine will show a saving in total operating cost due to the saving in fuel. In the steam plant the fuel item is the largest single item of expense, with the fixed charges next. In the Diesel plant the fixed charges are the largest single item, with the remainder of the operating cost about equally divided between fuel and labor, water, etc.

The items under first cost of the two plants are only approximately correct, as the author had no personal data available and had to depend upon published results which did not check with one another. The output per barrel of oil is based upon published yearly reports of both Diesel and steam plants. The steam plant is located in California while the Diesel plant is in Texas. The distilled oil cost was purposely placed high, so as to indicate the showing that a Diesel engine could make in competition with a steam plant, even if it was handicapped with a high price of suitable oil. As we are not interested in comparison of coal and oil as fuels, no attempt has been made to show such. The items under operating cost were taken from a published report of a Diesel plant in Texas, where wages are low in comparison to those in California. In the turbine plant about the same conditions of operating have been assumed, as the total of the items listed under lubrication and miscellaneous are small.

In Fig. 9 showing cost curves are plotted the yearly costs for the plants against price of oil per barrel. This shows graphically the effect of the price of oil on the total operating cost. By projecting from the total operating cost curve of the steam turbine plant to the corresponding curve for the Diesel plant, a comparison may be secured for any price of oil. For example, assume the price of boiler fuel oil to be 75 cents and engine oil to be 90 cents per barrel. Then the turbine plant will cost \$18,400 per year, and the Diesel plant \$17,500 per year. When the price of oil is 53 cents per barrel, the yearly cost will be about the same for both plants.

On account of the lack of data relative to the life of the Diesel engine, the same fixed charges, namely, 6 per cent depreciation, 6 per cent interest and 2 per cent insurance and taxes, have been assumed alike for both plants for comparison.

The item of life of the Diesel engine is open for discussion, but no one can yet say definitely what the life of the Diesel engine, properly taken care of, is going to be, as none of our successful plants have been in operation long enough to give the answer.

THE HEAVY OIL ENGINE, ITS PRESENT STATUS AND FUTURE DEVELOPMENT

BY A. H. GOLDINGHAM, NEW YORK

Member of the Society

SINCE the oil engine was invented, about 1870, rapid progress has been made with it. This is best demonstrated by reference to the indicator diagrams, Figs. 1 to 8, taken from engines built during the past twenty-seven years.

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Fig. 6

Fig. 8

INDICATOR DIAGRAMS SHOWING PROGRESS IN OIL ENGINES SINCE 1888

The first diagram was taken from a Priestman oil engine, 1888 type, cylinder 10 $\frac{3}{4}$ in. diameter, stroke 14 in., 160 r.p.m. The initial pressure was 125 lb. per sq. in., exhaust pressure 24 lb., compression pressure 20 lb. and m.e.p. 44 lb. The b.h.p. developed was 8.4, using fuel with a heating value of 19,000 B.t.u. and specific gravity 0.853. The fuel consumption was 1.05 lb. per b.h.p.-hr. and the thermal efficiency 12.8 per cent. All these figures represent average conditions.

Author's Note: The distillate engine largely in operation in the Pacific Coast States is not discussed in this paper. Only engines using heavy fuels are referred to.

Presented at the Panama-Pacific International Exposition meeting, San Francisco, September 1915, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper may be obtained in pamphlet form; price, 10 cents to members, 20 cents to non-members.

The fuel was sprayed into an external vaporizer (separate from the cylinder), heated by the exhaust gases, the ignition being effected by an electric ignitor.

Fig. 2 is a card from a Hornsby-Akroyd engine, 1890 type, with hot-surface vaporizer constructed without the partial water jacket of later engines, and with very low compression pressure. The engine represented developed 6 h.p. at 216 r.p.m., with fuel having a heating value of 19,000 B.t.u. and specific gravity 0.8410. Fuel consumption 1.0 lb. per b.h.p.-hr. and thermal efficiency 13.5 per cent. The initial pressure was 120 lb. per sq. in., exhaust pressure 20 lb., compression pressure 40 lb. and m.e.p. 35 lb.

In subsequent types of the same engine, the compression pressure was increased with consequent increase in thermal efficiency.

This is shown in Figs. 3 and 4, which are diagrams from 1893 and 1905 types Hornsby-Akroyd engines respectively. Fig. 3 represents an 8.02-in. by 14-in. engine developing 5 h.p. at 214 r.p.m.; initial pressure 120 lb. per sq. in., ex-

FIG. 9 PERIODS OF INJECTION OF FUEL

haust pressure 22 lb., compression pressure 46 lb., m.e.p. 37.5 lb.; heating value of fuel 18,600 B.t.u., specific gravity 0.824, fuel consumption 0.99 lb. per b.h.p.-hr. Thermal efficiency 13.8 per cent.

Fig. 4 is taken from an engine with cylinder diameter 14.5 in. and stroke 17 in.; r.p.m. 202; initial pressure 168 lb. per sq. in., exhaust pressure 30 lb., compression pressure 60 lb., and m.e.p. 48 lb. B.h.p. 27. Heating value of fuel 19,000 B.t.u., specific gravity 0.825. Fuel consumption 0.74 lb. per b.h.p.-hr. Thermal efficiency 18 per cent.

Fig. 5 is taken from a De La Vergne oil engine, type DH, built in 1913. Cylinder diameter 14 in., stroke 24 in. Initial pressure 325 lb. per sq. in., exhaust pressure 25 lb., compression pressure 169 lb. and m.e.p. 75 lb. Heating value of fuel 18,500 B.t.u., and fuel consumption 0.543 lb. per b.h.p.-hr. Brake horsepower 60 at 210 r.p.m. Thermal efficiency 25 per cent.

Fig. 6 is a diagram from a Ruston Proctor engine, type 1913. Initial pressure 550 lb. per sq. in., approximately, exhaust pressure 25 lb., compression pressure 280 lb. and m.e.p. 70 lb. Heating value of fuel 19,000 B.t.u. Fuel consumption 0.46 lb. per b.h.p.-hr. Thermal efficiency 29 per cent.

A diagram from a De La Vergne engine, type FH, 1915, is shown in Fig. 7. Cylinder diameter of this engine 17 in. and stroke 27½ in. Initial pressure 475 lb. per sq. in., exhaust pressure 30 lb., compression pressure 260 lb. and m.e.p. 82 lb. Engine develops 100 h.p. at 200 r.p.m. Fuel

consumption 0.450 lb. per b.h.p.-hr. of California crude oil, having a heating value of 18,500 B.t.u. Thermal efficiency 30.5 per cent.

Fig. 8 is taken from a Diesel engine, type 1915, cylinder diameter 18.875 in. and stroke 28.375 in. Initial pressure 550 lb. sq. in., exhaust pressure 40 lb., compression pressure 550 lb. and m.e.p. 95 lb. Heating value of fuel 19,266 B.t.u., and fuel consumption 0.407 lb. per b.h.p.-hr. Thermal efficiency 32.5 per cent.

It will be noted from these diagrams that the thermal efficiency, 12.8 per cent in 1888, has through improvement

FIG. 10 CROSS-SECTION OF COMBUSTION SPACE OF DE LA VERGNE OIL ENGINE

FIG. 11 SECTION OF RUSTON PROCTOR OIL ENGINE CYLINDER

in design and by increased compression pressures in the later engines been increased to 30.5 per cent in the hot-surface type of oil engine. In the Diesel type it is now 32.5 per cent. All calculations are on the basis of brake or actual horsepower and not indicated horsepower.

TYPES OF ENGINES

Previous to about 1892 all oil engines were of either the hot surface or electric ignition type, with the fuel injected during either the first outward stroke of the piston or air inlet period of the cycle. In Fig. 9 are shown the periods of injection in the different types referred to.

A description of the Diesel system was first published about 1892. In the Diesel cycle the fuel injection period did not take place until compression was completed, or nearly so, and the compression pressure was carried to a point where a temperature sufficient to cause ignition was obtained. High

pressure (about 1000 lb.) air was injected with the fuel, thoroughly atomizing or pulverizing it, and thus sufficient pressure to overcome that existing in the combustion space at the time of injection was obtained. This system gave in 1892 the highest thermal efficiency, as it does today.

Realizing that moderate sized oil engines of from about 75 h.p. to about 400 h.p. and a thermal efficiency somewhat less than that attained in the Diesel type and with lower range of pressures could be produced with some advantages and at less expense, various manufacturers in Europe and in this country have built so-called semi-Diesel or hot-surface type engines, embodying the Diesel method of fuel injection, but in some cases without the air blast.

FIG. 12 SECTION OF WILLANS-ROBINSON CYLINDER HEAD

Regardless of their cycles of operations, at the present time oil engines may be divided into two classes: *Diesel* and *hot-surface type* or *semi-Diesel*. With the exception of the engine shown in Fig. 16, all engines here illustrated are of the 4-cycle type. The majority of manufacturers in Europe and in this country are building 4-cycle types for stationary and marine purposes. With its comparative simplicity, the 2-cycle engine may have decided advantages in the smaller sizes. In the larger sizes the advantage for stationary service is reduced cost of manufacture, while for marine service, reduced weight and space occupied is also claimed by the advocates of the 2-cycle type. From cylinders of the

TABLE 1 OPERATION OF FOUR OIL ENGINES DURING 1904

Engine No.	Desired period of operation, hr.	Actual period of operation, hr.	Per cent of desired period
1	6803.80	6684.54	98.25
2 (spare unit)	700	700	100
3	8536.75	8411.55	98.30
4	8026	8157.47	98.05

same dimensions the power is about 70 per cent greater and the fuel consumption is regarded as approximately 10 per cent greater. Accumulated heat in cylinder head and other parts surrounding the combustion space and main crankshaft bearing troubles have, however, given some European builders considerable difficulty with the 2-cycle type in the larger sizes.

Figs. 19 and 20 show the combustion space, the fuel inlet

and the arrangement of air inlet and exhaust valves of representative Diesel engines.

Fig. 10 is a section of the combustion space of the hot-surface type engine where the fuel and high-pressure air are not injected into the combustion space, as in Figs. 19 and 20, but are first forced into a vaporizing chamber which is heated before starting and in which the temperature is maintained by the combustion of the fuel in it.

The combustion space of another hot-surface type engine in which somewhat of the same system of operation as in the previous engine obtains is illustrated in Fig. 11,¹ but here the air is not injected with the fuel as in the engine in Fig. 10, but a mechanical sprayer or pulverizer is used and a slight amount of water is also allowed to enter the chamber in addition to the fuel.

DESIGN

The general construction of both Diesel and hot-surface types of engines is shown in the different illustrations. Examination of the different details of construction of the very large number of Diesel and other oil engines built in different countries of the world shows many interesting designs.

FIG. 13 ARRANGEMENT OF JUNKERS OIL ENGINE

It would not be feasible here to refer to all the different details of construction. Important elements of large modern oil engines are:

a) Cylinder heads,

b) Trunk piston or crosshead and shorter piston,

c) Sprayer or pulverizer.

Cylinder Head. Considerable difficulty was in the past experienced with the cylinder heads of Diesel as well as of hot-surface type engines due to fracture largely attributable to high temperatures and pressures obtaining in the combustion space. In recent years this difficulty has been largely or entirely overcome. In some cases the reason for this trouble was improper casting, the cores shifting and causing unequal thicknesses of the walls of the cylinder head. Amended and improved design in modern engines has, in most types, eliminated this trouble. The heads are now made of such

¹ Shown by permission of Messrs. Iliffe & Co., London, Eng.

design and material that uniform thickness of the walls is obtained, and the material (soft charcoal iron or its equivalent) is such as to allow easy and uniform expansion and contraction.

Various designs of cylinder heads, among which the following are of interest, have been made to simplify the castings: Fig. 12' shows the cylinder head of the engine made by Willans-Robinson, Rugby, England, and by the Dow Steam Pump Co. in California. This is a notable design and with it the strains due to contraction in the foundry are reduced. In this cylinder head recesses are only made for the insertion of the air inlet and exhaust valves. The fuel inlet valve is inserted in a tube which has different diameters at its ends and which is pressed into place between the lower and upper facings of the walls of the cylinder head. The starting

cylinder, that farther from the crankshaft moving in the opposite direction to that nearer the crankshaft and both being connected by suitable crosshead and connecting rods to the outside cranks at 180 deg. from the main crank. In this type, the fuel is injected into the combustion space formed between the two pistons.

Piston and Crosshead. The trunk piston without crosshead is shown in Figs. 19 and 20. In 4-cycle, single-acting engines developing over 150 h.p. in one cylinder a cross-

FIG. 14 SECTION OF M. A. N. PISTON

FIG. 15 SECTION OF SABATHE SPRAYER

air valve is similarly inserted in a separate tube. No recess is cored in the cylinder head for these valves and in this way the shape of the castings is simplified and unequal masses of metal are eliminated.

A part section of the Junkers type of Diesel engine in which the cylinder head is eliminated entirely is shown in Fig. 13. This engine is equipped with two pistons in each

head is recommended. The advantages of the crosshead type may thus be stated:

- (1) The guides in which the crosshead moves are maintained at an even temperature and are not subject to the expansion and contraction of the cylinder that they are with the trunk piston.
- (2) It is simpler to lubricate the crosshead pin than the trunk piston pin, as the former does not come in contact with the heated parts of the engine.

* Figs. 12, 13, 19 and 20 are reproduced by special permission of Messrs. Spon and Chamberlain, publishers of "Marine and Stationary Diesel Engines," by the author (in press).

TABLE 2 POWER GENERATION COSTS FOR 1914

Estimated output		Oil consumed				Cost of operation, dollars								Total cost dollars
At switchboard kw-hr.	At engines h.p-hr.	Gal.	Lb.	Lb. per		Labor		Materials and supplies						
				Kw-hr. switch- board	H p-hr. engines	Operat- ing	Main- tenance	Fuel oil 16 2/3 gal.	Lubricating oil 7 1/2c. per 1000 h.p-hr.	Repair parts	Belts	Misc. supplies		
2,469,293	3,996,196	278,595	2,061,692	0.81	0.52	7907.31	2241.76	46603.62	2838.82	1659.50	792.92	1041.64	63058.57	
Per kw-hr.		0.113	0.835			0.0032	0.0009	0.0188	0.0011	0.0007	0.0008		0.0255	
Per h.p-hr.		0.083	0.516			0.0020	0.0006	0.0116	0.0007	0.0004	0.0005		0.0158	
								Fuel oil 2 1/7c. gal.	Lubricating oil 35c. per 1000 h.p-hr.					
								5969.29	1400.00				20985.42	
Per kw-hr.								0.0024	0.00057				0.0086	
Per h.p-hr.								0.0015	0.00035				0.0053	

Based on \$640 hr. per year, that is with fuel at 16.5c. per gallon and lubricating oil 7 1/2c. per 1000 h.p-hr. equivalent to: \$136.54 per h.p. year at the engines
\$ 164.41 per kw. year at the switchboard

Or with fuel oil at 2 1/7c. per gallon and lubricant at 35c. per 1000 h.p. hours equivalent to: \$15.70 per h.p. year at the engines
74.50 per kw. year at the switchboard

The last named figures are given showing costs under ordinary conditions. Allowance must be made for increased cost of materials and supplies due to excessive charge for transportation.

- (3) The guides of the crosshead type can be more easily adjusted, whereas the ordinary trunk piston does not allow of adjustment.

Advocates of the trunk piston in preference to the crosshead type point out that the wear in the cylinder is due to the piston rings and not to the friction of the trunk piston, that in a well designed engine the pressure of the piston on the

Sprayer or Pulverizer. A most important feature of all oil engines is the sprayer or pulverizer through which the fuel and high-pressure air are injected into the combustion space. Its function is to thoroughly atomize the fuel and mix the particles with the air before the latter enters or as it enters the combustion space.

Where a heavy crude oil or tar is the fuel, a slight amount

FIG. 16 250-H.P. 2-CYCLE SNOW OIL ENGINE

FIG. 17 60-H.P. 4-CYCLE SNOW OIL ENGINE

cylinder walls is so slight, its proper lubrication can easily be maintained and that the crosshead type requires more space and is more expensive to manufacture.

Fig. 14 shows the type of piston made by the M. A. N. in Germany. This is equipped with loose strips on its upper surface which permit adjustment to take up the wear on the piston. The makers of this type claim for it the advantages of a crosshead without the disadvantages of greater cost of manufacture and the occupation of more space.

of lighter fuel is used in addition. The sprayer is then equipped with two openings and passages properly arranged so that the lighter fuel enters the combustion space and ignites before the heavier fuel enters. The temperature is raised and the ignition of the heavier fuel is facilitated. Separate fuel pumps are used for each fuel.

An interesting fuel inlet valve is that used by the Société des Moteurs Sabathé with their engine for submarine use; this valve is shown in section in Fig. 15. It is equipped with

FIG. 18. DE LA VERGNE OIL ENGINE AT OAKLAND, CAL.

two valves, one of which is the ordinary type of fuel inlet valve and the second is larger in diameter and loose on the former, being held in place by the spring as shown. This fuel inlet arrangement is designed to effect "mixed combustion" by allowing two periods of fuel injection. Its principle is as follows: The fuel injection from the first valve is arranged to enter the combustion space when the compression is about 450 lb. and the volume is constant, with the result that the pressure instantly rises. Immediately afterwards the injection of fuel from the upper passage hitherto held in check

ated in different installations, some for three months, some for six and others for eight months continuously, day and night without stoppage, and with different crude oils.

Current of Europe, East Asia and return.

Extract from paper read by Mr. L. Kaudsen, Malmo, Sweden, July, 1914.

by the larger valve is allowed to slowly enter the combustion space while the volume is increasing. The movement of the valves is, of course, mechanically controlled and the timing of injection can be altered to suit the requirements of varying speeds. Economy of injection air as well as greater efficiency is claimed for this type.

RELIABILITY AND ECONOMY

One of the most important questions of the operation of oil engines and one frequently discussed and referred to by those who are not fully informed on the subject, or who are seeking information, is in regard to reliability of operation. The most forcible reply is that many oil engines have oper-

FIG. 20 SECTION OF BURMEISTER AND WAIN OIL ENGINE

Arizona which is operating continuously 24 hr. per day. This plant is equipped with four hot-surface type engines, two of 180 b.h.p., one 250 b.h.p. and one 280 b.h.p., belted to shafting or direct connected to electric generators. The engines are installed at an altitude of about 7000 ft.; they are 90 miles from a railroad station and oil fuel and supplies have to be hauled this distance over mountain roads. The cost of hauling is approximately one cent a pound, which accounts for the high cost of fuel, viz: 16.5 cents per gallon. The engines operate on fuel oil of 22-deg. Beaumé. Table 2 shows power generation costs of the same installation for the year 1914.

The advantage of the oil engine for operating almost any class of machinery in comparison with other prime movers is conceded, but for its economy to be fully realized the load factor should be as high as possible.

EXAMPLES OF ENGINES

Fig. 16 shows a 250-h.p. twin-cylinder 2-cycle Snow Diesel horizontal oil engine, direct connected by flexible coupling to a 60-cycle alternator and operating with California and Mexican crude oils; this engine has been in operation about six months. Fig. 17 shows a 60-h.p. single cylinder 4-cycle horizontal Diesel engine by the same maker, operating with 18-deg. Beaumé California crude oil and driving by belt a deep well pump. This plant has been running about four months.

In Fig. 18 is shown a 280-h.p. type FII De La Vergne oil engine operating an ice machine and electric generator by belt and using California crude oil, 14-deg. Beaumé. This installation is at Oakland, Cal., and has been in operation for about one year. The manufacturers of this engine guarantee it to operate on any fuel or crude oil produced in the United States and Mexico having 18,000 B.t.u. and not more than 1 per cent water. This engine has operated for 800 hr. continuously without stopping. Between Nov. 23, 1914, and July 23, 1915, the plant was in operation 5400 hr. during which period 12,330 tons of ice were manufactured.

Fig. 19 shows a partial sectional view of the McIntosh-Seymour enclosed type vertical 4-cycle 4-cylinder single acting stationary Diesel engine of 500 h.p., with 2-stage air compressor for furnishing high pressure injection air placed in line with the motor cylinders and operated, as is now standard practice, from an overhung crank on the main crankshaft.

This drawing shows one of the most recently developed Diesel vertical engines in this country. The details of design, such as cooling, pulverizing of the fuel, valve motion, etc., have had careful attention. While the illustration shows the enclosed crank case type of engine, the latter is also made with "A" frame construction.

The Burmeister and Wain Diesel marine 4-cycle single acting type engine built by this firm in Copenhagen, Den-

mark, and installed in the latest motor ships made by them is shown in Fig. 20. Each engine has six cylinders, 29 9/64-in. diameter and 43 5/16-in. stroke, and develops 2000 i.h.p. at 100 r.p.m. The engines are reversible by longitudinal movement of the camshaft in the regular way.

There are many interesting features in this engine, notably the spray valve which has two coned surfaces, one forming the valve seat and the other spreading the spray. It opens outward towards the piston, instead of inwards as in most types; in this way the spray of fuel is very evenly distributed throughout the whole of the combustion space and the heat evolved during combustion is distributed over the whole area of the piston. The process of starting and maneuvering is simplified by the starting valve which is automatically operated by the pressure of the air and only requires the opening of one valve. In this type of engine the camshaft is operated from the crankshaft by a chain of spur gears,

FIG. 21 SECTION OF DE LA VERGNE OIL ENGINE

which system has replaced the vertical intermediate shaft and gearing previously used.

This design is considered one of the most successful marine engines in large sizes and several motor ships equipped with it have made long voyages. In a paper by I. Knudsen, read in July, 1914, at Malmo, Sweden, the figures in Table 3 showing particulars of a long voyage of one of these motor ships in comparison with a steamship of the same dimensions were given.

Yearly fixed charge is arrived at as follows: interest, 6 per cent; taxes and insurance, 1 per cent; repairs, 3 per cent; depreciation, 10 per cent.

Engine using distillate 48-54 deg. B. oil has a thermal efficiency of 20 per cent under full load.
Engine using tops distillate 38-42 deg. B. oil has a thermal efficiency of 20 per cent under full load.
Semi-Diesel engine using 24-28 deg. B. oil has a thermal efficiency of 18 per cent under full load.
Hot surface-high economy engine using 16 deg. B. oil has a thermal efficiency of 27 per cent under full load.
Diesel engine using 18 deg. B. oil has a thermal efficiency of 28 4 per cent under full load.

OIL ENGINES IN PIPE LINE SERVICE

CALIFORNIA FUELS

Fig. 21 shows a sectional view of the latest design of De La Vergue 150-h.p. single and 300-h.p. twin-cylinder oil engine. In this construction the valve motion consists of the camshaft geared to the crankshaft in the ordinary way, but this intermediate shaft actuates a second shaft placed behind the cylinder head and operating parallel to the crankshaft. The air and the exhaust valves are so arranged that they can be easily removed and the piston is made of greater length so as to reduce the pressure and minimize the amount of wear between it and the cylinder walls. Details of lubrication of all bearings and other moving parts have been improved. The piston pin is lubricated through the hollow connecting rod.

In 1902, the writer arranged and introduced the oil engine for oil pipe line pumping service. A number of engines for this service were first installed for the Gulf Pipe Line Company in Texas and since then the installation of several hundred engines with many of the leading pipe line companies in the south or southwest territories has followed. These pumping stations consist of several units, some stations

The oil engine for pipe line service has not yet been used to any extent in the California oil fields. Table 4¹ shows the characteristics of California crude oils, while Fig. 22 gives results of distillation tests. It is necessary to heat such a temperature that they will flow readily in the pipe lines and can be satisfactorily handled by the pump. The amount of heat necessary to raise the temperature of crude oil of 15-deg. Beaumé, assuming its specific heat to be 0.333 (which value seems to be difficult to exactly determine), is shown by the following remarks:

The amount of oil pumped per b.h.p.-hr. at a pressure of 570 lb. is 135 gal. and the heat required to raise this quantity of oil through a range of 41 deg., or from a temperature of 69 deg. to 110 deg. Fahr., would be 18,400 B.t.u. The amount of waste heat from an oil engine consuming half a pound of fuel per actual h.p.-hr., both from the waste heat of the water jacket and that recoverable from the exhaust, with the most advantageous arrangement, is approximately 4200 B.t.u. Thus, taking this waste heat, it is evident that 14,200 B.t.u. per b.h.p. of the pumping outfit per hour would have to be furnished from an outside source to provide sufficient heat to raise the oil to the required temperature.

In a steam pumping plant this can be advantageously taken from the exhaust steam of the steam plant. The fuel consumption of the average steam pumping plant may be taken as 1.5 lb. of oil fuel per b.h.p.-hr., but sufficient heat is in this case also available for heating the crude oil to the temperature above referred to.

With the oil engine plant, 0.5 lb. of fuel per b.h.p.-hr. is required for the actual pumping process and from the figures above it will be seen that an amount of heating equivalent to that developed from a pound of oil would be necessary to heat the oil passing through the pipe line. Thus the total fuel consumption of the oil engine and that of the steam pump, allowing for heating, is approximately the same.

The oil engine outfit can operate with a poor quality of cooling water which would, however, be unsatisfactory for boiler use. This is a great advantage in favor of the former in many localities where only a poor quality of water can be procured.

Table 5² shows the costs of installation and operation of the different types of engines specified prevailing in California in 1914. The prices quoted for each fuel may not now be correct and the costs of fuel may require slight modification to conform with prevailing prices. The writer is informed that the price for 48 to 50-deg. Beaumé distillate is 6 cents per gal. in 110-gal. drums, while Diesel fuel oil is quoted at 85 cents per 42-gal. barrel in tank cars 25 miles north of San Francisco. Calol fuel oil 24-deg. Beaumé is 75 cents per 42 gal. and fuel oil not less than 14-deg. Beaumé is 60 cents per barrel in tank cars f.o.b. Richmond, Cal. The yearly fixed charge of 20 per cent is a higher rate than is usual to allow in the Eastern States where 5 per cent interest and 5 per cent depreciation are considered sufficient.

FIG. 22 CURVES SHOWING DISTILLATION TESTS OF FUELS

having as many as six engines. The capacity of each unit varies from 90 to 150 h.p. and is composed of the engine direct connected to a vertical or horizontal power pump. The former installations were equipped with friction clutch couplings between the engines and the pumps. In the later installations the connection used between engines and pumps is a flexible coupling or, in some cases, a rigid coupling. The pump is furnished with a by-pass between the suction and discharge so that, in starting the engine, the load is very much reduced. In the latest arrangement of this pumping unit the oil engine flywheel is placed close to the out-board bearing. In this way the main bearings are relieved of this weight and unequal wear on the bearings is avoided.

This type of pumping outfit was fully described in a paper³ before the Society by Forrest M. Towl, where it was stated the total efficiency of an 85-h.p. engine in three tests was 26.8, 27.75 and 27.52 per cent, respectively. The efficiency of pump and transmission was stated as 92.1 per cent. The fuel consumption per pump horsepower by displacement was 0.5171 lb. Tests were made with 33-deg. Beaumé fuel having a heat value of 19,059 B.t.u. per pound.

THE STRENGTH OF GEAR TEETH

BY GUIDO H. MARX AND LAWRENCE E. CUTTER,

PALO ALTO, CAL.

Members of the Society

(SECOND PAPER)

THE investigations reported upon in this paper were undertaken for the purpose of supplementing those presented to the Society at its Annual Meeting of 1912, by the senior author.¹ The methods of conducting the tests, and of mathematical analysis employed in working up the results, were substantially the same as described in the earlier paper and are not repeated here. Paragraph references to the first paper will be used to direct attention to explanatory matter which is here omitted.

The limitations of the apparatus available for the earlier experiments made it impossible to secure positive data at pitch speeds exceeding 500 ft. per min., although significant data of a negative character were obtained at speeds up to 1000 ft. per min.²

In order to get positive data at high pitch speeds, an improved form of the apparatus used in the earlier experiments was devised³ and connected by chain drive to a 50-h.p. motor capable of taking care of momentary overloads of 100 per cent. The main difference between the new apparatus and the old lay in the employment of Hess-Bright ball-bearings throughout in place of ordinary journal bearings. Each shaft was carried on two of these radial bearings, No. 307.

A second improvement was in the prony brake (Fig. 1).

This was devised to be self-contained, the friction load due to scooping up the circulating cooling water being weighed on the scales with the rest of the friction load. It worked with great steadiness and proved eminently satisfactory. Owing to the high rim speeds reached, the brake wheel was carefully finished all over and had a web in place of arms.

FIG. 1 PRONY BRAKE

A few holes drilled through the web at its outer circumference permitted the free circulation of the cooling water.

OUTLINE OF TESTS

The gears which were tested were made by The Brown & Sharpe Mfg. Co. and the Fellows Gear Shaper Co. The in-

ABSTRACT OF PREVIOUS PAPER ON THE STRENGTH OF GEAR TEETH, By GUIDO H. MARX

The teeth of gear wheels when transmitting power are individually subjected to an action akin to that applied to a beam fixed at one end, with a load somewhere between the fixed and the free ends. All standard formulae or diagrams for the proportioning of such teeth therefore involve a factor representing the allowable unit fiber stress in a cantilever beam subjected to a bending moment.

The experiments described in this paper were undertaken with the primary purpose of throwing some light upon the question of this allowable unit fiber stress for modern cut cast-iron gear teeth under operating conditions, since definite data upon this point have been lacking, particularly with reference to the effect of pitch line velocity.

The formula for the safe equivalent load at pitch line as derived from these experiments is:

$$W = \frac{spf}{k} \left(0.154 - \frac{1.26}{n} \right) cu$$

in which

W = safe working load at pitch line in lb.

s = modulus of rupture = 39,000 in these tests, but ordinarily to be taken = 36,000

p = circular pitch in in.

f = width of face in.

k = factor of safety

n = number of teeth in gear

v = velocity coefficient from table below

a = arc of action coefficient from table below

COEFFICIENTS BASED ON ARC OF ACTION

vestigation divided itself into the following main divisions:

- a Tests on 30T meshing with 40T, Brown & Sharpe $14\frac{1}{2}$ -deg. involute, at pitch speeds from 500 to 2000 ft. per min. to determine velocity coefficients, v , to supplement those derived in the earlier experiments for speeds below 500 ft. per min.¹
- b Tests on 30T meshing with solid 60, 80, 100, and 150T Brown & Sharpe $14\frac{1}{2}$ -deg. involute, to supplement ear-

FIG. 2 RELATION BETWEEN PITCH SPEED AND BREAKING STRENGTH OF BROWN & SHARPE 30- AND 40-TOOTH $14\frac{1}{2}$ -DEG. INVOLUTE GEARS

FIG. 3 RELATION BETWEEN PITCH SPEED AND BREAKING STRENGTH OF FELLOWS 30- AND 40-TOOTH 20-DEG. INVOLUTE STUB-TOOTH GEARS

lier tests on effect of arc of action, to determine more fully arc of action influence.

- c Tests on 30T meshing with 40T, Fellows 20-deg. involute stub-tooth, for speeds from zero to 2000 ft. per min. to determine velocity coefficients, v , for this form of tooth.
- d Tests on 30T meshing with 20, 40, 60, 80, and 100T, Fellows 20-deg. involute solid gears, on effect of arc of action, to determine arc of action coefficients, a , for this type of gear.
- e Static tests on Fellows gears to determine actual breaking strength of individual teeth, for determination of

experimental values of factors for form of tooth as determined by the number of teeth in gear (Lewis's factor y). See Par. 28, paper 1382.

The Brown & Sharpe gears were of their standard 10 diametral pitch, $14\frac{1}{2}$ -deg. involute form and those used in the tests involving the effect of pitch speed (Tests 1-12 inclusive) were sent from stock. These stock gears having a width of face of $1\frac{3}{16}$ in. were reduced by us to the width of $1\frac{1}{16}$ in. for which the apparatus had been constructed. The 30 and 60T gears were solid discs and the others were webbed, in order to eliminate the effect of weakness of arms and rims; the 80, 100 and 150T gears were made from patterns furnished by the authors. Solid grease lubricant liberally applied was used on all gears.

The Fellows gears were all of their $10\frac{1}{12}$ -pitch, 20-deg. involute form, and were solid discs in every case.

All gears when tested had the width of face of $1\frac{1}{16}$ in. The 20 and 30T gears (except the 30T gears of Tests 24A

FIG. 4 RELATION OF BREAKING LOAD TO ARC OF ACTION; FELLOWS 20-DEG. INVOLUTE AT 500 FT. PER MIN. PITCH SPEED

and 25A) had a bore of $1\frac{1}{16}$ in., and all others had a bore of $1\frac{1}{8}$ in.

The material (cast-iron) was tested in all cases by means of specimens cut from the gears themselves¹ and the results are given in detail in an appendix. The gears of each manufacture were furnished in two separate installments. The material of the gears furnished for the tests on influence of arc of action (Tests 13-20 and 18A-23A inclusive) was stronger in both cases than that of the gears previously furnished for the tests on influence of pitch speed (Tests 1-12 and 1A-17A inclusive). Where the variation of the strength of material was such as to call for a correction in order to get consistent and comparable results, this was made; but in all cases the actual test results are given first.

SERIES A: TESTS TO DETERMINE VELOCITY COEFFICIENTS, BROWN & SHARPE GEARS

Table 3 of velocity coefficients, v , (Par. 21, paper 1382), for Brown & Sharpe $14\frac{1}{2}$ -deg. cast-iron gears may be considered as quite definitely established for the entire range of speeds from zero to 2000 ft. per min. An explanation follows of the method by which these values were derived, from which it would appear to be safe to extrapolate beyond

¹ Par. 2, 7 and 21, paper 1382.

² Par. 22, paper 1382.

the speed of 2000 ft. per min., if desired,—safer than to make the tests. In fact, the authors are entirely willing to leave the conduct of all tests at higher pitch speeds to those who would like to see them made.

The data from which the values in Table 3 were derived are given in Tables 1 and 2 and in Fig. 2. Table 1 gives the results of the supplementary tests on the effect of speed on breaking strength of Brown & Sharpe 14½-deg. involute, 1/16-in. face, 30T meshing with 40T. The experiments previously reported¹ for gears of these sizes and this type gave results up to a pitch speed of 415 ft. per min. These results, together with those of Table I, are plotted in Fig. 2, Curve A.

In Par. 14 to 17 of Paper 1382, attention was called to an apparent rise of strength at speeds above 300 ft. per min. and the tentative suggestion advanced that this might be due to passing a maximum percussive effect. The tests at the speeds above 500 ft. per min. failed to maintain this view. Moreover, the tests on the Fellows gears reported on in a later section of this paper showed no such phenomenon. In the latter case ball bearings were used throughout for the series of tests involving 30T and 40T gears. The explanation of the irregularity of the Brown & Sharpe curve (including the phenomenon of its rise) lies in the use of ordinary journal bearings in the first set of experiments. The friction of the brake shaft bearings was neglected. In the original paper it was assumed that the only effect of this is to make the computed breaking load of the teeth a very little less than its real value in each case.

A study of journal friction and variations of coefficients of friction with speed, made by the senior author in another connection, clears up this matter. Without entering into detail, the coefficient of friction of the journals used in the earlier apparatus is a variable, being greatest at zero velocity and decreasing to a minimum at about the rotative speed corresponding to the pitch speed of 415 ft. per min. At this speed the coefficient of friction (perfect film lubrication) is not widely different from the practically uniform coefficient of friction for ball bearings. Had this variable effect of friction not been neglected, the actual curves would probably not have shown this fall and subsequent rise.

If due allowance be made for this frictional resistance and it be properly added to the observed breaking load in each case, the actual curve for the entire range would be approximately that shown by the dotted line up to the speed of 500 ft. per min., and the full line from there on to 2000 ft. per min. (Curve A, Fig. 2). A correction was made for the added

load on the gear due to journal friction for the test at zero velocity, assuming a value of 0.20 for the static coefficient of friction, giving as a result an added load of 175 lb. on the tooth, thus bringing the average value up to 2435 lb. for zero velocity. It is on the side of safety to base the coefficient of velocity, v , on this value.

The stock gears used in Tests 1 to 12 showed a wide variation in material as indicated by flexure tests. Since the material of the similar gears reported upon in Paper 1382 had a very uniform modulus of rupture of about 39,000 lb. per sq. in., it would seem better to reduce the actual results of the present experiments to a basis of a uniform modulus of rupture of 39,000 if the two sets of observations are to be combined. This has been done in the last column of Table 2. Fig. 2, Curve B, shows the results graphically. An explanation of this variation of strength probably lies in the reduction of the width of face of these gears after their receipt by us. The removal of one-eighth of an inch at one surface or the other would have a marked effect, since the surface material is recognized as being the stronger. If this material were removed on the side which originally had had the greater depth of cut taken from it in finishing the gear blank, the result would be different from that if the reduction in width had been made on the other surface.

Objection may be made to using Curve B rather than Curve A for the determination of the velocity coefficients. It is to be noted, however, that this reduction, made for the purpose of having the present and earlier experiments more justly comparable, also makes the present test results more consistent and it gives velocity coefficients which, being lower than those which would be derived from Curve A, are on the side of additional safety.

SERIES B: TESTS TO DETERMINE INFLUENCE OF ARC OF ACTION, BROWN & SHARPE GEARS

The experiments under this head were originally planned (when the gears for the series were ordered) to supplement those on the influence of arc of action, described in Par. 32, paper 1382, and shown there in Fig. 9, Curve B; but subsequently it was decided to run the tests independently of the previous ones, at a pitch speed of approximately 500 ft. per min., in order to make them comparable with the Fellows tests, Nos. 5A, 6A, 18A, to 23A inclusive, described later in the present paper, which had already been made at this speed. Table 4 gives the results.

The unusually high modulus of rupture shown by the material of most of the gears used in this set of tests, made it seem desirable to adopt the expedient of reducing the actual

test results to a basis of an imaginary uniform material having a modulus of rupture of 39,000 lb. per sq. in.

It is impossible, however, to get any satisfactory light out of this series of tests on the actual influence of the arc of action. While the unmodified results, with the exception of Tests 13 and 14, are not incompatible with those obtained in the earlier paper, when reduced to a basis of a uniform modulus of rupture they show an apparent falling off of breaking strength with increase of arc of action for ratios of arc of action to pitch are greater than 2. This may actually be the case, but it is contrary to the effect of ratio of arc of action to pitch are for values ranging from 1 to 2 and does not seem rational. It is also contrary to the results given in Tables 10-14, paper 1382.

It must be borne in mind that reducing the tests to a uniform modulus of rupture on the basis of a test bar cut from the gear is only a crude expedient adopted in default of a better. Cast iron is too variable a material to permit certainty that the strength at the tooth which first yielded was just that of the test bar. In addition, we have the fact that the teeth do not fail by pure flexure and that, therefore, using the modulus of rupture for flexure as the unifying basis is open to some question. But it is equally evident that material which showed as much variation as did this calls for the reduction of test results to some kind of comparable basis.

Thinking that the discrepancy of the results might be due to the possible failure of the teeth of the larger gear rather than the smaller, owing to the chance of weaker material in the larger gears, test bars were cut from the 60T and 80T gears of Tests 13 and 15. While the material proved to be a little weaker than that of the corresponding 30T pinions, computations showed that this was more than compensated for by the stronger form of the teeth of the larger gears. This possible explanation of the discrepant results also had to be abandoned.

Another explanation of the reduced results running in the wrong direction may lie in the possibility that the shafts were not exactly parallel. This would cause severer stress conditions the larger the radius of the gear.

Weighing all the evidence, we consider that the arc of action coefficients, a , derived in the earlier paper from experiments on more uniform and normal material, are essentially correct and they are repeated here in Table 5, being extended to a ratio of

$$\frac{\text{arc of action}}{\text{pitch arc}} = 2.2$$

From the way an additional tooth comes into action, as shown by the imperceptible increase

of a for the range from a ratio of 1 to a ratio of 1.4, it is probable that the value of a remains at about 1.6 from a ratio of 2 to a ratio of 2.4.

The gears employed in Tests 13 to 20 inclusive were made from special patterns sent to the manufacturers. All of them were solid or webbed and the hubs were lengthened to permit a $2\frac{1}{2}$ -in. key being used; this precaution being necessary because of the longer lever arm of the tooth load.

It was intended to carry out tests on the static strength of the individual teeth of these gears, as shown in position A, Table 8, paper 1382, but because of the exceptional strength of the material, which caused the shaft to spring, it was not certain that the teeth were being held in the proper relation at the instant of rupture and this purpose was abandoned. The experimental value of the factor for form of tooth (Lewis's factor y), as determined in Par. 29 and Appendix 4, paper 1382, is therefore retained, being—for the Brown & Sharpe $14\frac{1}{2}$ -deg. involute teeth—equal to

$$\left(0.154 - \frac{1.26}{n}\right)$$

where n is the number of teeth in the gear.

SERIES C: TESTS TO DETERMINE VELOCITY COEFFICIENTS, FELLOWS GEARS

The tests for effect of pitch velocity on the breaking strength of Fellows 20-deg. involute, stub-tooth gears, $\frac{19}{32}$ -pitch, $1\frac{1}{4}$ -in. face, 30T meshing with 40T, gave remarkably uniform and consistent results. These are tabulated in Table 6 and shown graphically in Fig. 3. This uniformity is in a large measure due to the uniformity of the material of this set of gears, but may also have been influenced by the method of cutting. We had no apparatus to measure accuracy of tooth spacing and made no attempt to do so.

From the curve of Fig. 3, Table 7 of velocity coefficients, v , for Fellows 20-deg. involute gears has been computed. It will be noted that these values of v correspond quite closely to those obtained in the experiments with the Brown & Sharpe gears. (Compare Table 3.)

In the case of the Fellows tests the expedient of plotting the breaking loads reduced to a uniform modulus of rupture, and basing the velocity coefficients upon this curve, was not resorted to, as it was in the case of the Brown & Sharpe tests. The material of the gears used in this set of tests, 1A to 17A inclusive, being from a single melt, showed only moderate variation in the flexure tests and had an average modulus of rupture of 39,600 lb. per sq. in. For this reason, and for the further reason that the velocity coefficients derived from the reduced curve would be slightly higher than those derived from the actual test results and therefore

tend away from safety rather than toward it, no curve is drawn in Fig. 3 reducing the actual test results to a uniform basis of a modulus of rupture of 39,000 lb. per sq. in. Table 8, however, gives the results of reduction computations in the same manner as shown in Table 2 for the Brown & Sharpe gears and is included here to complete the record. If the modified results be plotted it will be noted that they are not as regular and consistent as the actual test results.

SERIES D: TESTS TO DETERMINE ARC OF ACTION COEFFICIENTS,
FELLOWS GEARS

The shortened addendum used in the Fellows system makes for shorter and less varied arcs of action. By the method described fully in Appendix 3 of paper 1382, the values of the arcs of action for various combinations of Fellows gears were computed. The results are given in Table 9.

Tables 10 and 11 give the results of those experiments

An interesting check is to compare with the results of Table 10, the increase for strength at this speed of 500 ft. per min., for an increase of arc of action from 0.31416 to 0.45008. The ratio of increase of strength is $\frac{1050}{1750} = 1.24$, as before.

Objection may be made to there being too few points to locate the curve of Fig. 4 with reasonable accuracy. As seen in the next paragraph the matter is not vital. The variation in value of the arc of action coefficient, a , in all cases except those involving very small pinions, is so slight that no appreciable error is introduced if it be taken as uniformly equal to 1.25 in the case of the Fellows gears.

Table 12 gives values for the arc of action coefficient,² a , as deduced from Fig. 4 for the gear combinations of Table 9 as covering the ordinary range. The values for others can be computed readily or interpolated with sufficient accuracy. It can be seen that $a = 1.33$ is about the maximum value in

TABLE 14. SUMMARY OF INVESTIGATION OF BREAKING STRENGTH OF BROWN & SHARPE 14½-DEG. INVOLUTE, AND FELLOWS 20-DEG. INVOLUTE, STUB-TOOTH, CAST-IRON, CUT GEARS

SYMBOLS, BOTH SYSTEMS		FORMULAE	
W =safe equivalent load at pitch line, pounds		Brown & Sharpe 14½-deg. involute:

which were made to determine the effect of arc of action on breaking strength in the case of the Fellows gears. From Table 10 it is seen that in the static tests there is an increase in strength in the ratio of $\frac{316}{208} = 1.24$ for an increase in arcs of action in the ratio of

$$\frac{0.45008}{0.31416} = 1.4327$$

Taking account of the single tooth, weakest position, static strength of the 30T gear 2596 lb. as shown by the average of Tests 1B and 2B, and multiplying by the velocity coefficient 0.635 for 500 ft. per min., we get 1591 lb. as the breaking strength at this speed for a 30T Fellows gear with an arc of action of 0.31416.¹ This point is plotted in Fig. 4 with the averages of Table 11, which therefore shows the relations between equivalent breaking load and arc of action for the Fellows gears at this speed.

any practical case as compared with a corresponding maximum of about 1.60 for the Brown & Sharpe system.

SERIES E: DETERMINATION OF VALUE OF FACTOR Y, LEWIS
FORMULA

The next step in the investigation of the Fellows gears was the determination of the expression for the factor depending upon the change of tooth-form as dictated by the number of teeth in the gear. This is Mr. Lewis's well-known factor y . For a 20-deg. involute tooth with addendum equal to $0.8 \div$ diametral pitch, Mr. Flanders³ gives values from which we obtain

$$y = \left(0.173 - \frac{0.720}{n} \right)$$

By laying out the form of the 12, 30, 40 and rack teeth of

¹ Par. 32, paper 1382.

² Par. 33, paper 1382.

³ Trans. A. S. M. E., vol. 30, p. 950.

the actual Fellows $\frac{16}{12}$ -pitch, ten times full size, and employing the method described in Appendix 2, paper 1382, we obtained

$$y = \left(0.169 - \frac{0.972}{n} \right)$$

As was found in regard to the similar factor for the Brown & Sharpe system¹ this method, based upon an unmodified flexure theory, does not correspond to actual conditions. The teeth in every case show much greater breaking strength than either of these values of y would give when substituted in the single tooth static strength formula, $W = spfy$.

A series of tests was made on the static strength of single teeth under conditions of load application corresponding to engagement at their weakest position. This is Position *A*

FIG. 5 MANNER OF TOOTH FAILURE

of Table 8, paper 1382, and corresponds to the maximum strength of such gears when the arc of action is just equal to or is less than the pitch arc (i.e., circular pitch). In this case both velocity coefficient and arc of action coefficient become equal to unity and the value of y can be computed directly. The loads were applied by means of a steel pinion. Par. 27, paper 1382. The results of these tests are given in Table 13. In computing the values of y , s is taken equal to the average shown by all the Fellows test specimens, 40.910 lb., $p = 0.31416$ in.; and $f = 1.9625$ in.

By the method of Appendix 4, paper 1382, these results give approximately a value of

$$y = \left(0.317 - \frac{3.81}{n} \right)$$

But an examination of this equation shows that it would lead to a zero value of y , and hence of W , for $n = 12$, which is obviously incorrect. It would also lead to a value of $W = 4329$ for a rack tooth ($n = \infty$); while the experiments showed that the teeth would fail by shear, as indicated in Fig. 5, rather than by flexure, long before such a load could be reached. A note made in the log at the time of these tests says: "It seems a fair conclusion that these stub-teeth when loaded at the end are apt to fail by shear before reaching a load that would break them out, in the case of 60T gears and larger." Our judgment based upon observed experiments was that this limiting value for a rack tooth end

load would be 3800 lb. Upon this basis and by combination with W for $n = 20, 30$ and 40 ,

$$y = \left(0.278 - \frac{2.69}{n} \right)$$

was deduced. The results derived from its use checked very closely with the actual running test results. Where they depart from the test results in the static cases they do so on the safe side.

It is to be borne in mind that we questioned the test results in these static tests above 40T gears, as we noted in the log that because of the torsional deflection of the shafts we could not be certain that the teeth were in position *A* at the instant of rupture. Any deflection would put them in a position to carry a heavier load.

In the Fellows system of tooth forms the ratio of addendum to pitch is not a constant one for different pitches, hence the results obtained on $\frac{16}{12}$ -pitch gears do not hold with exactness for other pitches. However, the differences in tooth proportions are not sufficiently great to forbid the use of these results with a reasonably close degree of accuracy for other pitches.

CONCLUSIONS FROM ENTIRE SERIES OF TESTS

For convenient reference the conclusions arrived at from the entire experimentation, reported upon in both this paper and No. 1382, are summarized in Table 14. The formulae and factors represent the best judgment of the present writers, based upon painstaking and unprejudiced study of the complete data. The original goal of the investigation, namely the definite determination of the effect of pitch-speed

TABLE 15 CHECK OF FELLOWS FORMULA

Test number	W , by test	W , by formula $s = 39.588$
1A	2575	2622
2A	2711	2629

12A	1562	1480
13A	2953	3081
14A	3256	3081
15A	Void
16A	1403	1399
17A	1380	1393

upon breaking strength, has been attained, we feel, for the ordinary working range of velocities.

Too much stress must not be laid upon the comparison, in individual cases, of the formula results and the test results reduced to the modulus of 36,000. In the non-homogeneous material, like cast-iron, the chances are altogether against the strength of the single test-specimen being exactly that of the tooth which first broke in the gear test. This is borne out by the fact that the actual test value of W sometimes comes out larger in the case of duplicate experiments (all

¹ Par. 29, paper 1382.

conditions the same) for the gear whose material subsequently showed the lower modulus of rupture in the flexure tests. (Examples: Tests 1A and 2A, 3A and 4A.) Again, in many duplicate tests where the differences in breaking strength lay in the same direction as the differences in test-specimen moduli, the tooth strength variation was not as great as the variation in modulus. Examples:

Tests 1 and 2; Ratio of Moduli, 1.135; Ratio of W , 1.075

Tests 4 and 3; Ratio of Moduli, 1.179; Ratio of W , 1.105

Tests 6 and 8; Ratio of Moduli, 1.157; Ratio of W , 1.022

Tests 9 and 10; Ratio of Moduli, 1.131; Ratio of W , 1.029

To get a better check of the formula, therefore, we may select Tests 1A-17A, inclusive, of the Fellows gears which were made from a single melt whose average modulus of rupture was 39,588 lb., substitute this value of s in the formula, and compare with the actual breaking test results. This is done in Table 15.

COMMENTS ON TESTS

The method of testing these gears was employed after due consideration, despite the criticisms made upon it in the discussion of the previous paper. It has the great merit of being both simple and positive. The apparatus is relatively inexpensive and requires no calibration. Since the chief criticisms were directed against the power consumption, meter readings were kept for the entire series of runs. The total power consumption as shown by the recording meter was only 150 kw-hr. The power cost is therefore inappreciable. Were these experiments on wear or endurance, rather than breaking strength, the cost of the power might enter into the problem as a determining factor and indicate the necessity for some such apparatus as that described by Wilfred Lewis at the June, 1914, meeting of the Society.¹ However, with rupture tests, judging from our experience with the way the teeth are thrown at high speeds, it would seem inevitable that fractured cast-iron teeth would fall between the teeth of the steel gear and pinion and wreck the Lewis machine. It is also a question whether the steel gears (unless made of special material and heat-treated), necessarily having the same pitch and pitch-speeds as the cast-iron test gear, would be able to stand up without destructive abrasion under the load which would be required to break the cast-iron teeth. Our own experience (Tests 5 and 11A) leads us to doubt that ordinary, unhardened, steel gears would stand up under these conditions. To carry out our static tooth strength tests, where the load was directly applied by 10-pitch steel pinions, we found it necessary to case-harden these steel pinions.

These experiments, incidentally, give data on the carrying power shown by soft steel gears of the 14½-deg. involute form, 8-pitch, 1⅞-in. face, at pitch speeds ranging up to 1700 ft. per min. (See Tables 1 and 6.) Under the conditions of lubrication here employed the limiting load seems, roughly, to be about 1500 lb. per in. width of face for these gears.

In respect to the ball bearings in the improved testing apparatus, some light is thrown indirectly upon the carrying power of such bearings under rather severe conditions; for it must be borne in mind that the bearings were running, at the instant of rupture, in some cases at as high a rotative speed as 2500 r.p.m. and that the actual suddenly applied

stress upon them, after the teeth began to break and wedge, must have been much greater even than the recorded breaking strength of the teeth, high as this was.

The tests were made in the laboratories of the Leland Stanford Junior University and the writers wish to express their appreciation of the cordial cooperation of the university authorities. Particular thanks are due Prof. W. F. Durand, executive head of the department of mechanical engineering, and to Prof. W. R. Eekart, in charge of the experimental engineering laboratories. Both the Brown & Sharpe Manufacturing Company and the Fellows Gear Shaper Company generously donated the gears necessary for the experiments.

CORRESPONDENCE FROM MEMBERS OF THE SOCIETY

Provisions have been made by the Publication Committee for Correspondence Departments in The Journal as follows: A Department for contributed discussions on papers previously published, or new matter. A Members' Correspondence department including suggestions on Society affairs.

Contributions for these departments are earnestly solicited.

ON MEASURING GAS WEIGHTS

To the Editor:

Mr. Butterfield, in his paper on Measuring Gas Weights (The Journal, August, 1915), is to be commended in his desire to have weight of gas, as well as of air, as a standard. However, it is greatly to be doubted if the universal custom in this connection of always using cubic feet, can ever be superseded. I have made several attempts in this direction, but have found the effort so unpopular that it had to be abandoned. I, therefore, recommend the following as being the nearest practical attainment of Mr. Butterfield's idea.

Amounts of air or gas delivered by fans, blowers, centrifugal or reciprocating compressors, should be given as cubic feet, referred to a fixed pressure and temperature. I have used 14.7 lb. per sq. in. abs. (at sea level and 45 deg. north latitude, if such precision is needed) and 60 deg. Fahr. temperature and have called the quantities so given "cu. ft. of standard air," or "standard gas." 70 deg. and 62 deg. have also been used. It would be desirable if a single temperature could be agreed on.

A cubic foot of standard air or standard gas is a unit of weight just as Mr. Butterfield suggests, but does not involve a serious departure from customary practice. Another definite unit, which is not a unit of weight but which must be kept in mind, is a cubic foot at atmospheric conditions. The weight of such a unit varies with barometer, altitude and atmospheric temperature. The unit most interesting to a designer of a fan or compressor is the cubic foot at the average atmospheric conditions of the point of installation, and this is usually to be understood when cubic feet of a fan, etc., is specified without qualification. The term "cu. ft. of free air" or "free gas" is often used without statement as to whether cubic foot of standard air or cubic foot of air at average atmospheric conditions is meant. Hence, the use of this term without definition should be avoided.

OPPORTUNITY FOR THE ENGINEER IN CHINA

To the Editor:

There are, undoubtedly, many members of the Society who are engaged in business which, under certain conditions, would find a great and remunerative field in the Orient and especially in China. There are many, too, who have never given the matter any serious consideration. To such and all it will pay to turn attention China-ward for a little while and take note of the fast and favorably changing conditions there.

There seems to be considerable interest in Chinese business circles, just now, in the development of China's great, natural resources and their utilization in manufacturing and agriculture. Many inquiries are going about as to the cost of installing and running plants in a variety of manufacturing lines. While these may not materialize into large orders at once, on account of the high rate of exchange against China just now, and from other causes, still it shows a strong movement in the right direction of a tide which, if taken advantage of soon, should lead to good results to all parties concerned, but if neglected can never be regained.

There are several causes which have tended to stimulate this movement:

- a. The European war has cut off China's facilities for borrowing and thrown her back on her own resources for raising funds; this was a good thing for China as it emphasized the value and importance of her rich assets and led many to look for means for using them.
- b. The attitude of a neighboring nation which formerly supplied many manufactured articles to China has stirred up a strong feeling of revulsion which has started up a boycott all over the country, that is not an ordinary boycott, for there does not seem to be any official organization, but rather a spontaneous action which has been an impetus to supply, by home manufacture, as many of the things as possible that formerly were obtained from that country.
- c. The ever increasing number of foreign educated men realize the value of China's resources and are seeking to introduce, to develop them, methods which they have learned of or seen abroad; this is becoming a stronger factor every year, especially in the case of the men returning from the United States.

It is coming to be recognized by Chinese business men that Chinese capital combined with the technical skill and knowledge of America and other advanced countries is what is needed here. As soon as financial conditions are favorable they will be ready to start operations; in the meantime they are gathering facts and figures as much as possible to be ready at the psychological moment. Why should not American manufacturers and machine builders be as astute and far sighted as these Chinese only recently awakened to our civilization?

Although the enterprises that are contemplated may be financed by Chinese capital or a combination of Chinese and American, there will, naturally, be a great opening for American machinery and manufactured goods of many kinds. Many new wants will be created by the new outlook and improved conditions.

In order to get this trade it is very desirable that as many American firms as possible get well represented here so that

each nationality may get well acquainted and familiar before they begin to place orders. If the matter is delayed until the tide begins to turn it will be too late to get the proper benefits because it takes considerable time to get a good footing in such a market. Other nations, keen for the market, have been long established here but are more or less handicapped by the European war.

American goods and methods of business are much appreciated and more of the former would meet with favor if they were only here. Every student who returns from the United States has a soft spot in his heart for that country and its institutions. They form a large part of the foreign educated men. A large percentage of them get into influential places in business or the government and do not forget the good things they saw and learned abroad. Their number increases yearly.

As an aid in promoting trade between America and China, a Sino-American Bank is about to be established with round backing in both countries. The preliminaries have already been settled by the recent Commercial Commission to America. New steamship lines are about to be organized through the same agencies.

American firms represented by Americans are not very numerous in this field yet but a few new ones are beginning to appear, here and there, which is an encouraging sign. It is the height of folly to let American firms be represented here by some other foreign nationality. That course has been taken by some but, to the resident here, the folly is apparent.

Although certain lines of American machine makers are very busy with orders in connection with the war, all those who can do so should turn their attention to the Chinese market, for a while at least, until a good foothold is established. Those who are well established here in the next year or two will have a prodigious advantage over the later comers and would be well repaid for their forethought. The Chinese are keen and reliable business people, are wide awake to the situation and will appreciate any sincere effort to boost things along here.

What would seem like a good proposition for some industries would be for several firms in allied lines to get together and establish a depot for their goods with a fairly good stock on hand for prompt delivery. The ability to show the goods and demonstrate the machinery will go a great way toward filling the order book. What is necessary is to get the goods in the front window where everybody can see them. The country best prepared for eventualities will win out in this race. *It is for Americans to decide whether they will let this opportunity slip through their hands or not.*

In some cases it might be well to arrange with Chinese capitalists to start branch works of American concerns with skilled American technicians in control of the producing side of the business, using such methods and appliances as seem best suited to the conditions here. The materials are here, good mechanics are here and the ready market. This is a field worth investigating. The Chinese are about one fourth of the world's population!

Trusting that this is of interest as coming from one in the field who has the interests of the United States and its industries at heart, I remain,

Sincerely yours,

FRANK A. FOSTER.

Tientsin, China.

FOREIGN REVIEW AND REVIEW OF PROCEEDINGS OF ENGINEERING SOCIETIES

ENGINEERING SURVEY

"In modern German plants for the preparation of powdered coal for firing furnaces, the following is the accepted fundamental principle: simplicity of machinery and apparatus used and accessibility of the whole arrangement. In this respect the German construction differs materially from the American, and even though some typically American crushers, such as the Fuller-Lehigh system, have been adopted in some German plants, as a rule they have not found ready application in that country and for the same reason, the high speed machinery of this type built in Germany itself, has not been much used."

The above is a quotation from an abstract of an article in the important German periodical, *Stahl und Eisen*, an organ of the German Association of Metallurgists. In the common struggle for markets in which it is hoped the American industries will try to get the share to which the resources of the country and genius of its engineers entitle it, it will be of great value to engineers to know the operating conditions and perhaps even the idiosyncrasies of foreign markets.

THIS MONTH'S ARTICLES

In the section, Firing, is reported an article on the preparation of powdered coal and its firing in Germany, describing mainly the so-called Polysius system, viz., a crusher and grinder, the two combined, driving drums and layout of an ideal powdered coal fired plant.

In the section, Internal Combustion Engineering, is reported in brief an interesting investigation on the process of combustion occurring in a hot bulb engine.

Under Steam Engineering are given some data on the comparative commercial advantages and disadvantages of live steam and exhaust steam turbines as applied to plants where large amounts of the latter are freely available. The article is of interest as it shows that although the initial cost of a live steam plant is about 40 per cent below that of mixed live and exhaust steam installations, the saving with the latter is, under the conditions specified, so great that the difference in the initial cost may be recovered in two or three years.

Under Thermodynamics is reported a discussion of what the author terms a thermodynamic paradox, a case where apparently more heat is recovered than is actually put in in coal at the generating end of the plant. As a matter of fact, Lord Kelvin, many years ago, predicted its possibility on theoretical grounds.

An investigation of fusible tin boiler plugs is reported from a paper published by the American Chemical Society. The outstanding points of the investigation are that unless the fusible plug is properly made, it may become a source of danger instead of being an element of safety. It was further found that pure Banca tin was not and is not being used in the filling of a considerable number of plugs on the market, but while no change would be detected in samples of pure tin under certain conditions of treatment, when lead was present, the filling, with same treatment would become

porous at a comparatively low temperature, while in other cases tin oxide formed, having a higher temperature than the steel of the boiler plates themselves. From this investigation it appears, therefore, on the whole, that the purity of the metal used in the filling ought to be given much more attention than has been the practice hitherto.

A phenomenon known as a "hydraulic jump" is discussed in a paper before the American Society of Civil Engineers. The author discusses mathematically the relation between the depth, head and maximum discharge of controlling sections and indicates the nature of the hydraulic jump and the conditions under which it originates.

Several papers are reported from preliminary publications to the meeting at Atlantic City of September 28 to 30, 1915. Methods of reclamation of magnesium from turnings were discussed by John Carlson. S. Trood presented a paper on sherardizing, in which he investigates the process of sherardizing from the point of view of ionic relations between vapors of metals present in the sherardizing drum and shows the great influence of pressure in the drum, uniformity of zinc dust and heat and quality of iron. The paper is of considerable practical value and throws a good deal of light on this still somewhat incompletely understood process. The manufacture and use of alloy of vanadium and aluminum is discussed by W. W. Clark. It is shown that the alloy can be easily made, but that its field of application is rather limited. S. W. Parr gives the chemical composition of an acid resisting alloy. Its acid resisting properties appear to have been fully established, but methods of casting seem to still require further developments.

Two papers on asphaltic and bitulithic pavements are reported from the Journal of the Association of Engineering Societies. In connection with one of these papers is reproduced a table giving a summary of cost data for various kinds of pavements (collected in the State of Oregon).

In an abstract from a paper before the British Association are given some data on testing tool steels and in particular on a dynamometer used for such tests.

James J. Guest, in a paper abstracted in the Journal of the Institute of Mechanical Engineers, gives an interesting presentation of the theory of grinding, with reference to the selection of speeds in plain and internal work. From the same source has been made an abstract of a paper by H. Mowson on struts and tie rods in motion, of interest because it shows that formulae which have been derived for forces in stationary struts are only special cases of those obtained for rods in motion. Among other things, the author discusses in detail the case of a particular locomotive coupling rod which broke while in service and shows that the stress in the rod increases very rapidly as the speed of the engine increases, and that at very high speeds an increase of steam pressure does not appear to have as disastrous an effect as an increase of speed.

In a paper on safety valves before the Scientific Society of the Royal Technical College, Glasgow, D. MacNicol reports on the work which was done by the British builders on the design of safety valves for oil fuel vessels. It is of interest to point out in this connection that (*The Journal*, August 1915, p. 481), the German manufacturers, who like-

wise use a formula (the Caro equation) derived from coal burning boilers, found that their formula did not take care of the generation of steam in oil burning plants.

Those who are interested in the utilization of solar energy are referred to the brief abstract of a paper on this subject by A. S. E. Ackerman before the Society of Engineers (London).

FOREIGN REVIEW

Firing

POWDERED COAL PREPARATION AND FIRING IN GERMANY.

In modern German plants for the preparation of powdered coal for firing in furnaces, the following is the accepted fundamental principle: simplicity of machinery and apparatus used, and accessibility of the whole arrangement. The operation, which must be entirely automatic, must be carried out by as small an amount of reliable machinery as possible, so that it can be operated without trouble by unskilled labor. The

and with certain advantages; otherwise, however, the saving effected by their use will be more than eaten up by interruptions in the operation of the plant.

In the modern German plant nearly everywhere one finds slow running grinders with a large area of crushing, mainly of the ball and tube mill type. The larger amount of power consumption as compared with high speed machinery does not particularly matter here. Ball and tube mills are as a rule located one over the other, so that the grist produced by the ball mill can go directly to the tube mill and be converted into fine powder.

In order to improve the screening action, several types of ball mills have been placed on the market; for example, the so-called Cementor mill of Polysius, Dessau, Germany. Contrary to the usual practice in ball mills, this construction has unperforated crushing plates, these plates being located be-

FIG. 1 A, CEMENTOR COAL CRUSHING MILL; D, POLYSIUS DRYING DRUM

path of the material should be as short as possible and as close as possible to a straight line.

In German plants particular attention is directed to simplicity of construction of the grinder, in which respect the German construction differs materially from American, and even though some typical American crushers,—e.g., the Fuller-Lehigh,—have been adopted in some German plants, as a rule they have not found ready application in that country, and for the same reason, the high speed machinery of this type built in Germany itself has not been much used.

Where the plants using powdered coal have efficient repair shops and skilled mechanics available, oscillating crushers and similar apparatus can be used without much difficulty

tween the walls in such a manner as to form stages with each other. With this construction, the grist is forced to run through the entire path of the grinding, passes over the sieve and is then partly returned in a uniform manner into the grinding drum. Fig. 1A indicates diagrammatically the fundamental principle of this design, while Fig. B shows the combination of a Cementor mill and a tube mill.

The high cost of foundations which such an arrangement involves, and the effort to simplify still more the grinding, led to the design of a machine which could carry out the crushing and fine grinding in one continuous series of operation. This resulted in the design of a combined crusher and grinder, forming one cylinder, a design particularly adapted for use in steel mills because of its extraordinary simplicity. This type of machine, called "Solo" mill, is likewise built in Germany by G. Polysius, Dessau (Fig. C), and consists of a seamlessly welded sheet cylinder running in circular bearings. This cylinder is divided by a wall into two chambers, one the crushing chamber with hard steel plates and steel balls, and the other the fine grinding chamber with Silix lining and quartz stones. The crushing chamber is surrounded with screens, and is enclosed in a sheet steel jacket, and can crush pieces as large as a man's fist. This grist then falls through slots at the end of the crushing chamber upon screens over which it travels, just as in the Cementor, to the admission side of the grinding mill. What remains over the screen is carried back into the crushing chamber while that which passes through the screen is delivered to the grinding chamber and handled there.

As compared with the oscillating and Fuller mills, this design has the advantage of handling pieces to the size of

a man's fist; as compared with mills which require special separators, as in the Raymond crusher, there is the advantage that the Solo mill uses no cyclones, etc. In addition to that, there is the very important consideration that this type of mill insures to a very large extent against the occurrence of fires and explosions where the material handled has to be transferred from one apparatus to another, it is very difficult to provide against its escape and the formation of inflammable or explosive mixtures with air. In this case,

as shown in Fig. D. The hot gases from the grate *a* play around the drum and pass through the interior of it and dust chamber *b*, into the smoke stack or the exhauster, as the case may be. The gases when they reach the interior of the drum have so low a temperature that no gasification of the coal can take place. With very fine coal, special arrangements are provided to prevent the dust being carried away with the gases. The dimensions of the dust chamber are selected in accordance with the kind of coal to be dried.

B

E

FIG. 1. B, COMBINATION OF CEMENTOR MILL AND TUBE MILL; C, SOLO MILL; E, COAL HEATING; G, SUCTION DUST FILTER

this source of danger is eliminated to a large extent, and the author states that explosions have never occurred in mills of the Polysius type. The objection is often made to crushers operated with screens on account of their rapid wear; in the Solo mill these screens consist of perforated steel sheets of high resistance, in addition to which the construction is such that large pieces of iron that cause most of the wear cannot reach the screen.

As a rule, the Polysius Company build their drying drums

The brickwork is sometimes laid funnel-shaped at the bottom, so as to allow the dust settling on the walls, to fall into the container below. The drum may also be very conveniently heated by blast furnace or coke oven gases. The system of heating proper, as shown in Fig. E, is derived from that used in America.

Double worms are provided for carrying the coal dust from the storage bins, the windings of the two worm spirals being staggered with respect to one another, which ensures

a uniform supply of coal dust. The speed of rotation of the conveyor is adjustable by means of the Polysius governor (not shown in detail), which can be made to act simultaneously on the throttle in the air supply so as to vary the amount of blast in proportion to the increase and decrease of the coal dust handled. A special indicator is also provided, permitting the reading of the amount of coal dust used. The suction piping of the high pressure fan is connected with the cooling drum or such device as is used for conveying the sintered or roasted material; it delivers air of combustion preheated to from 300 to 400 deg. cent. (572 to 752 deg. Fahr.). One part of this air is taken in by suction through the exhanstor, while the rest goes through the smoke stack. In rotary cement kilns, an excess of air is usually admitted and the amount of air is governed by a throttle located at the smoke stack.

by means of a suction fan. Similar filters have been recently introduced in iron plants to clean blast furnace gases. The author points out that the use of such devices for cleaning air and the protection of workmen considerably increase the cost of installation of German plants as compared with American plants, which fact, however, ought not to be weighed against the safety of the workmen and their improved state of health. (*Neuerungen in Kohlenstaubfeuerungen, Stahl und Eisen*, vol. 35, no. 38, p. 965, September 23, 1915, 6 pp., 9 figs. d.)

Internal Combustion Engines

PROCESSES OF COMBUSTION IN A HOT BULB ENGINE,
Erich Weisshaar.

Experimental and theoretical investigation of the processes of combustion in a hot bulb engine.

FIG. 1 F, IDEAL LAYOUT OF A POWDERED COAL FIRED PLANT

Fig. F represents what the Polysius Company considers an ideal coal drying and grinding plant, demonstrating an effort to attain the greatest accessibility of parts and the shortest paths of travel for all material handled. The plant shown in the diagram grinds coal dust for four rotary kilns, for which it employs two drying drums and two Solo mills with a total output of about 145 tons per day.

German law prescribes the installation of efficient air cleaning apparatus for the protection of the health of workmen. The suction dust filter used in the described plant is shown in Fig. G. The air, with such dust as it may contain, is taken from all the machines of the coal grinding mill, and driven through a center passage and then through the filter

The increasing importance of the hot bulb engine, its better design and application of the two-stroke cycle, as well as the increasing availability of cheap fuel oils for use in it, have very rapidly extended the field of application of this type of engine, but the knowledge of the processes of combustion inside the cylinder have not kept pace with its practical use. In the present article, the author attempts to answer the question as to how this most important process, that of combustion, occurs in a hot bulb engine.

The engine investigated was a stock type of 2-cylinder crude oil marine engine of the Maschinenbau A.-G. vormals Ph. Swiderski, adapted for land use by reduction of the speed of rotation. It was loaded very uniformly by a drive

to a centrifugal pump, and was fed with tar oil and some gas oil. Only very little water had to be injected. The amount of tar oil and water was regulated by a governor, while the addition of gas oil remained constant. The engine had the following dimensions:

Cylinder 1	
Diameter.....	322 mm (12.67 in.)
Stroke.....	381 mm (14.99 in.)
Cylinder 2	
Diameter.....	320 mm (12.59 in.)
Stroke.....	379 mm (14.91 in.)

The opening of the exhaust port begins at 0.72 of the piston stroke: average speed of rotation, 261 r.p.m.

The diagrams show quite material oscillations in the expansion line which were equalized by placing above and below the oscillation, enveloping curves and plotting an average curve between these two. Such a method is permissible because it may be assumed that we have to deal here with damp free oscillations. Four diagram sets of ten 2-strokes each, were carefully measured for each cylinder and all

and zero lines on the other hand (This work is expressed here in calories).

On the other hand, because of cooling during the same period of the motion of the piston, there is a loss through cooling of quantity of heat q_w , to which has to be added the heat loss q_r , due to the fact that a part of the oil is taken out by the exhaust, incompletely burned, in the form of carbon monoxide and incandescent soot. Since there must be an equilibrium between the quantities of heat added and taken out:

$$J_o + Q = J_i + A + Q_w + Q_r$$

in this equation J_o and J_i can be determined from the gas temperatures T_o and T_i , provided the weight of gas G in the cylinder is known (The specific weight of gas is here assumed to be variable).

For the determination of heat losses, q_w , due to cooling, the author uses an expression which he previously derived for the case of a Diesel engine. The determination of the weight of gas present in the cylinder during the comparison and expansion is a rather difficult experimental proposition (*Der Verlauf der Verbrennung im Glühkopfmotor*, Erich Weisshaar, *Der Oelmotor*, vol. 6, no. 5, p. 151, August 1915, 6 pp., 4 figs., et).

Steam Engineering

1250 KW MIXED PRESSURE TURBO-GENERATOR, F. Schulte

Description of a mixed pressure turbo-generator and calculations showing the commercial advantages and disadvantages of live steam and exhaust steam turbines under certain predetermined conditions.

In this instance, there was an electric generating plant at one of the two mines of the same company, but with the growth of business, its output ceased to be sufficient. There was available at the plant approximately 11,000 kg. (24,200 lb.) of exhaust steam per hour, and at a consumption of 16 kg. (35.2 lb.) per kw-hr., approximately 700 kw. could be obtained from this source. About 1000 kw. were considered necessary; hence, about 300 kw. would have to be generated by live steam if a mixed pressure turbine were used. It is clear that the selection of type of turbine was to be determined principally by economic considerations.

An investigation showed that the first cost of pure live steam turbines, with equipment and buildings, would be

FIG. 2 AVERAGE DIAGRAM OF PROCESSES IN A HOT BULB ENGINE

combined, on an enlarged scale, into a single average diagram, Fig. 2. The maximum pressure could not be determined with certainty from the enveloping curves, and it was plotted in such a manner that the corresponding point on the heat diagram would not have an impossible location. The average diagram shows an average pressure of 2.27 kg. per cm. (32.28 lb. per sq. in.), so that the indicated output amounts to 81 h.p. Since the efficiency of the pump and its ability were known only approximately, the effective output could only be estimated, and was taken to be 60 h.p.

The author discusses in detail the process of combustion, in the following manner:

When the piston is at the upper dead center, there is contained in the compressed mixture of exhaust gases and air a quantity of heat J_o . To this has to be added the quantity of heat, Q , contained in the oil and becoming free on combustion. At the point 7', when the exhaust port is open, there is contained in the gas a quantity of heat J_i . On the way from the dead point to the opening of the slot, there is delivered a quantity of work, A , represented by the area between the ordinates O and $7'$ on one hand and the expansion

155,000 marks (roughly \$38,000) in addition to which another boiler plant, costing 49,500 marks would have to be installed, thus bringing up the first cost to about 204,500 marks.

A mixed pressure turbine, with all its equipment and buildings, would cost 255,000 marks, or about 50,000 marks more than a live steam turbine and the additional boiler plant. On the other hand, the operating costs, under the assumption that the turbine would run 16 hours per day, under full load, and that during this time there would be available 700 kw. exhaust steam, would be as follows:

<i>A—Live Steam Turbine</i>		Marks
1. Interest and depreciation on first cost at the rate of 10 per cent.....		20,470
2. Attendance, 16 hr. per day and 300 working days per year.....		1,920
3. Cost of live steam, 16 hr. per day, 300 days per year, with steam consumption of 9 kg. (19.8 lb.) per kw-hr. (under the assumption that 1000 kg. would cost 160 marks).....		69,120
4. Lubricating oil		490
5. Repairs		1,400
6. Cost of attendance on the three additional boilers		2,800
Total operating cost.....		96,200
<i>B—Exhaust Steam Turbine</i>		Marks
1. Interest and depreciation of plant at the rate of 10 per cent.....		25,500
2. Attendance, 16 hr. per day, 300 working days per year.....		1,920
3. Cost of live steam for 300 kw., 16 hr. per day, 300 days per year (under the assumption of 9.5 kg. per kw-hr.).....		21,880
4. Lubricating oil		500
5. Repairs		1,000
Total operating cost.....		50,800

Which shows that the operating cost of a live steam turbine is approximately 45,400 marks per year higher than the cost of the exhaust steam turbine. Actually, however, the saving in operating expenses with the exhaust steam turbine will be considerably lower, partly because some of the exhaust steam would be utilized for the preheating of feed water and partly because the exhaust steam from the hoisting engines is available at irregular intervals and may thus to a certain extent have to be exhausted into the atmosphere.

The paper describes in detail the construction of the turbine condensing plant and steam accumulator and gives as well data of tests with pure live steam and pure exhaust steam as driving media. Tests have shown that the steam consumption either way was below the guaranteed amount and that the expectations from the economic point of view were satisfactorily fulfilled. A striking indication of the saving through utilization of the exhaust steam is given in the fact that before the installation of the turbine, about 3000 to 4000 marks (\$750 to \$1000) worth of current was purchased from outside sources, while after the turbine has been installed, not only has this entire amount been saved, but an opportunity for a source of profit of about 3000 marks (\$750) from the sale of current was opened, while the steam consumption of the mine remained at the former

level. (*Mischdruck-Turbogenerator für 1250 kw. der Zeche Neu-Islerlohn I der Harpener Bergbau-Akt. Ges., F. Schulte, Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 39, p. 785, September 25, 1915, 6 pp., 6 figs., dp.)

Thermodynamics

A THERMODYNAMIC PARADOX.

The paradox which the author considers, exists in the fact that under certain conditions, the total amount of heat developed in machinery from a pound of coal, appears to be larger than that initially contained in the coal. The possibility of this was first pointed out by Professor Thompson (Lord Kelvin) and since utilized in the refrigerating system of Altenkirch (see the Journal, October 1913, p. 1574).

The author questions whether a refrigerating machine can be used as a heat generator, apart from the consideration of its output of cold, and shows that if this be done, apparently an excess of heat is produced. The whole point lies in the fact that refrigerating machinery may produce not only cold in the evaporator, but also heat in the condenser. If the heat generation be considered the main purpose of such a machine, then, with a small temperature difference, an amount of heat could be made available in excess of that consumed in the motor driving it. The situation is as if the power transferred to the refrigerating machine had the properties of a ferment. The output of cold and heat is not equivalent to this power, the latter giving simply the impetus of an incomparably greater heat transformation.

In two mechanically connected cycle processes, a large temperature difference with a small amount of heat in the first process, creates a large output of heat with a small temperature difference in the second process, in accordance with the following diagram:

There is no doubt, of course, that the heat generated in the compressor is equivalent to the amount of power consumed. Hence this amount of heat is small, but when steam is liquefied at a higher temperature, a large amount of latent heat is freed (the amount which was tied up at the lower temperature in the evaporator) and it is this amount of heat which is of determining influence. As an example, the author gives the following particular case:

A good steam engine requires 0.75 kg. (1.6 lb.) of coal per effective h.p.-hr. One h.p.-hr. is equivalent to 637 calories. If one takes the heating value of coal to be 5600 calories (10,800 B.t.u. per lb.), then 4200 calories have been used up and the utilization of heat may be taken to be only 15 per cent. An ice making machine has been tested in this respect, and produced at 14.75 effective h.p. in the condenser, 7250 calories per hr., or 4915 calories per effective h.p.-hr., so that with all losses, there has been actually obtained with an expenditure of 4200 calories, an output of 4900 calories (with a Diesel engine, 4900 calories can be obtained with an expenditure of only 2200 calories).

(Of course the above does not really conflict with the accepted laws of the mechanical theory of heat, as has been

previously shown by Lord Kelvin. Editor's note) (*Ein "Paradoxon" aus der mechanischen Wärmetheorie*, Johs. A. F. Engel, *Dinglers polytechnisches Journal*, vol. 330, no. 15, p. 289, July 24, 1915, 2 pp., t.)

Miscellaneous

LAWS OF DETERIORATION OF TELEGRAPH POLES, Fr. Moll.

The paper discusses the laws of deterioration of wooden poles used for the suspension of electric wires, in particular, telegraph poles. The author points out that the entire matter of impregnation engineering is still in its initial stages of development, and the subject of the efficiency of impregnating materials has been investigated only to a limited extent.

The main question in this connection is, what is the relation between the chemical constituents of the impregnating materials and their efficiency as inhibitors of decay. The work of Netzsich has shown, for the group of salts of fluorine, that salts in the solution of which free ions of fluorine are developed, have an efficiency practically proportional to the contents of fluorine in the salt. The present writer has established a similar relation for a number of salts of zinc with regard to the contents of zinc metal, and it appears, therefore, that the inhibiting action is dependent either upon the presence of acid ions or metal ions. If, however, both are at work, the investigation becomes much more difficult and more extensive experimentation is required in order to establish the law of inhibitory action. It may here be mentioned that most of the so-called "data of tests" published as advertising matter by various manufacturers of impregnating materials can be considered as entirely worthless in this connection.

In the absence of sufficient reliable data on the efficiency of impregnating materials, the best source of information appears to be statistical data on the life of various types of telegraph poles. In Germany such data have been collected since 1850 and published at various periods, in particular, by Christiani in 1905. These data have shown that of all of the processes of impregnation those using kyanization and impregnation with tar oil, have given the best results. The economic value of impregnating poles may be determined in accordance with the following formula:

$$\text{Economic efficiency} = \frac{\text{average cost per annum} = \frac{\text{cost of operation}}{\text{average life}}}{\text{average life}}$$

The cost of operation includes of course both the impregnation and the delivery of the poles to the spot, and is, as a rule, given by the accepted bids, but the average life of the pole is, to a greater or less degree, an unknown quantity. Some data are given in the German publication, *Archiv für Post und Telegraphie*, 1913, p. 229, where the life of poles of various kinds of wood, with and without impregnation, is given as compiled from data published by telegraph administrations all over the world. From this publication the writer cites Table 2.

On the whole, the author comes to the conclusion that the life of impregnated poles may be predetermined by the application of the usual laws of probability and that the destruction of wooden poles through decay follows the usual probability curve. He gives for it the following equation:

$$y = \frac{0.564h}{e^{h^2 x^2}}$$

in which x and y are, as usual, unknown quantities, e is the basis of natural logarithms, h , a constant which may be denoted as a parameter and has a different value for each average period of life of the post; for any average life of post, h may be expressed in the following manner:

$$h = \frac{0.177 \times 5}{\text{average life}}$$

Thus, for the average life of 20 years, which is about what is obtained from kyanization, and poles impregnated in a

FIG. 3. ACTUAL AND PROBABILITY CURVES OF DECAY OF TELEGRAPH POLES

proper manner with tar oil, the curve of probable exchange of poles has the following shape:

$$y = \frac{0.564 \times 0.096}{e^{0.096^2 \times x^2}} = \frac{0.0541}{e^{0.00912 \times x^2}}$$

The author gives the following two curves: curve 3.4 indicating the average line of necessary exchange derived from 40 statistical compilations. This curve was recomputed on the basis of an average life of ten years. One division on the abscissa line corresponds to one year in the statistical data and the total length of the abscissae is 20 years; the

ordinates indicate the approximate amounts of exchange of poles in the years given by the abscissae, one division of the ordinates giving one per cent of the total number of poles. For purposes of comparison there is drawn in full lines over the curve of actual exchanges, the curve of probability.

Fig. B gives the curve of probability for a value of b , corresponding to an average life of twelve years, 16.5 years and 20 years. Only the left part of the symmetrical curve is drawn. In the abscissae, one division corresponds to one year of life in the ordinates, which division corresponds to 1 per cent of the total number of poles. The ordinates give, therefore, the accepted approximate yearly exchange of poles. (*Die Gesetzmässigkeiten im Abfall hölzerner Masten für elektrische Leitungen*, Dr.-Ing. AMERICAN CHEMICAL SOCIETY

Journal of Industrial and Engineering Chemistry, vol. 7, no. 10, October 1915, New York City.

AN INVESTIGATION OF FUSIBLE TIN BOILER PLUGS, G. K. Burgess and P. D. Merica.

The investigation was prompted by the explosion on May 11, 1914, of a boiler on the steamship *Jefferson*, which subsequent investigation showed to have been due to low water and consequent overheating of the boiler plates. This should have been indicated by the fusion of the filling of the tin fusible plug in that region, but the plug was found to be unmelted and superficially sound. When the plug was sent to the Bureau of Standards for investigation and there was sawed open longitudinally, it was found to contain only traces of the original tin imbedded in a dirty greenish matrix consisting largely of tin oxide. This oxide has a melting point of about 2900 deg. Fahr., and it was distributed in such a form and quantity that it held the pressure of the boiler. As a matter of fact, instead of being an easily fusible mate-

oxide or copper oxide. It appears practically certain that this oxidation occurred in service and that the oxide was not poured in with the tin generally. In order to determine the relation between the temperature values found and the purity of the tin in the fillings, the melting points of a number of the old plugs, as well as new ones, were taken and chemical analyses made of the fillings showing abnormal melting points. It was found that Banca tin was not and is not being used in the filling of a considerable number of plugs. Of 35 plugs analyzed chemically, only six fillings showed 0.20 per cent or less impurities, or only six out of the 35 were composed of any variety of high grade tin. The principal impurities were lead or zinc. Of about 70 melting point determinations made on used and new plugs, only eleven gave values within 0.5 deg. cent. of the melting point of pure Banca or Straights tin.

Plugs with fillings that had a low melting point and contained zinc, showed what the author calls "network" type of oxidation, which he explains by the constitution of the zinc-tin alloy and its behavior on cooling. In the zinc-tin alloy of certain particular types, the tin crystals are surrounded by an envelope of zinc. If this alloy be brought in contact with a corrosive aqueous solution, the latter will attack the zinc first, eating its way into the plug through the grain or crystal interstices, and the tin filling finally becomes honeycombed in structure. The corrosion of the tin itself may start from these crystalline canals and the oxidation produced remain, forming gradually the oxide network structure already referred to. Alkaline waters, such as would be produced by over addition of soda boiler-water softener, attack zinc even at ordinary temperatures and probably corrode tin at high temperatures. The temperature of the water and plug will determine to a greater extent the rapidity of the progress made by the oxidation.

A number of new plugs, as well as plugs made up at the Bureau, containing definite amounts of impurities, were subjected to the action of water at high temperatures to determine what would be their behavior under these known conditions. For this purpose, the plugs were put in a copper autoclave and heated for various periods at a temperature of from 180 to 195 deg. cent. in either tap or distilled water. Of 14 new plugs, heated for 195 hours and 20 new plugs for 140 hours in tap water, only three showed any change whatever. These were all from one manufacturer and contained lead in varying amounts. All were somewhat distorted and covered with spongy abrasions. Whereas no lead could be detected in the microstructure before heating, after heating the lead had coalesced as an enveloping boundary to the tin crystals.

The plugs containing zinc and lead in amounts equal to or above 0.5 per cent were generally found cracked after heating for about 500 hours at from 350 to 380 deg. Fahr. In some cases, particularly when lead was present, the filling had become porous due to the melting out of the low melting eutectoid, which in this case melts around 170 deg. cent. (330 deg. Fahr.). *No change could be detected in the samples of Banca or Straights tin caused by this treatment, other than a slight surface oxidation.*

The article discusses briefly the testing of the purity of zinc. The most important conclusion to which the author comes is that the use of pure tin would probably eliminate danger of oxidation of plugs in service (6 pp., 7 figs., ep. A).

TABLE 2 AVERAGE LIFE OF TELEGRAPH POLES OF VARIOUS WOODS

Chestnut	10
Cedar (N. America)	15

rial, it would not have melted until the bronze of the casing and even the steel of the boiler had melted, and instead of being a factor of safety, it was a menace.

As no data as to the worth of fusible tin plugs of this sort were found in technical literature, the steamboat inspectors were requested to send in to the Bureau more plugs for testing purposes and in answer to the request, about 250 plugs were received, of which about 100 had been in service varying from four to twelve months. These plugs represented the products of some 105 firms.

The plugs were classified according to the degrees of deterioration. Some were found to be partially melted away; others with fillings expanded in service, corroded or pressed in at the water side. In some plugs, non-metallic formations or incrustations were found in the filling, such as zinc

The Hydraulic Jump, in Open-Channel Flow at High Velocity, Karl R. Kennison (abstracted)

A Study of the Depth of Annual Evaporation from Lake Conchos, Mexico, Edwin Duryea and H. L. Haehl

THE HYDRAULIC JUMP, IN OPEN-CHANNEL FLOW AT HIGH VELOCITY, Karl R. Kennison

When water is discharged into a flume through a contracted gateway and under a considerable head it sometimes continues to move in a thin sheet at a high velocity along the bottom of the flume for several hundred feet. Then it suddenly becomes turbulent and forms what is called a "hydraulic jump," the surface level down stream from this point being very much higher than that of the approaching high velocity discharge. Another case is when water flows over an ogee dam and out on a smooth apron; then it sometimes continues in a thin sheet having a surface level far below the normal level of the river until it suddenly changes into a tumbling mass rising to the normal river level by this hydraulic jump. This phenomenon is sometimes of great practical importance in connection with the design of dams; for example, in one case it was desirable that the back roll or hydraulic jump should not be allowed to extend far off down stream below the foot of the ogee, from a concrete apron which protected the clay river bed from scour. In another case, it was desirable that the hydraulic jump should not extend down stream so far as to interfere by its violent surges with the draft tube exits of a power house.

The author discusses mathematically the relation between depth, head and discharge and the maximum discharge of controlling sections. He comes to the following general conclusions:

In the case of water flowing in an open channel on a steep gradient there are certain controlling sections which throttle the flow and determine the quantity of the discharge. If the contraction which causes this throttling of the flow is sufficiently gradual, for example, a submerged dam with smooth gradual approach and getaway, it can be shown that the depth of water at this point is theoretically two-thirds of the total head measured from the channel bottom or dam crest up to the hydraulic gradient, and the discharge per foot of length should be $3.09 H^{3/2}$.

At other points than at the controlling section, the depth of water is not necessarily determined by the quantity discharged and the available head, but also by the channel conditions. The upper stage is the normal level in an ordinary stream and for very low velocities is practically coincident with the hydraulic gradient. The lower stage is that ordinarily taken by water discharged at high velocity from an orifice or below a spillway dam. In other words, it can be shown that in any open channel, except at controlling sections, there is in addition to the existing water level another level at which the same quantity of water might be flowing with equal steadiness and under the same head or elevation of hydraulic gradient.

In the case of smooth, undisturbed flow the stream must stand at one of these two levels; that is, water flowing in a smooth channel of a uniform section must continue to flow at its existing stage, whichever one that happens to be, until for some reason it encounters a controlling section where the two alternative stages merge into one and the depth is

two-thirds of the total head. Below this controlling section, the two possible stages again separate. At such a point as this, the water level may change without disturbance or interruption of the steady flow from one stage to another, or may continue in the same stage. Thus the water behind the spillway dam is approaching at the upper stage and just below the dam it flows away at the lower stage. The change occurs smoothly over the dam where the two stages are merged into one, but if the dam is submerged by back water almost as high as the up-stream pool, the surface may simply dip down locally at the dam where the depth is two-thirds of the head. In such a case the upper alternative stage is maintained throughout, below as well as above the dam. Usually the presence of the controlling section tends to conceal the existence of the two alternative stages, but water flowing at the lower high velocity stage and suddenly encountering obstructions which tend to destroy its velocity, may rise suddenly, and with considerable disturbance and eddying, to the more stable upper low velocity stage, thus forming what is known as the hydraulic jump.

The only energy lost in this phenomenon is that used by accompanying disturbance and eddying, as the jump proper merely converts kinetic into potential energy. Ordinarily, however, when appearing below a spillway dam, the hydraulic jump is accompanied by such violent disturbance and eddying that the total surplus energy in the water may be destroyed in this way (15 pp., 13 figs., *mA*).

Reclamation of Magnalium from Turnings, John Coulson (abstracted)

RECLAMATION OF MAGNALIUM FROM TURNINGS, John Coulson

The use of magnalium metal (an alloy of aluminum and magnesium) for finished castings has increased to such an extent that the recovery of the metal from the turnings has become an important factor. The difficulty of the operation consists in the fact that the oxidation of finely divided magnalium is extremely rapid, and, unless some process of agitating the melted material is applied, the oxide film will prevent it from fusing together.

Fluxes composed of chlorides and fluorides of the alkaline earths have been used with some success, as well as cryolite. The latter, however, is objectionable, since it attacks silicon and graphite crucibles. To avoid the difficulties involved in the use of the various fluxes, a method has been developed of using inert gases; hydrogen has been found to give the best result. As a fluxing agent common salt was used. The turnings were boiled for a few minutes in a 4 per cent salt

solution, which was then poured off and took with it the objectionable scum. The gas pressure was applied through a pipe overhead. It was even found that the turnings could be melted in an open crucible after they had been boiled in a solution of slightly fluxing salt. The damp turnings were turned into a crucible heated to 900 deg. Cent., and by mechanical means were forced to coalesce as they melted, each addition of turnings being thoroughly puddled until the mass became uniformly viscous. After the last puddling operation, the charge was left standing in the hot crucible for ten or fifteen minutes which gave the oxide time to rise to the surface, where it was held while the clean metal was poured from underneath.

The metal recovered from the turnings contains some oxide and is therefore not as good as the original magnalium, but its physical characteristics can be improved by the introduction of a deoxidizing agent, e.g., 1 per cent of metallic calcium or $\frac{1}{2}$ per cent of calcium aluminum silicide (7 pp., d).

SHERARDIZING, S. Trood

The paper presents an investigation of the process of sherardizing, an explanation of the usual lack of uniformity of results and directions for making the results uniform and for reducing the time required for the process. A brief history of the process is given in the introductory paragraphs.

The author shows that in the sherardizing drum there are microscopically small globules of zinc vapor surrounding the particles of zinc oxide and charged electrically. In addition to that, there are gases emanating from iron and also carrying ionic charges. Iron and zinc have different potentials. As a result, discharges must occur which, in their turn, precipitate solids from gases—that is, zinc and iron.

If that is so, the atmospheric pressure will have a considerable effect on the process as the vapor tension of the gas will vary with the pressure and the gases will be more readily given off in vacuum. To prove this, the author created a vacuum in a small sherardizing drum, and results were produced in ten minutes in a vacuum which would require six hours at the same temperature under atmospheric pressure. Since electric potential is higher for pure gases than for mixtures of gases, it is of advantage to have the zinc dust and iron in as pure a state as possible. The author comes to the conclusion, therefore, that uniformity of zinc dust, uniformity of heat, and the quality of iron are of great importance as affecting the uniformity of results. In addition to this, the proper time of sherardizing is an essential factor.

The best method of preparing the surface to be sherardized is shot air blasting. Sand blasting is not good because particles of sand penetrate the pores of the iron. Pickling requires great skill, and must be done very carefully, as often sulphates and phosphates are created on the surface and are hard to remove, in addition to which traces of salts, alkalis and acids after pickling may produce a retarding result when heated, so far as the ionic charges are concerned.

In the zinc dust, zinc should not be below 85 per cent, zinc oxide not below 8 per cent, and lead should be kept down to about 1.25 per cent.

Experiments have shown that when the percentage of lead is too high, lumpy deposits will appear on the plain sherardized surface. The zinc dust particles must be kept

uniform in size. After deposit of the zinc begins, the thickness of the deposit depends solely upon the time. The coating which is being deposited when the temperature is going up is the most dense and durable. Next in quality will be the coating at uniform temperature, and the poorest when the temperature is going down (11 pp., ep).

THE MANUFACTURE AND USE OF ALUMINO-VANADIUM, W. W. Clark

The paper discusses the manufacture and use of an aluminum-vanadium alloy intended for use as a carrier of vanadium in the non-ferrous alloys.

The alloy is manufactured in the following manner: Ingot aluminum is melted in a graphite crucible provided with top and bottom holes. The thermit mixture of vanadic oxide and granulated aluminum is then ignited on top of the molten metal. After it has all been reduced, the mass is stirred and the metal tapped. Aluminum-vanadium alloy can also be manufactured without difficulty in the electric furnace. The alloys are not pure as they contain a fraction of one per cent of iron in addition to small amounts of silicon and carbon.

There are several difficulties encountered in the use of aluminum-vanadium alloys. Aluminum in an alloy of copper and zinc, or copper, zinc and nickel, tends to make the metal brittle when rolled. If a metal is not perfectly deoxidized, aluminum oxide may be found enclosed. In drawing metal such as cupro-nickel, aluminum is objectionable, as the metal hardens too quickly. The author believes therefore that nickel and manganese alloys of vanadium may be more suitable. He also considers it very doubtful that small amounts of vanadium will increase the tensile strength of non-ferrous metals beyond that due to its powerful deoxidizing properties, and vanadium should not be used as a scavenger, as there are a number of as good and cheaper ones available. If, however, used with metal previously cleansed, vanadium in small amounts does increase the elongation (8 pp., p).

THE DEVELOPMENT OF AN ACID-RESISTING ALLOY, S. W. Parr

The paper discusses the development of an alloy which, in addition to being able to withstand the corrosive action of acids and gases, would be suitable for use where density, strength and working properties are essential, besides being considerably cheaper than platinum and available in larger amounts.

This latter condition necessitated the production of this material from base metals. After a considerable amount of experimentation, an alloy has been developed such that six discs made of it have shown no weighable loss after contact with 25 per cent nitric acid for twenty-four hours. The chemical composition of this alloy is rather complicated:

Cu	6.42
Mn	0.98
Si	1.04
W	2.13
Ni	60.65
Al	1.09
Fe	0.76
Cr	21.07
Mo	4.67
Total.....	98.81

It has been found, however, that each additional element lowers the melting point of the alloy, and reduces the tendency to form an open texture or coarsely crystallized structure.

The melting point of the alloy is approximately 1300 deg. cent. When thoroughly liquid, the alloy pours readily and fills the mold perfectly, but the freezing point is so quickly reached that feeding of the casting from risers to make up for shrinkage is practically impossible, while the shrinkage is so excessive that cracks and hollow spots are very difficult to avoid. The material works in a lathe about the same as tool steel. So far, the attempts to draw the alloy into wire and roll it into sheets have been only partially successful. The tensile strength of the cast metal is approximately 50,000 lb. per sq. in. (7 pp., 2 figs., *de*).

ASSOCIATION OF ENGINEERING SOCIETIES

Journal, vol. 55, no. 2/406, September 1915, St. Louis, Mo.

Asphaltic and Bitulithic Pavements:

Cost of Raw Materials and Cost of Mixing, R. S. Dulin
Cost of Grading, Hauling, Spreading, Rolling, etc.,
R. G. McMullen (both abstracted)

ASPHALTIC AND BITULITHIC PAVEMENTS: COST OF RAW MATERIALS AND COST OF MIXING, R. S. Dulin.

The paper presents cost data covering the items of raw material and mixing of asphaltic and bitulithic pavements.

ASPHALTIC AND BITULITHIC PAVEMENTS: COST OF GRADING, HAULING, SPREADING, ROLLING, ETC., R. G. McMullen.

This paper, which has to be read in connection with the preceding one, covers the cost items of grading, making the road, hauling, scarifying, shaping, spreading, rolling, etc.

The cost of hauling is based on the ton basis, using auto trucks of five ton capacity (the cost of maintenance and operation of the trucks is given in detail). The writer states that a table of all detailed costs in cubic yards and square yards for the different Multnomah County roads has been drawn up and a copy has been filed with the Board of County Commissioners, so that it is now a public record and open to inspection; in the article, this table is not reproduced.

The total cost of laying a 6 in. concrete pavement has been found to be \$1.05 per sq. yd. and the efficiency with which the building of concrete roads is now performed may be judged from the fact that of the total cost of the paving 70 per cent is the cost of materials, leaving 30 per cent, or a little over 30 cents per sq. yd. for the entire cost of labor, hauling of materials and the use of mechanical equipment on the job. In other words, the cost of raw material was \$0.74, the cost of labor, \$0.31, making a total of \$1.05.

Ordinarily, the concrete pavement is 6 in. thick, while bituminous pavements are 2 in. thick, and the materials in the bituminous pavements are not so expensive as they are

TABLE 3 SUMMARY COST OF DATA FOR PAVEMENTS.

Hassam Class "A" . . .	105	0 709

taken from data collected by the engineers of the city of Portland, Oregon. The unit prices used for the various ingredients in the pavement mixtures have been taken as the same for the same materials, no matter in which pavement they were used.

For various types of pavements, the author indicates the limiting proportions of the various ingredients and materials required by the specifications, as well as the mean of the various proportions actually used in the samples tested, and explains how the samples were taken. Table 3 gives a summary of the cost data for various pavements. This Table has been so arranged that pavements which are naturally competitive are placed consecutively. The comparative cost of the materials, for wearing surface, binder, base and entire pavement, are given for twelve different types of pavements (9 pp., *p*).

in the concrete pavement. The writer contends, therefore, that a 2 in. bituminous pavement can be laid for \$0.60 per sq. yd., including overhead charges, etc., or an actual cost of \$0.532. It must be remembered, however, that the above figures are not what the contractor's cost would be, but only the actual cost of laying the pavement and the question of "profits" (and also the cost of capital, etc., which the contractors have to take into consideration) has not been considered here.

Some of the speakers objected to the above figures as being too low, and pointed out several items which have been omitted, such as liability insurance, repairs to the plant, bond premiums, depreciation of the automobile trucks used in hauling materials, office expenses, plant site preparation, fire insurance, etc. As one of the speakers tersely stated, "for a contractor to omit any of these items would be fatal

and it would amount to just the difference between being able to accomplish a good job and break even, and getting in the hole and losing considerable money." (16 pp., p.)

BRITISH ASSOCIATION, MANCHESTER MEETING, SECTION G.

TESTING TOOL STEELS, Professor A. B. Field.

The paper reports some data of an investigation of tool steels and cutting tools.

One of the first points to be determined was the degree of uniformity obtainable in the heat treatment of special tool steels, so that the results could be duplicated at will, and successive tools used for comparative operations could be depended upon to be uniformly similar. In this connection the dynamometer arrangement constructed by the late Doctor J. T. Nicholson, of the Manchester School of Technology, is of great interest. The forces exerted on the tip of the tool by the material being cut in ordinary heavy engineering work might easily exceed 10 tons, and it is necessary not only to measure forces of this order, but to do so without giving the tool sufficient freedom of motion to affect the cutting operation of the lathe. The first dynamometer made measured the most important component of the force, viz., that in the direction of the motion of the work relatively to the tool. The dynamometer which was used later measured the components of force in three directions at right angles to one another, and thus completely determined the resultant force on the tip of the tool, except that the exact point of application had necessarily to be estimated. That the tool could be given the necessary freedom for determining these three forces while it was making a cut in steel to a depth of $\frac{3}{8}$ in. at a rate of feed of $\frac{1}{8}$ in., with some six tons force on its tip, without impairing the normal operation of the cutting, may be considered a triumph.

More recently, a device has been constructed in the shops of the Manchester School of Technology for determining a corresponding system of forces which arises in the operation of a milling cutter. In this case, the forces exerted upon the work in both the tangential and radial directions were measured on a dynamometer, diagrammatic provision being made for a possible negative force and the axial force being measured on the milling spindle itself. In the laboratory of the same institution, a comparatively rapid method has been developed for determining the ultimate endurance to rapid reversals in the material by a short series of direct reversal tests upon each of half a dozen or so specimens of the material.

As the Proceedings of the British Association containing the above paper are not available, this abstract has been made from a report in *Page's Engineering Weekly*, vol. 27, no. 577, October 1, 1915.

INSTITUTION OF MECHANICAL ENGINEERS

Journal, no. 7, October 1915, London.

The Theory of Grinding, with Reference to the Selection of Speeds in Plain and Internal Work (abstract)
Struts and Tie-Rods in Motion, H. Mawson (abstracted)

THE THEORY OF GRINDING, WITH REFERENCE TO THE SELECTION OF SPEEDS IN PLAIN AND INTERNAL WORK, James J. Guest.

The question of the best work surface-speed in grinding

is one which is constantly being raised, and there is a universally accepted belief that it should have some definite value dependent not only on the abrasive, grit, and grade of the wheel, but on the material of the work. Opinions and practice vary widely as to what this value should be, and for many years the values used have steadily lessened.

In the paper, the author puts forward his theory of grinding, which is based rationally upon a consideration of the action taking place between the wheel and the work and of the power involved. The conclusion first reached is that the quantity which the author terms the normal material velocity must lie between certain limits. In cylindrical work

the value of the normal material velocity is $\sqrt{2v^2 \frac{d+D}{dD}}$

where d and D are the diameters of the work and the wheel respectively, v the work surface-velocity, and t the depth of the cut; the positive sign is to be taken for external and the negative for internal grinding. If this quantity exceeds a certain value which depends on the grit and grade of the wheel and on the material of the work, the wheel will wear away too rapidly; while if it be less than a certain other quantity, the wheel will glaze.

The fact that a machine is designed to take up to a certain amount of power, limits the value of vt for any particular grade of wheel; if vt has any less value than this, the machine is not utilizing the full power supply. By considering these two controlling factors in combination, the methods of efficient grinding are deduced. The best work surface-speed thus depends not only upon the material of the wheel and of the work, but also upon their diameters and the particular machine in use, and the current belief that it should have a fixed invariable value is shown to be fallacious.

The case of a piece of work already on the machine and causing trouble in the grinding is first considered. If the wheel is wearing too rapidly, it is natural to reduce the cross-feed to check it, a course which is efficacious but of bad economy. It has been discovered by experience that it is better to reduce the work-speed until the wheel wears well enough. The author, however, shows that the correct course is to reduce the work-speed much further and to increase the cross-feed simultaneously.

When, on any particular machine, work of various diameters is handled, or wheels of different diameters are used, the best work surface-speed is shown to be proportional to

$\frac{dD}{d \pm D}$. By taking numerical examples of plain (external)

grinding, it is found that work of small diameter should run at a slower surface-speed than is suitable for work of larger diameter; considerations of vibration and chatter, however, frequently render it necessary to use less force upon slender work, and this leads to an increase of this natural surface speed. With work of large diameter, the formula leads to high surface-speeds combined with fine cross-feeds; the difficulty of using fine cross-feeds renders this undesirable, and it is proved that the way to overcome this trouble is to reduce the width of the wheel, which permits slower work surface-speeds and heavier cuts to be used.

The effect of wheel size and wear is then taken up; it is of little importance in plain (external) work, but lies at the root of the principal trouble in internal grinding, as it causes the

regime of the grinding to alter continuously. To secure the best output, the work-speed should be proportional to $\frac{dD}{d-D}$ in internal grinding, and the natural work-speed very high when the work is only a little less than the hole. The corresponding cross-feed will be small—so much so as to be unworkable, unless more power is used per inch of wheel-face than is the practice in external grinding. If the width of the wheel be selected so that the grinding can just take place, the wheel-face will be on the point of glazing. As it wears down in size, it at first works better, but afterwards commences to waste away. The work-speed should then be lowered and the depth of cut increased, which will alter the action so that the wheel again works well or tends to glaze according to the amount of the alteration.

The area of contact, which is commonly supposed to be the important factor in internal grinding, has no direct effect. The area of contact, however, is shown to be a measure of the rate of removal of material, and in internal grinding a narrow wheel and a long arc of contact are necessary.

Change of wheel grade has a double effect. For a softer wheel, a smaller normal material velocity must be used, and at the same time the value of vt increased for any particular machine. This leads to lower work surface-speeds and heavier cross-feeds. Combined with the increase of power per unit width of wheel-face, adopted in modern machinery with the view of increasing output, the result during recent years has been the continuous lowering of the work-speeds used.

The theory has been treated somewhat discursively in the author's book on grinding machinery, but in this paper it is presented logically and stripped of all adventitious matter; only the needful properties of the wheel are involved so that the application may be as broad as possible.

STRUTS AND TIE-RODS IN MOTION, H. MAWSON

The author shows how the stresses in a rod which is in motion and subjected to an endlong force, may be calculated; he shows further that the formulæ which have been derived for forces in stationary struts are only special cases of those obtained for rods in motion.

He takes first the case of a uniform circular shaft of a certain weight per unit of length, rotating at a speed (in radians per second) in bearings which do not constrain it in any way and assumes that it is subjected to an endlong compressive force. He derives an equation which shows that as the speed increases, the critical endlong force rapidly diminishes and that if the speed be zero, then we have a stationary strut, loaded with a certain weight per unit of length and the critical endlong force is found to be Euler's load. The same equation gives an expression for the critical speed of the shaft, which is found to decrease as the endlong compressive force increases. Moreover, when this force is zero, the equation gives an expression for the whirling speed of a shaft rotating in bearings and not subjected to any endlong force.

The author considers next the case of a rotating shaft subjected to an endlong tensile force F and derives an equation which gives an expression for the speed in radians and the endlong tensile force F , also showing that the greater the value of F , the greater the angular velocity has to be before whirling takes place; hence, the whirling might be

prevented by applying an endlong tensile force to the rotating shaft.

Next the author takes the case of a uniform rod, every portion of which describes a vertical circle and is subjected to an endlong compressive force S . He discusses the three possible cases covering the relation between the position of the rod, weight and centrifugal force, and derives certain equations which, among other things, prove that a circular rod, rotating as a coupling rod and subjected to an endlong compressive force, will whirl at the same angular velocity as it would if rotating as a shaft and subjected to the same endlong force, no matter what the radius of the vertical circle may be, since the moment of inertia about all axes of bending is constant.

The same equation for the maximum stress has been applied to a particular locomotive coupling rod, which broke while in service, and the results are tabulated in Table 0. The particulars and dimensions relating to this rod (1-section) are as follows: Diameter of cylinder, 18 in.; working steam-pressure, 160 lb. per sq. in.; radius at which rod acts, 12 in.; distance between centers, 8 ft. 11 in.; diameter of wheels to which rod was attached, 6 ft. mean sectional area, 6.53 sq. in.; mean moment of inertia I , about the axes of bending, 12.5 in.⁴ units; mean weight per inch run, 1.85 lb. Calculations have been made for steam pressures of 160 and 200 lb. per sq. in. at different speeds of the engine, the direct stress $\frac{F}{A}$ being taken as the full steam pressure on the piston divided by the sectional area of the coupling rod.

It will be noticed that the stress increases very rapidly as the speed of the engine increases, and that at the high speeds an increase in steam pressure does not appear to have as disastrous an effect as an increase in speed. It is also seen that at 60 miles per hour, with the ordinary working pressure of 160 lb. per sq. in., the stress in the rod is 9.82 tons per sq. in., which is rather high considering that the stresses are of an alternating character, first compressive and then tensile. Should the wheels slip upon the rail, it is quite possible that they may revolve at a speed equivalent to 80 or more miles per hour, and the stresses may then exceed the elastic limit. The rods have been known to break in cases of derailment owing to the high speed with which they rotate in such cases.

The author cites the formulæ for stresses in uniformly loaded coupling rods given by Professor Perry and Professor Unwin, and shows that while the results obtained by applying the Perry formula agreed very closely with the determinations obtained from the author's equation, the results from the Unwin formula give stresses considerably below them.

Since the derivation of stresses from the equation given by the author is laborious, he suggests another method which gives results in very close agreement with those derived from the equation above referred to. Considering the coupling rod to

be subjected to a uniform load of $w_1 = w + \frac{w''}{g} a^2 r$ lb. per unit run, where w is the weight of unit length of the rod, the bending moment due to this = $\frac{w_1 l^2}{8}$

The stress due to this bending moment = $\frac{w_1 l^2}{8Z} = f_m$

The deflection at the center due to this uniform load is

$$\frac{5}{384} \frac{w_1 l^4}{EI} = \delta$$

The stress due to the pressure F acting at a distance δ from

$$\text{the axis} = \frac{F\delta}{Z} = f_a$$

$$\text{The direct stress} = \frac{F}{A} = f$$

$$\text{Total stress} = f + f_a + f_a$$

Treating the rod in this manner, the results of Table 4 have been obtained for different speeds of the engine with the steam pressure at 160 and 200 lb. per sq. in. (11 pp., 3 figs., *tm*).

TABLE 4 STRESSES IN A COUPLING-ROD AS A FUNCTION OF SPEED OF ENGINE AND STEAM PRESSURE

Speed of Engine in miles per hour	Steam Pressure 160 lb. per sq. in.	Steam Pressure 200 lb. per sq. in.
	Stress in Rod Tons per sq. in.	Stress in Rod Tons per sq. in.
10	3.2	3.95
20	3.78	4.60
30	4.70	5.25
40	6.18	6.8
50	7.70	8.7
60	9.82	10.8
70	12.30	13.3
80	15.2	16.4

SCIENTIFIC SOCIETY OF THE ROYAL TECHNICAL COL-
LEGE, GLASGOW

SAFETY VALVES, D. MacNicol.

As the original publications of the Society are not avail-
able, the abstract is taken from the reprint of the paper in
the *Mechanical World* (London, vol. 58, nos. 1497 and 1499,
September 10 and 24, 1915). The date of reading of the
paper is not given.

With the advent of oil fuel in the British Navy, determina-
tions of the sizes of safety valves based on a formula using
coal as a factor, proved altogether inadequate. (The formu-
la for the sizes of safety valves in the Board of Trade
rules is derived from the area of fire grate and steam pres-
sure and with the Admiralty, from the heating surface and
steam pressure.)

The first oil fuel vessel in which trouble was experienced
was H. M. S. *Cossack*, a torpedo boat destroyer. During the
accumulation trial, the steam pressure rose to a dangerous
extent with the pointer of the gage going up rapidly; to
prevent an accident, the easing gear was applied. It was
observed that it required only a very small additional lift to
the valves, somewhere about $\frac{1}{4}$ in., to keep the accumulation
pressure below the danger point, and that the pressure in
discharge steam was excessive. These valves were quad-
ruple, 3.625 in. diameter, with a discharge pipe of 7.25 in.
bore. New valves were then fitted, also quadruple, but 3.75
in. in diameter, with two discharge pipes, each of 7.25 in.
bore. This was found satisfactory.

Meanwhile Mr. Gibson, of Cammell, Laird & Company,
carried out a series of interesting experiments on one of the

original valves. A small steam cylinder, fitted with a pis-
ton, was mounted on the boiler shell in the vicinity of the
safety valve and the piston attached to the easing gear in
such a manner that when the piston moved upwards, the
valve was eased. The bottom of the cylinder was connected
with the discharge steam space of the safety valve, and the
effect was that excessive pressure in the discharge steam
space assisted the valve to lift instead of preventing it from
doing so. Fig. 4A shows this arrangement. The trials were
most satisfactory.

About the same time, another torpedo boat destroyer,
H. M. S. *Swift*, was equipped with quadruple 3.375 in.

FIG. 4 SAFETY VALVES FOR OIL FIRED BOILERS (MARINE)

valves; but instead of having an external cylinder, each
valve was fitted with a balancing piston or disc, which neu-
tralized the effect of back pressure, (Fig. B). It proved
entirely satisfactory, so far as the accumulation allowance
was concerned, and it also proved that the size of the safety
valve was sufficient, but that a much larger waste steam pipe
would have to be used if no balancing arrangement was
adopted. In consequence of the experience gained, the firm
of Cockburns, of Cardonald, decided that in the future, for
the Admiralty type of safety valve, they would determine
the size of valves from the evaporation expected under ac-
cumulation conditions, and from that, the discharge pipe

area should be based on passing the evaporation at a pressure not exceeding 15 lb. pipe gage, or 30 lb. per sq. in. absolute. A large number of valves were constructed under these conditions with perfectly satisfactory results.

SOCIETY OF ENGINEERS

Vol. 6, nos. 8 and 9, August and September 1915, London
THE UTILIZATION OF SOLAR ENERGY, A. S. E. Aekermann

Discussion of the problem of utilization of solar energy as a source of motive power. A brief history of former efforts is given, among other things, the Willsie experiments at Pasadena, California, at Hardyville, Arizona, and St. Louis, Missouri. Four appendixes are given. Appendix 1 refers to the Shuman-Boys absorber in Egypt; in Appendix 2 the author derives the following equation of the theoretical efficiency of a solar heat absorber:

$$\eta = \frac{Dsa - pk(T^4 - \frac{2}{3}A^4) - (1-r)Dsa}{Dsa}$$

where D is the width of the reflector in feet; p , the perimeter of the boiler in feet; r , the efficiency of silvered glass as a

the maximum thermal efficiency of the absorber alone. The equation for the over-all efficiency of the plant is

$$\eta_o = \frac{[Dsa - pk(T^4 - \frac{2}{3}A^4) - (1-r)Dsa]}{Dsa T} (T - 568)$$

where T is the absolute temperature of the steam and 568 the absolute temperature of the condenser in deg. fahr. (taken as constant), the other symbols having the same meanings as in the equation given in Appendix 2. Assuming the mirrors to have a temperature of 100 deg. fahr. and inserting the values of the other quantities (except T), the equation becomes:

$$\eta_o = 0.71 - 404 T^{-1} + 9.45 \times 10^{-10} T^3 - 1.664 \times 10^{-12} T^4$$

Differentiating this equation with regard to T , and equating the result to zero, the value of T is obtained, which gives the maximum over-all efficiency under the given conditions.

This being done, it is found that $T = (231 - 461)$ deg. fahr., corresponding to a steam pressure of 21 lb. sq. in. abs. Inserting this value of T in the equation just given, the theoretical maximum over-all efficiency of the Meadi absorber, combined with a Carnot engine, is found to be 5.9 per cent., while the actual maximum was 4.32 per cent. The relative efficiency was thus 73.2 per cent. This means that nearly three-quarters of the boiler horse power theoretically possible under the stated conditions was obtained.

Instead of differentiating the equation to η , it is possible to insert various values of T , and thus calculate the corresponding values of η_o and plot the results. The value of T which gives the maximum commercial economy is then readily seen in the inspection to be 231 deg. fahr. as before, (Fig. 5). It is also seen that $\eta_o = 0$ when $T = 568$ deg. fahr. (= T_c , the temperature of the condenser), or when $T = 809$ deg. fahr. The latter corresponds with a steam pressure of 131 lb. sq. in. abs., and means that the loss by radiation and conduction from the boilers and by the inefficiency of the mirrors would then be equal to the solar heat received.

Appendix 4 is a bibliography of the subject.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as c comparative; d descriptive; e experimental; g general; h historical; m mathematical; p practical; s statistical; t theoretical. Articles of especial merit are rated A by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles in the Survey.

FIG. 5 CURVE SHOWING THE RELATION OF THE OVER-ALL EFFICIENCY OF THE 1913 SHUMAN-BOYS SUN-HEAT ABSORBER (WITH NAKED BOILER) COMBINED WITH A CARNOT ENGINE, TO THE ABSOLUTE TEMPERATURE OF THE BOILER STEAM

reflector of heat; s , the solar constant in B.T.U. per square foot per minute = 7.12; a , the coefficient of atmospheric transmission; T , absolute temperature of the boiler in deg. fahr.; A , absolute temperature of the reflectors in deg. fahr. The temperature A was found to be about 9 deg. fahr. above the shade temperature of atmosphere. The efficiencies thus calculated were compared with those obtained by experiment, and were shown to be rather higher.

In Appendix 3, the author demonstrated that the best commercial result on over-all efficiency obtained from a solar heat absorber and engine did not necessarily correspond with

MEETINGS

MILWAUKEE, SEPTEMBER 1915

About 150 members and guests attended the opening meeting of the Milwaukee Section in September. Col. Henry A. Allen, Mem. Am. Soc. M. E. and consulting engineer for the City of Chicago, gave a very interesting, illustrated talk on Municipal Waste, describing very fully the development and present status of the garbage and ash handling in Chicago. He also gave a short talk on the Eastland disaster and dwelt quite fully on the stability of vessels. Col. Allen closed his talk with a description of the new Winslow high pressure steam boiler.

PROVIDENCE, SEPTEMBER 22

The opening meeting of the Providence Association of Mechanical Engineers was held in Engineering Building, Brown University, on Wednesday evening, September 22, at which F. H. Small presented a paper on the Manufacture of Leather Belting. Mr. Small has had a wide experience in this line and presented to the meeting an unusually interesting account of the various processes involved from the curing of the leather hides down to the selection of the proper size of a belt for any particular condition of driving. During the latter part of his address, he devoted considerable attention to many of the important but too little understood features of the proper application of leather belting in power transmission; he showed that, where oftentimes a belt drive has proved unsatisfactory, a very slight change in the width or thickness of a belt will correct the fault and give the belt a very greatly increased life.

CINCINNATI, SEPTEMBER 30

A joint meeting of the Cincinnati Section of The American Society of Mechanical Engineers and the Engineers' Club of Cincinnati was held on the evening of September 30. John S. Crandell, formerly of the Highway Engineering Department of the Pennsylvania State College, spoke on Coal Tar Products and Road Building. The speaker began by carefully defining such terms as tar, bitumen, and asphalt. He discussed at some length the tar derivatives and the characteristics of coal-gas tar, water-gas tar, coke-oven tar and the characteristics of the various oils and pitches obtained from different coals, and from the same coals by varying the process. Retorts for distillation were illustrated by lantern slides. Some of the fundamental principles of road building were discussed by the speaker and the use of tar products in the top dressings of roads was elaborated in some detail. Various methods of forming the surfaces and distributing the pitch were illustrated by moving pictures. The paper was one of great interest and provoked considerable discussion.

The president of the Engineers' Club, who represented the club at a recent meeting of the Dixie Highway Commissioners at Chattanooga, gave a brief report of that meeting and showed on a map the various routes that had been decided upon, including the one through Cincinnati. About 75 members and guests were present.

NEW YORK, OCTOBER 12

The opening meeting of the New York local section was held on October 12, when a paper by Frank B. Gilbreth, Mem. Am. Soc. M. E., on Motion Study for Crippled Soldiers was presented by Robert T. Kent, Mem. Am. Soc.

M. E. Edward Van Winkle, chairman of the section, presided at the meeting.

In carrying out his development of scientific management in industrial plants and hospitals, Mr. Gilbreth has recently spent several months in Germany, and while there he became much impressed with the great problem which will confront the world of training the millions of soldiers crippled by the war to resume their places in industrial life and become self-supporting. He has been asked to put the results of modern management in general, and motion study in particular, at the disposal of those in active charge of training the cripples.

The first step in adequate placement of men through motion study lies in visualizing the motions used, or necessary, in any given type of work. This is done by means of the simultaneous cycle motion charts, devised and used by Mr. Gilbreth, which record the inter-relation of the individual motions and cycles of motions used in any method of performing any piece of work. By analysis, he is able to work out from the charts new methods of doing a piece of work. Thus many types of work formerly considered possible only for the man in complete possession of all his members and faculties can be adapted to the maimed or crippled worker.

The data included in these charts are gathered through various methods of making motion studies. From these records are made motion models that make it possible for teacher and learner to visualize the desired motions.

By means of these methods, the selected elements of skill and experience can be transferred in a new syntheticized cycle of least waste, to crippled learners where it is often necessary to specialize on some particular sense training.

While this method of study is bringing in gratifying results, no great headway can be made with the crippled soldiers' problem without worldwide coöperation. Such coöperation has been forthcoming wherever interest has been aroused, but Mr. Gilbreth begs for more. He needs photographs, records, and histories of cases where cripples have been taught successfully to do work and he also needs suggestions for adaptations of machines, tools, and other equipment or surroundings to workers.

MILWAUKEE, OCTOBER 13

At a meeting of the Engineers Society of Milwaukee on October 13, H. J. Manger delivered a very interesting talk on the Electric Heating Industry. The local electric light company sent over a rather complete line of heating and cooking apparatus, and several of the company's demonstrators were present who baked some cookies and broiled some steak. Mr. Manger said that the local company has just adopted a rate of 2 cents per kw-hr. for cooking. He said that this would cost the average family from \$2.00 to \$3.00 per month for electric cooking.

BUFFALO, OCTOBER 13

On October 13, a joint meeting under the auspices of the American Institute of Electrical Engineers was held in Boston, following out a new scheme of coöperation among the Civil Engineers, the Electrical Engineers and the Mechanical Engineers. The subject was Load Dispatching as Handled by Large Electrical Power Distributors. Mr. P. Kent of the Boston Edison Company and Mr. Masters of the Boston Elevated Company presented papers and lantern slides. J. M. Cushing of the Electrical Engineers explained

the scheme of cooperation among the engineering societies. The guest of the evening was J. J. Carty, president of the American Institute of Electrical Engineers, who spoke on the value of engineering societies to its members.

BUFFALO, OCTOBER 20

On Wednesday evening, October 20, the Engineering Society of Buffalo held its first meeting at the Hotel Statler. A dinner was served at which about 150 members participated. After the dinner, W. B. Hunter, director of the Fitchburg (Mass.) High School, gave an address on The Training of Mechanics, laying special emphasis on the work that has been done with the Fitchburg cooperative system. This system consists in having relays of students, one relay in the High School, while the second relay is working in the shops. The succeeding week the two sets of students change places. This system is working out very successfully and there is no question that it is a step forward towards the solution of the problem of getting mechanics.

There was a discussion following the address. Over 200 members were present at this meeting.

MINNESOTA, OCTOBER 21

The regular meeting of the Minnesota Section was held at the University of Minnesota on October 21 at which Quincy A. Hall, Mem. Am. Soc. M. E., presented a paper on the History of the Panama Canal. This paper covered the time from the first activities of the French down to the present time. Mr. Hall was well qualified to handle the subject as he has spent six years in the Canal Zone as a testing engineer.

NECROLOGY

JOHN PARKER

John Parker was born in Mansfield, England, on March 28, 1864, and came to this country in 1887. For four years, he was employed in the drafting department of the Corliss Steam Engine Company in Providence, R. I., and in 1891, he accepted a position with the Brown and Sharpe Manufacturing Company. In 1893, he took active charge of their miller designing and in connection with this position also held that of assistant chief draftsman, 1895-1902. As assistant chief draftsman he developed executive ability in putting work through correctly and efficiently, and many patents were granted to him chiefly in connection with his work on millers. He was in charge of the miller designing for this company up to the time of his death, which occurred on July 23, 1915. He became a member of the Society in 1909.

JAMES P. TOLMAN

James P. Tolman was born in Boston, Mass., on November 7, 1847. He received his early education in the public schools of Boston and entered the Massachusetts Institute of Technology, from which he took the degree of Mining Engineer in 1868, which was the first class to be graduated from the Institute. In 1870, he became superintendent of the Silver Lake Cordage Company of Newtonville, Mass. He then organized the J. P. Tolman & Company in 1884 which manufactured braided cord. In 1888, the Samson Cordage Company in Shirley, Mass., was organized as successors of the J. P. Tolman Company and Mr. Tolman became president of the company, which position he held up

to the time of his death. This company is one of the largest in the world manufacturing braided cord. Mr. Tolman became a member of the Society in 1894. He died at his home in West Newton, Mass., on July 28, 1915.

ARTHUR S. MANN

Arthur S. Mann was born in West Medway, Mass., on September 4, 1867. He received his early education in the schools of Medway and graduated from the Massachusetts Institute of Technology with the degree of S.B. in 1888. The first two years out of college were spent with the George F. Blake Manufacturing Company. Following this he was with the West End St. Railway Company in Boston, Mass. From 1892-1894, he was with the E. P. Allis Company of Milwaukee as mechanical engineer. In 1894, he started a machine shop with F. E. Lammert in Chicago, building special machinery and conducting a general engine repair trade. He was vice-president of this company up to the time of his death, although he had taken no active part in the business since 1897.

In 1897, he became engineer of construction of the Ninety-sixth Street power plant and operating chief engineer of the various plants for the Metropolitan Street Railway Company of New York City. In 1901, he accepted a position with the Sydney St. Railway Company in Australia as construction engineer of power plants. In 1903, he went with the General Electric Company in Schenectady, N. Y., where he was engineer in charge of construction of their power plants and of the steam, air and water distribution of their entire works. Also he was at the head of the installation of the new powdered coal system and had charge of the design of their new furnaces and boilers.

Mr. Mann became a member of the Society in 1900. He died on June 3, 1915.

PERSONALS

William I. Ballentine has resigned his position as general superintendent of the Link Belt Company's Indianapolis plants.

J. Ralph Belgiano has severed his connection with the Taylor-Wharton Iron and Steel Company of High Bridge, N. J., and is now associated as an engineer with The Emerson Company of New York, efficiency engineers. He has been assigned to work in the Chillicothe, Ohio, works of the B. & O. S. W. R. R.

Frank L. Dalas has accepted a position with the Youngstown Sheet and Tube Company of Youngstown, Ohio, in the electrical and mechanical department for the new extension of the plant.

Frank H. Schubart, until recently connected with the engineering department of Wheeler Condenser and Engineering Company, Carteret, N. J., has been appointed district manager of the St. Louis territory of the Company.

Alfred E. Ballin has become associated with the McIntosh and Seymour Corporation, Auburn, N. Y., as general manager. He was formerly manager of the gas and oil engine department of the Snow Steam Pump Works, Buffalo, N. Y.

Thomas W. Harris, Jr., recently connected with the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., as assistant to the works steam engineer, has accepted a position with E. I. du Pont de Nemours and Company, Wilmington, Del., as assistant in the purchasing department.

Jeann M. Allen has become associated with the Floesch Con-

struction Company, Inc., Cape Girardeau, Mo., as manager and engineer.

Percy C. Smith has resigned his position as sales manager and mechanical engineer for the Roto Company, Hartford, Conn., to accept the position of factory manager for the Maxim Silencer Company, Hartford, Conn.

STUDENT BRANCHES

CARNEGIE INSTITUTE OF TECHNOLOGY

The annual banquet and final meeting of the Carnegie Institute of Technology Student Branch was held on June 4, 1915. The following officers were elected: Benjamin Schwartz, president; L. W. Sherwood, vice-president; J. T. Eaton, secretary, and J. M. Guter, treasurer.

The business meeting was followed by a paper on Heat Transmission into Steam Boilers, by Henry Kreisinger of the United States Bureau of Mines. Mr. Kreisinger has been engaged in experimental work of this nature in the government laboratories for several years and is the author of a well known text book on the subject of boiler practice. Mr. Kreisinger opened his address by differentiating between the ordinary conception of a steam boiler as including the furnace, stack, etc., and the boiler as a steam generating unit, in which reference he treated it. He defined the problem of heat transmission as that of getting the heat from the gaseous products of combustion and the residue in the fuel bed, and into the boiler.

Mr. Kreisinger traced the path of the heat from the fire-box through the intervening space, a layer of soot, the boiler plate itself, a layer of mud and scale and a layer of steam to the water itself. He went into detail concerning radiation, absorption, conduction and convection in this connection. His investigations have shown that the path of the heat from the fire to the boiler surface is the slowest. A chart made from the direct results of an experiment showed how the temperature drop in this part of the heat path is enormous in comparison with the other parts. The results also showed a drop of 2150 deg. Fahr. from the fire to the boiler surface, a drop of 40 deg. through the metal tube, and a drop of 15 deg. through the layer of mud, scale and steam on the inside.

The next consideration was given to the possibility of increasing the rate of heat transmission into boilers and thereby increasing the capacity of given units. Three possibilities presented themselves: Increased initial temperature, increased density of the furnace gases and increased velocity of the furnace gases. The idea of increasing the density was given up because it opposed high initial temperature. Limits were assigned to the initial temperature and gas velocity because these conditions when extremely high are accompanied by great losses in the efficiency of the fuel.

A considerable part of the paper was given up to a description of the apparatus used in performing the experiments that led to these conclusions. The temperatures were measured by means of platinum, platinum-rhodium thermocouples. Those used inside the boiler were imbedded in the tube, and the one used for taking temperatures at different points in the flue was mounted on an eccentric at the end of the long rod. Every precaution was taken to avoid error and the known inaccuracies were taken into account in calculating the results.

Mr. Kreisinger defined true boiler efficiency as the ratio of the heat absorbed by the boiler divided by the heat available for absorption. The heat available for absorption being the part of the heat in the hot gases which is above the temperature of steam. He then showed how more rapid transmission into the boiler will increase the amount of heat that is absorbed and thereby increase the efficiency of the boiler.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College on October 12, the following papers were presented: The Value of Public Speaking to the Engineer, by Professor Emerson

of the Public Speaking Department of the College; A Brief History of the A.S.M.E., by Dean A. A. Potter, Dean of the Engineering Division of the College, and The International Harvester Company's Gas Engine and Cream Separator Factory at Milwaukee, by Prof. W. W. Carlson, Professor of Shop Practice of the College. Professor Carlson described the route that the pig iron takes in the factory to the finished product and told of the many time saving devices which that company uses.

PENNSYLVANIA STATE COLLEGE

The first meeting of the year of the Pennsylvania State College Student Branch was held on September 30, at which Professors Moyer and Mease gave talks on the object of the A.S.M.E. and benefits which could be derived from it. They together with Professors Diemer, Wood and Bates urged the students to keep in touch with the Society by subscribing to The Journal and requested that as many of the senior students as possible try for the Junior Prize which has been offered by the Society. Dean R. L. Sackett, the newly appointed head of the Engineering School, told of his desire to further the interest in the Student Branch and said that he would do all that he could to cooperate with it.

POLYTECHNIC INSTITUTE OF BROOKLYN

At the first meeting of the Student Branch of the Polytechnic Institute of Brooklyn, 30 new men were admitted to membership in the branch and Dr. M. C. Hilseng, consulting professor of the Institute, was made an honorary member.

H. A. Brandt, chairman of the Branch, presented a paper on the Manufacture of Shrapnel. He described the intricacies of their manufacture and carefully explained the complex and difficult processes. Prof. W. D. Ennis of the Mechanical Engineering Department related his summer experiences with dynamite which he used on his farm for clearing away rocks and shattering hard clay to permit better drainage and for digging a ditch.

PURDUE UNIVERSITY

The opening meeting of the Purdue University Student Branch was held on October 2. The meeting was attended by 126 students and faculty and 38 applications for membership were received. Dean Benjamin, Prof. G. A. Young, honorary member of the branch, Prof. L. V. Ludy of the Engineering Laboratories and Prof. L. W. Wallace addressed the students on the advantages to engineering students of becoming affiliated with a student section of the Society, and urged them to join. They also spoke of the many opportunities and importance of belonging to an engineering society and the relation of the student section to the Society.

At a meeting of the branch on October 16, W. F. Borgard addressed the meeting on Electric Starting and Lighting Devices for Automobiles. He explained the different systems in use on several of the most important cars. He laid stress on the generators used on starting devices and their faults from a repair-man's point of view, and said that the principal fault with them was the difficulty in getting the connection between the engine and the dynamo. Mr. Borgard also spoke on the care of storage batteries especially during the winter.

RENSSELAER POLYTECHNIC INSTITUTE

The first regular meeting of the Rensselaer Polytechnic Institute Student Branch was held on September 30, at which the following officers were elected: J. B. Lincoln, president; K. Keeter, vice-president; J. W. Hartman, secretary, and R. D. Culver, secretary.

Following the business meeting, Howard E. Stevens spoke on Diesel Engines. Mr. Stevens confined his remarks to the two types of engines manufactured by the McIntosh and Seymour Corporation of Auburn, N. Y.

UNIVERSITY OF COLORADO

At the first regular meeting of the University of Colorado Student Branch on September 30, Prof. John A. Hunter,

Mem. Am. Soc. M.E., gave a review of the Spring Meeting of the Society at Buffalo. He also gave personal impressions of the various sessions and inspection tours and expressed his opinion of the value to be received from attendance at such a meeting. Later, other members of the Mechanical Engineering Faculty gave talks on interesting engineering undertakings and material encountered during the summer months, and mentioned opportunities for vacation work and experience open to students.

UNIVERSITY OF NEBRASKA

A meeting of the University of Nebraska Student Branch was held on October 7. The following committees were chosen: On new members, H. C. Edwards, R. B. Saxon, L. L. Sharp and I. F. Smith; on Posters to Advertise the A.S.M.E., J. W. Galloway and D. E. Stokke; on A.S.M.E. Smoker, J. C. Baker, W. C. Chapin and C. S. Spaulding; on student programs for A.S.M.E., H. F. Holtz and R. B. Gillespie.

Professor Hoffman, head of the Department of Mechanical Engineering, spoke on the success of the engineer and told of the value of technical papers in keeping posted in modern engineering ideas. He advised that each man join some national society of engineers after getting out of school as well as taking an active part in student branches while in school. He also emphasized the value of The Journal.

WASHINGTON UNIVERSITY

The student branch of Washington University held its first meeting of the year on October 12. The newly elected officers, consisting of Prof. E. L. Ohle, honorary chairman, John J. Summersby, chairman, W. H. Kurtz, vice-chairman, Edmond Siroky, secretary, and H. C. Keyser, treasurer, took up their respective duties. It was decided that student members be required to give papers before the branch; and if necessary the subjects are to be assigned by the executive committee.

Charles Proetz, a student, gave a talk on Carburetors and Mixing Valves in which he treated the history and present day practice in the design of carburetors. Although dwelling chiefly on American practice, he showed how it differed from that in Europe. The talk was made very interesting by specimens which he dissembled to show their parts. The talk was followed by discussions by Professor Ohle and Messrs. Brady, Meinholz and Siegerst.

WORCESTER POLYTECHNIC INSTITUTE

The first meeting of the college year of the Worcester Polytechnic Institute occurred on October 1. Prof. Charles M. Allen spoke on Experiments with Gasoline. He illustrated his remarks by many simple experiments, some of which were very dramatic and which impressed the audience as being quite dangerous. By a combination of experiments, he illustrated in an easily understood way just those things which are likely to occur when gasoline, kerosene and alcohol are handled ignorantly. He also called attention to some of the serious cases resulting from its ignorant use as reported in the daily press, explaining the sequences which must have taken place to give the resulting explosions. One of the most interesting experiments was "the four-cycle engine." A covered tin pail was used for a cylinder. A hole near the bottom of the can held an ordinary spark plug and a hole in the cover was closed by a small tin box which served as a piston. An atomizer made an excellent carburetor, the mixture being introduced into the cylinder through a hole near the bottom. Mixtures of varying richness were sent into the cylinder and the effect was noticed when the spark was produced and the little tin box ascended. The lecture was concluded with a "fire eating" experiment in which the lecturer lighted his breath after inhaling a quantity of gasoline vapor through a cigar. It should be added that Professor Allen "washed his hands" of all responsibility for the safety of anyone who might try to repeat his experiments.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 15th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. Stamps should be enclosed for forwarding applications.

286 Experienced designer familiar with machines, tools and jigs or forgings and pressed metal work. Location New York State. Apply by letter.

287 Manufacturing concern in the East wants capable designers and draftsmen with experience in the mechanical design of steam turbines. Special inducement for a leading designer and for squad leaders; also for a man with designing experience on condensers. Apply by letter, stating age, education, experience, salary desired, etc.

290 Mechanical draftsman experienced in the charge of a drafting room, and thoroughly familiar from practical experience with designing, erecting and handling machinery for elevating and conveying material in factories, warehouses, mills, mines, quarries, sand and gravel plants; also gravel washing and screening machinery; a complete knowledge of mechanical power transmitting machinery, and its installation. Correspondence will be kept strictly confidential. Give experience, addressing Lock Box 3097, San Francisco, Cal.

306 Large shop in Nashville, Tenn., desires engineer who is particularly well trained in electrical matters; work for present, mainly survey of shops to determine what future equipment is needed both in the shops and power plant. Salary \$1200 to start.

307 Competent engineer to prepare estimates and cost sheets for manufacture of war munitions. Location New York.

308 Draftsman experienced in design, layout and construction of refrigerating and ice-making plants. Apply by letter, stating experience, salary expected, etc. Location Connecticut.

309 Appraisal engineers for series of plants devoted to various branches of industrial chemistry. It is desired to secure a force of engineers competent to take off quantities from the various plants, to verify the execution and to measure up the work in the buildings; fitness of the plant for its chemical purposes is not in question. Employment will last from two to three months; possibly subsequent employment for some members of the force on a more permanent basis.

314 Draftsman for wood factory building. Must be familiar with piping and belt drives. Apply by letter.

316 Superintendent or foreman competent to take charge of plant and experienced in every department required in the manufacture of rides. Apply by letter.

318 High grade designer of machine tools; preference for a man who has had from 15 to 20 years' experience and one who is a practical shop man as well as a capable designer. Location Rochester, N. Y.

319 Sales engineer on steam turbines, centrifugal pumps, steam engines, hoisting machinery, feed water heaters, steam separators, etc. Apply by letter; location Pittsburgh.

321 Qualified engineer to conduct organization work for Canadian concern making all classes of fencing materials; one prepared to consider short term engagement. Apply by letter.

322 Assistant factory superintendent, one experienced in pump work. Location New York.

324 Three or four competent men to act as foremen in manufacturing plant, in assembling of mechanical parts of munitions. Salary \$100 to \$125 a month. Location New Jersey.

325 Paper mill engineer; must have initiative and be competent to take charge of all work in the mechanical engineering of a large paper mill. Applications should be accompanied by a statement of age, qualifications, and salary expected. Location Eastern Massachusetts.

329 Several expert mechanical draftsmen in ordnance work department. Location Maryland.

331 Designer, thoroughly familiar with design of firearms, especially gun stocks. Location New York.

334 Wanted time study man, preferably one having technical school training, subsequent machine shop experience, time study and efficiency work. It is essential that time study man be an experienced machine tool operator who can demonstrate any standards set by operating the machine tool. State fully training and experience, present position and minimum salary to start with this company. Location Buffalo, N. Y.

335 Partner wanted. Electrical engineer with experience and clientele will join mechanical engineer who is likewise equipped. Middle West preferred. Capital furnished and required. P. O. Box 617, Chicago.

339 Technical graduate or practical man with experience in design of gas and oil fired furnaces; structural iron work, especially foundations for machines subjected to heat; and structural steel containers for bulky material, as coal hoppers, etc. Apply by letter. Location New York.

345 Massachusetts manufacturer of small electrical apparatus, in quantities, requires the services of an assistant purchasing engineer for the inspection of incoming materials; applicant must be thoroughly familiar with electrical, insulating and composition casting materials, with practical knowledge of metal working and similar machinery; state details under headings of age, nationality, education, practical experience, salary, when at liberty.

346 Young engineer on development and sales of alloy steels as used in manufacture of automobiles and kindred purposes. Location Pennsylvania.

MEN AVAILABLE

The published notices of "men available" are made up from members of the Society. Notices are not repeated in consecutive issues of the Bulletin. Names and records are kept on the office list three months, and at the end of such period if desired must be renewed.

K-304 Member, M.E. and E.E., age 35, with nineteen years' practical experience in bolt and nut manufacture, rolling mills and tube mills, and light and heavy forging. A-1 on design and plant development. At present superintendent of agricultural forge works. Location lake or coast city. Salary \$4000.

K-305 Young mechanical engineer with three years' experience desires position as assistant to refinery manager or superintendent of large petroleum company in vicinity of New York.

K-306 Member, technical graduate, age 36, experienced in design and construction of structural steel work, machine tools, shop layout and arrangement of machinery, efficiency management, accounting and costs, works management, planning and routing, orders and stores, and also with experience as sales engineer, desires to become associated with a shipbuilding concern or an allied industry. Prefers to locate in New York or Philadelphia.

K-307 Member, M.E., twenty years' varied practice in general engineering and capable of assuming responsibility and control, an experienced designer, and one who has traveled extensively, desires to get in touch with concern re-

quiring a reliable man in executive shop or office position. Salary \$3000.

K-308 Technical graduate, age 24, three years' experience, two in manufacture and design of hydraulic machinery, one in plant department of New York public service corporation, desires a position in the engineering department of manufacturing or operating company located in Middle West.

K-309 Technical graduate, wide experience as railway mechanical engineer, machinist, motive power draftsman and mechanical engineer, desires position along these lines, or one as mechanical inspector, assistant superintendent of motive power, or assistant to general manager. Location immaterial.

K-310 College man, both electrical and mechanical, with fourteen years' experience in engineer's office, textile and rubber factories and electric light company, desires position in engineering or mechanical department of some large industrial concern, with consulting engineer or electric lighting company.

K-311 Associate-member, age 34, with seven years' experience as designer, chief draftsman and assistant engineer in the automobile and gas engine line, and two years as designer of gasoline mine tractors and mining machinery in general, wishes position as chief draftsman or assistant engineer in concern manufacturing along these lines. Location preferred New York.

K-312 Member, graduate engineer, age 40, American, twenty years' experience as salesman and office manager for company making air moving machinery and power apparatus, well acquainted with manufacturing plants, engineers and architects in New York territory, wants sales representation for mechanical apparatus on salary, or salary and commission basis. Location New York.

K-313 Junior member, M.E., age 26, three and one half years' experience in railroad motive power and mechanical department work, desires position with railroad or locomotive manufacturer with chance for advancement. At present employed.

K-314 Member, technical graduate, with twelve years' experience and who has made tests on boilers, engines, stokers, etc., and who has advised on fuel and made plans and specifications for new work, desires position with private firm or consulting engineer to superintendent of production of power.

K-315 Mechanical engineer with several years' experience in pump business as designer and chief draftsman is open for position.

K-316 Graduate mechanical engineer, age 31, thoroughly experienced in modern publicity work as applied to products of a mechanical nature, is open for position as advertising manager. Replies are solicited only from high grade firms that believe in clean cut, dignified methods, and are willing to pay a suitable salary for capable service.

K-317 Sales engineer, district office manager or agent, technical graduate M.E., ten years' successful sales record handling power plant equipment and problems in power transmission, covering a wide field of industries, seeks similar position with greater opportunities. At present employed.

K-318 Member, who has had charge of some of the leading foundries of the country and is capable of handling any foundry proposition, desires position as general manager or superintendent of foundry.

K-319 Junior member, Columbia graduate M.E., 1913, two years' experience in production and drafting department, desires position in New York with chance for advancement. At present employed.

K-320 Mechanical, electrical and structural engineer desires position of responsibility with electric power company, engineering concern or railroad company with chance of advancement. At present employed as assistant engineer of construction on two 15,000 kw. stations.

K-321 Member, mechanical and electrical engineer, age 37, married, technical graduate, fifteen years' experience chiefly in design, construction, and operation of power plants, street railways and heavy machinery, would prefer position as master mechanic, superintendent or chief engineer.

K-322 Member, seventeen years' experience, with ability to determine the most economical method of manufacture, and to supervise the design and building of tools, punches, and dies, milling fixtures, jigs and screw machine tools, or other equipment such as special machinery, and one who can determine cutting speeds and feeds and piece work rates, also the installation, care and maintenance of the power plant and transmission, desires position as master mechanic where experience would be of value.

K-323 Member, age 35, with an unusually thorough experience in rubber mill engineering, including developments, reports, designs, specifications and contracts for buildings, power requirements and manufacturing equipment, desires position with consulting engineer or large rubber mill. Salary \$4000. At present employed.

K-324 Junior member, age 31, married, technical graduate in mechanical engineering, five years' experience in power plants, testing investigations, and general mill engineering, wishes position with progressive company as assistant works manager, mechanical engineer, or similar capacity. Would prefer to become associated with the automobile industry.

K-325 Member, with successful and satisfactory record and wide acquaintance among automobile and automobile parts manufacturers, now holding position as sales and advertising manager, desires similar position with company.

K-326 Member, fifteen years' experience as designing and executive engineer, has specialized in machine design, power economy and mill supervision, desires position. Specially qualified for paper mill work.

K-327 Member, technical graduate, age 30, ten years' experience in treating, testing and micro-structure of steel; practical knowledge of the treatment of steels to obtain best physical and machining properties; capable of eliminating all troubles in the working of steel and manufacture of steel products.

K-328 Member of the Society, technical education and shop experience, age 38, married, sixteen years' experience with two railroads and one locomotive manufacturer, designing and constructing locomotives, cars, automobiles, motor cars and special railway equipment, desires position with a railroad company.

K-329 Industrial engineer, analytical and creative ability of the highest order; excellent manager of help, experienced in textile, food and manufacturing plants, mine quarries and department stores.

K-330 Technical graduate, age 31, nine years' broad experience in designing, manufacturing and testing special machinery, also delicate instrument work, thoroughly familiar with drawing office methods, pattern, foundry and machine shop practice, good executive, can handle correspondence, and draw up specifications, desires a position. Location immaterial.

K-331 Member of the Society, eight years' practical experience in general mechanical engineering, and four years in the installation of scientific management, desires a position with a progressive concern as efficiency or production engineer.

K-332 Ordnance engineer, member, M.E. degree 1913, age 35, married, fourteen years' experience, five and one-

half years in army ordnance department, three and one-half years captain of coast artillery, completed ordnance school of application, familiar with electrical machinery and gas engines, commended for management and also familiar with efficiency systems, desires administrative position in development of military manufacture.

K-333 Member, age 33, Cornell graduate, twelve years' experience in machinery manufacture, design, sales, installation and operation, at present sales manager in Chicago for large machinery corporation, would consider proposition to fill responsible executive position. Location immaterial.

K-334 Junior member, technical graduate, twelve years' experience as chief engineer, designing, estimating, constructing and selling steam engines and boilers, steel, plate work, elevated tanks and towers, and general foundry and machine work, successful sales record, desires position. Immediate salary secondary to good opportunity for advancement.

K-335 Professor of mechanical engineering in a Canadian University, technical graduate of A-1 U. S. institution, both M.E. and E.E. training, has held responsible position in large manufacturing plant as well as important U. S. government post as engineering expert, also has had four and one-half years' successful teaching experience, and is author of engineering text books and numerous technical articles, desires teaching position in U. S. college.

K-336 Mechanical engineer, age 28, six years' experience, four years including foundry, machine shop, drafting and testing; two years power and mill machinery, installation and maintenance, wishes position.

K-337 Member, age 37, wide experience in factory engineering and power plant design, construction and operation, desires position as mechanical engineer or master mechanic.

K-338 Junior member, M.E., age 28, five years' experience in construction and equipping of manufacturing, supply or importing or exporting house. Familiar with far Eastern market.

K-339 Mechanical engineer, American, Junior, capable of taking charge of test floor, erection work, power plant investigation, technical correspondence, factory maintenance and purchasing. Energetic and reliable; can speak German. At present employed.

K-340 Mechanical engineer, member, age 40, married, twenty-five years' experience in the design of engines and water tube boilers, together with the plant and equipment for their manufacture, along the latest and most efficient lines, experienced also in the production of forgings, both drop and press work, desires administrative position in the development of the manufacture of all classes of forgings.

K-341 Member, technical education, twenty years' experience as general manager and treasurer of engineering works, also in charge of sales department, thorough practical experience and application of labor saving machinery in foundries and machine shops in various lines of general engineering work.

K-342 Young man, age 24, graduate of Lehigh University, has had two years' shop experience, desires position in engineering department of a manufacturing concern. Location immaterial.

K-343 Graduate of Worcester Polytechnic Institute, has had some experience in cost and efficiency work, interested in factory management and cost finding, would like position with manufacturing concern.

K-344 Member, age 32, technical graduate, solicits representation of a reputable firm, in Philadelphia, or would accept responsible position in a mechanical engineering capacity.

K-345 Associate-member, age 35, M.E., 1907, ten years' experience, five years in designing ordnance equipment and

machinery at the United States Naval Gun Factory, Washington, D. C.; five years with war department on the design of heavy machinery, familiar with mechanical and electrical transmission of power. At present in charge of drafting force, but desires administrative position in the development of machinery and manufacture of ammunitions of war.

K-346 Member, Executive and Mechanical engineer, graduate Massachusetts Institute of Technology, wide experience in railway operations, manufacturing and purchasing, desires position. Member Am. Ry. M. M. A., S. A. E.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured on request from Calvin W. Rice, Secretary of Am. Soc. M. E.

ASPHALT. Its history, manufacture and uses. Charles Ekstrand. Read before the Brooklyn Engineers' Club, May 13, 1915. Gift of author.

ATLANTIC INTRA-COASTAL WATERWAY. Official Survey Lines and present status of the work in its various sections. Philadelphia, 1915. Gift of Atlantic Deepener Waterways Association.

CATSKILL WATER SUPPLY. A general description. Sept. 1915. Gift of New York City Board of Water Supply.

NEW JERSEY BOARD OF PUBLIC UTILITY COMMISSIONERS. Financial and miscellaneous statistics compiled from the Annual Reports made by Public Utilities, 1913. Union Hill, N. J. 1915. Gift of New Jersey. Board of Public Utility Commissioners.

RESULTS OF EXPERIMENTS ON SEWER PIPE AND DRAIN TILE. E. H. Beckstrand. Utah Engineering Experiment Station. Bulletin no. 7. Salt Lake City, 1915. Gift of E. H. Beckstrand.

SOUND STEEL INGOTS AND RAILS. Sir Robert Hadfield and George K. Burgess. Reprinted from the Journal of Iron and Steel Institute, No. 1, 1915. London, 1915. Gift of Sir Robert Hadfield.

STEAM BOILER ECONOMY. William Kent, Ed. 2. New York, J. Wiley & Sons, 1915. Gift of Publishers.

Fourteen years have elapsed since the issue of the first edition of Dr. Kent's book. Naturally this edition differs greatly from the former one. This is well shown by the author's summary of improvements in modern practice and the practical results obtained. The wealth of references makes this of especial value. W. P. C.

VENTILATION OF SUEWAYS AND SUBWAY CARS. Robert G. Klotz. New York, 1915. Gift of author.

WATER POWERS OF CANADA. PROVINCE OF BRITISH COLUMBIA, G. R. G. Conway. Ottawa, 1915.

— THE PRAIRIE PROVINCES, MANITOBA, SASKATCHEWAN, ALBERTA, P. H. Mitchell. Ottawa, 1915. Gift of A. S. M. E.

YEAR BOOK OF BRITISH COLUMBIA AND MANUAL OF PROVINCIAL INFORMATION. Corporation Edition. Victoria, 1911. Gift of Sir Richard McBride.

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, \$3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, \$2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, \$1.00 ADDITIONAL

C 55. The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions

Entered as second-class matter, January 4, 1912, at the Postoffice, New York, N. Y., under the act of March 3, 1879

THIRTY-SIXTH ANNUAL MEETING

New York City, December 7 to 10, 1915

LIST OF TOPICS TO BE DISCUSSED

Abrasive Wheels	Hydraulic Power Plants
Accident Compensation	Large Electric Plants
Automatic Machine Tools	Locomotive Axles
By-Product Gas Producers	Oil Engine Vaporizers
Chimney Proportions	Orifice Gas Meters
Circulation in Boilers	Passenger Car Trucks
Electric Elevators	Prevention of Corrosion
Electrically-driven Tools	Private vs. Purchased Power
Engineer and Fire Insurance	Protection of Workers
Engineering and the Executive	Safety Methods
Fire Tube Boilers	Safety Principles
Foundations	Steam Pipe Coverings
Heating Textile Mills	Strength of Porcelain
Higher Steam Pressures	Strength of Stoneware
High Vacuum Condensers	Turbines vs. Engines

LIST OF AUTHORS OF PAPERS

Dan Adams, Mem. Am. Soc. M. E.	Ernest O. Hickstein, Jun. Am. Soc. M. E.
Allen H. Babcock	C. F. Hirschfeld, Jun. Am. Soc. M. E.
Paul A. Bancel, Jun. Am. Soc. M. E.	Louis Ilmer, Mem. Am. Soc. M. E.
J. S. Barstow	David Lindquist
James E. Boyd	Arthur H. Lymn
L. C. Brooks, Jun. Am. Soc. M. E.	L. B. McMillan, Jun. Am. Soc. M. E.
L. D. Burlingame, Mem. Am. Soc. M. E.	Charles T. Main, Mem. Am. Soc. M. E.
Robert Cramer, Mem. Am. Soc. M. E.	Anatole Mallet, Hon-Mem. Am. Soc. M. E.
F. W. Dean, Mem. Am. Soc. M. E.	A. L. Menzin, Assoc-Mem. Am. Soc. M. E.
Albert G. Duncan, Mem. Am. Soc. M. E.	Mark A. Replogle, Mem. Am. Soc. M. E.
Geo. H. Gibson, Mem. Am. Soc. M. E.	Frank W. Reynolds, Mem. Am. Soc. M. E.
Hollis Godfrey, Mem. Am. Soc. M. E.	Roy V. Wright, Mem. Am. Soc. M. E.

For program of the meeting see page VI.

MEETINGS OF LOCAL SECTIONS

December 1, St. Louis, Mo. The President of the American Society of Engineering Contractors will address this Section.

December 1, Buffalo, N. Y. Subject: Internal Conveyors, by Fay B. Williams, Engineer of the Lamson Company.

December 15, Buffalo, N. Y. Subject: Engineers in Politics, by C. E. Drayer, Secretary of the Cleveland Engineering Society.

December 16, Cincinnati, O. F. L. Raschig will discuss the paper on Engineering Features of the Panama Pacific International Exposition by Guy L. Bayley, Mem. Am. Soc. M. E., using slides which Mr. Bayley made at the Engineering Congress at San Francisco.

December 16, Minnesota. Subject: Engineering Education in the British Isles, by John J. Flather. Dinner will be served at 6:30.

December 18, St. Louis, Mo. The Local Section of St. Louis will hold a dinner for the introduction of new members.

January 5, Buffalo, N. Y. Subject: The History of Iron, by Dr. J. A. Mathews, Mem. Am. Soc. M. E., of the Halcomb Steel Company.

April 11-14, New Orleans, La. Spring Meeting of The American Society of Mechanical Engineers.

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 37

December 1915

Number 12

THE ANNUAL MEETING

THE thirty-sixth Annual Meeting will be held in the Engineering Societies building, 29 West 39th Street, New York, beginning on Tuesday, December 7, and ending on Friday, December 10. The attendance at annual meetings has been increasing steadily and last year's was the largest in the history of the Society. It is hoped that all members who find it possible to come to New York at the time of the meeting will do so, as this affords the greatest opportunity of the year for extending one's acquaintanceship. The Committee on Meetings has provided a program so varied that some part of it at least cannot fail to interest every member. The details of the program follow on another page, where the various professional papers are listed. Copies of these papers will be ready in pamphlet form in advance of the meeting, and any of them will be sent, free of charge, to any member asking for them previous to the time of the meeting.

Headquarters will be open for registration at 2 p.m. on Tuesday, December 7. In the evening the President, Dr. John A. Brashear, will give the annual address, on Science in its Relation to Engineering, followed by a reception to the President, Present-elect, ladies, members and guests. During his term as president Dr. Brashear has been very active among the membership. He not only has traversed the continent twice, but has made many other extended trips for the purpose of meeting members in different parts of the country. His lectures have delighted scores of audiences, and one of the anticipations of the present meeting is the pleasure of greeting and hearing Dr. Brashear at Tuesday evening's opening session.

ENTERTAINMENT FEATURES

On Wednesday afternoon, December 8, a reception and tea will be given in the rooms of the Society to the visiting ladies, members and guests. This will be under the auspices of the Ladies Committee and is one of the delightful and important social features of the Annual Meeting. It is usual to close the afternoon with dancing. All are cordially invited to attend.

Special attention is called to the Smoker on Wednesday evening, which is to be held at the Society headquarters. This is distinctly a members' reunion, having for its chief function the opportunity to extend one's acquaintanceship and to secure to the fullest extent the benefits which come from time spent together in an assemblage of engineers from all sections of the country. No program is to be announced in advance, but the New York Committee gives every assurance of a good time. The usual Wednesday evening lecture of the Annual Meeting will this year be omitted.

The dinner and dance on Thursday evening will be held in the Grand Ball Room of the Hotel Astor. An attendance of over 400 is expected and the preparations for this event, which have been completed by the local committee, assure an event fully equal to the reunions of past years, which have been so important and successful a feature of the program. In view of the fact that the members in previous years have been very late in arranging for attendance at the Thursday evening reunion, the Committee has this year provided for a special price of \$5 per person to all who purchase tickets before 6 P.M. on Wednesday, December 8. After this time, the price of the tickets for the dinner and dance will be \$6 per person. Early notification with regard to purchase of tickets should be made at headquarters.

EXCURSIONS

The plan this year will be to have a few excursions of exceptional interest rather than a multiplicity of less important trips. Visits are contemplated to the power and elevator plants of the Municipal and Woolworth buildings; to the 74th Street station of the Interborough Rapid Transit Company, where turbines of 40,000 h.p. are now running; and to the Brooklyn Navy Yard, where the battleship Brooklyn, designed to be the most powerful armored afloat, is under construction. A trip is also planned to one of New York's leading moving picture studios and to an aeronautical plant in the vicinity which is of interest.

PROGRAM OF THE ANNUAL MEETING

Tuesday Afternoon, December 7

Conference of Local Sections, 12:30 p.m. All Council members and official delegates of the Society's fourteen sections will meet to discuss ways and means for making the local sections of the utmost benefit to the membership. Other conferences of local sections will be held at intervals during the convention.

Registration Bureau opens, 2 p.m.
Council Meeting, 2 p.m.

Tuesday Evening

Opening Session: Address by Dr. John A. Brashear, President of the Society, on Science in its Relation to Engineering.

Reception by the Society to the President, President-elect, ladies, members and guests.

Wednesday Morning, December 8

BUSINESS MEETING

Reports of the Council and Standing Committees. Constitutional Amendments. Report of Committee on Standardization of Special Threads for Fixtures and Fittings and announcement of Report of Power Test Committee. New Business.

Immediately following the business meeting, the Society will honor the memory of the late Dr. Frederick W. Taylor, Past-President. The proceedings will consist of a report by a special committee appointed by the President to represent the Society at the Taylor Memorial Meeting held in Philadelphia on October 22 under the auspices of the Society to Promote the Science of Management.

PROFESSIONAL SESSION

Papers to be presented by title only

GAS PRODUCERS WITH BY-PRODUCT RECOVERY, Arthur H. Lynn

THE APPLICATION OF ENGINEERING METHODS TO THE PROBLEMS OF THE EXECUTIVE, DIRECTOR AND TRUSTEE, Hollis Godfrey, Mem. Am. Soc. M. E.

MODERN ELECTRIC ELEVATOR AND ELEVATOR PROBLEMS, David Lindquist

These three foregoing papers contributed by the New York local committee

TURBINES VS. ENGINES IN UNITS OF SMALL CAPACITIES, J. S. Barstow

Contributed by the Philadelphia local committee

THE CONNORS CREEK PLANT OF THE DETROIT EDISON COMPANY, C. F. Hirshfeld, Jun. Am. Soc. M. E.

Contributed by the Buffalo local committee

PROPORTIONING CHIMNEYS ON A GAS BASIS, A. L. Menzies, Assoc. Mem. Am. Soc. M. E.

The foregoing papers which are to be presented by title will be distributed at the meeting in pamphlet form, and written discussion upon them solicited for publication in The Journal. There will be no opportunity for oral discussion of these papers.

STEAM POWER

Papers to be presented by abstract

DESIGN OF FIRE TUBE BOILERS AND STEAM DRUMS, F. W. Dean, Mem. Am. Soc. M. E.

HIGHER STEAM PRESSURES, Robert Cramer, Mem. Am. Soc. M. E.

A NOVEL METHOD OF HANDLING BOILERS TO PREVENT CORROSION AND SCALE, Allen H. Babcock

This paper in preliminary form was presented before the San Francisco local section, December, 1914

Wednesday Afternoon

SIMULTANEOUS SESSIONS

RAILROAD

Papers contributed by the Sub-Committee on Railroads

OPERATION OF PARALLEL AND RADIAL AXLES OF A LOCOMOTIVE BY A SINGLE SET OF CYLINDERS, Anatole Mallet, Hon. Mem. Am. Soc. M. E.

FOUR-WHEEL TRUCKS FOR PASSENGER CARS, Roy V. Wright, Mem. Am. Soc. M. E.

TEXTILE

Papers contributed by the Sub-Committee on Textiles

HEATING BY FORCED CIRCULATION OF HOT WATER IN TEXTILE MILLS, Albert G. Duncan, Mem. Am. Soc. M. E.

RELATIVE VALUE OF PRIVATE AND PURCHASED ELECTRIC POWER FOR TEXTILE MILLS, Frank W. Reynolds, Mem. Am. Soc. M. E., and Dan Adams, Mem. Am. Soc. M. E.

MACHINE SHOP

Papers contributed by the Sub-Committee on Machine Shop Practice

AUTOMATIC MECHANICAL CONTROL OF LATHEES AND SCREW MACHINES, L. D. Burlingame, Mem. Am. Soc. M. E.

ELECTRIC OPERATION AND AUTOMATIC ELECTRIC CONTROL FOR MACHINE TOOLS, L. C. Brooks, Jun. Am. Soc. M. E.

REPORT ON CODE FOR ABRASIVE WHEELS.

During the afternoon a reception and tea will be given in the rooms of the Society to the visiting ladies, members and guests under the auspices of the Ladies' Committee. This will be one of the important social features of the Annual Meeting and all are cordially invited to attend.

Conference of Student Branches.

Wednesday Evening

SMOKER

A departure will be made from the usual Wednesday evening lecture, by holding a Smoker in the rooms of the Society. This will be a get-together, get-acquainted meeting, in charge of the New York local committee, to which every member is invited for a social evening and a good time.

Thursday Morning, December 9

SIMULTANEOUS SESSIONS

POWER PLANT

THE HEAT INSULATING PROPERTIES OF COMMERCIAL STEAM PIPE COVERINGS, L. B. McMillan, Jun. Am. Soc. M. E.

PERFORMANCE AND DESIGN OF HIGH VACUUM SURFACE CONDENSERS, Geo. H. Gibson, Mem. Am. Soc. M. E., and Paul A. Bancel, Jun. Am. Soc. M. E.

CIRCULATION IN HORIZONTAL WATER TUBE BOILERS, Paul A. Bancel, Jun. Am. Soc. M. E.

UNIQUE HYDRAULIC POWER PLANT AT THE HENRY FORD FARMS, Mark A. Replogle, Mem. Am. Soc. M. E.

MISCELLANEOUS

THE FLOW OF AIR THROUGH THIN-PLATE ORIFICES, Ernest O. Hickstein, Jun. Am. Soc. M. E.

This paper is the Junior Prize Paper for 1915, and bears the further distinction of being the first paper to receive a prize from The American Society of Mechanical Engineers. A fund for Junior and Student prizes was recently established by a member of the Society.

ELASTICITY AND STRENGTH OF STONEWARE AND PORCELAIN, James E. Boyd

Contributed by the Research Committee

FOUNDATIONS, Charles T. Main, Mem. Am. Soc. M. E.

Contributed by the Sub-Committee on Industrial Building

OIL ENGINE VAPORIZER PROPORTIONS, Lonis Illmer, Mem.
Am. Soc. M. E.

Thursday Afternoon

This afternoon is left free for excursions. Instead of providing for a large number of excursions, as in previous years, the Local Committee has arranged for a few of exceptional interest which it is expected large groups of members and guests will attend.

Thursday Evening

Annual Reunion, Dinner and Dance at Hotel Astor.

Friday Morning, December 10

INDUSTRIAL SAFETY

STANDARDIZATION OF SAFETY PRINCIPLES, Carl M. Hansen.

Other papers are expected to be presented on the following subjects: Modern Movement for Safety from Standpoint of Manufacturer; Methods of Reducing Accidents Through Cooperative Movements of Workmen; and Compulsory Compensation for Accidents by Law.

ABSTRACTS OF PAPERS

In the November issue of the Journal brief abstracts were printed of the majority of the papers to be presented at the Annual Meeting. Below are given abstracts of four additional papers which are scheduled on the above program. These abstracts will furnish an idea of the contents of the papers and should be of assistance to members in selecting the papers of interest to them or for purposes of discussion.

HEATING BY FORCED CIRCULATION OF HOT WATER IN TEXTILE MILLS

By ALBERT GREENE DUNCAN, MEM. AM. SOC. M. E.

This paper treats of the method of using hot water to heat, through direct heating surface, the various rooms of a large textile mill, the water being heated by live or exhaust steam in closed heaters in a central plant, and the hot water being distributed by forced circulation.

The regulation of heat in the various departments is in charge of the power plant engineer, long distance reading thermometers being installed in the power house.

Owing to the configuration of the plant, the heating system was installed in two sections, each section being taken care of by its own heater and pump, and there being a standby unit for emergency.

Since the installation of the system in 1912-13 extensive readings of temperature, humidity, amount of radiation in service, etc., have been made. These records bring out a number of interesting points and show:

- a. The benefit of double windows in a plant offsets their cost many times.
- b. Openings from heated rooms to entry ways and elevator shafts are a constant source of loss.
- c. If study and regulation is made along proper lines, except in extreme weather, heating can be confined to the lower floors of a textile mill, to the weaving and carding departments and to portions of the mill where very little machinery is in operation.

RELATIVE VALUE OF PRIVATE AND PURCHASED ELECTRIC POWER FOR TEXTILE MILLS.

By FRANK W. REYNOLDS, MEM. AM. SOC. M. E.

AND DAN. ADAMS, MEM. AM. SOC. M. E.

Average rates for purchased power are higher by a small amount than the cost of generating power in a new isolated plant for a textile mill when there are no adverse conditions. The size of the plant and the load factor have little influence on the relative cost. A fair demand for steam in the process usually gives the isolated plant a decided advantage, but the use of steam for heating and for small demands such as slashing is relatively unimportant. The saving from the use of exhaust steam is apt to be overestimated unless the diversity factor and variable demand are studied carefully.

In the majority of new developments where reliable purchased power is available, the saving from private power will be too small to make the power plant investment attractive. The purchase of power does not wipe out existing fixed charges on a going plant, and therefore cannot compete in power cost with a plant already built, except in the case of additions or extensive renewals or very poor operating economy. The reliability of most purchased power is as good or better than that of an isolated plant without relay capacity.

In general, purchased power is desirable for textile mills, but the desirability must be weighed against the small additional cost in the average case.

A NOVEL METHOD OF HANDLING BOILERS TO PREVENT CORROSION AND SCALE

By ALLEN H. BABCOCK.

The author gives an account of the difficulties experienced from corrosion in the boilers of the Fruitvale power house of the Southern Pacific Company, California, which were so serious that in 18 months one-third of the tubes required replacing. Various efforts were made to check the corrosion, without success, until the author learned of the investigations and experiments conducted by Commander Frank H. Lyon, U. S. N., on the treatment of feedwater. This work by Commander Lyon led to the proposal of a compound known as the "Navy Standard Boiler Compound," the main element of which is sodium carbonate, but which contains also trisodium phosphate, dextrine and a tannin compound; and a determination of the effect on corrosion of feedwater having different degrees of alkalinity. The compound was tried out at Fruitvale station with the result that corrosion troubles practically ceased.

A further trial of the compound was made, with favorable results, in one of the worst locomotive water districts on the Southern Pacific Lines, and also in other power plants of the system. An account is given of these experiences and of the modifications made to reduce foaming in locomotive boilers.

The paper outlines the features of the long investigation by Commander Lyon of the causes of corrosion and means for overcoming this trouble, which led to the discovery of the Navy compound. Full directions are given for using the Navy compound.

PERFORMANCE AND DESIGN OF HIGH VACUUM SURFACE CONDENSERS

By GEO. H. GIBSON, MEM. AM. SOC. M. E.
AND PAUL A. BANCEL, JUN., AM. SOC. M. E.

Heat transmission in surface condensers presents anomalies of which a consistent explanation has not been offered. The coefficients of heat transmission secured in commercial condensers are far short of those realized in experimental laboratory condensers and, moreover, the coefficients obtained under summer conditions are always better than those obtained from the same condensers in winter, with colder circulating water. Examination of a number of tests of condensers with varying conditions shows, however, that the depression of the air pump suction temperature below the steam temperature corresponding to the vacuum is related to the average coefficient of transmission, or relative proportion of the active zone of condensation, in a definite way. This depression is due partly to fall in pressure and expansion of the steam incidental to its flow through the resistance presented by the condenser, and is also implied in the increasing partial pressure of the air as the latter nears the air pump suction opening. If the pressure at the inlet of the condenser is known and the drop can be calculated, the pressure at the air pump suction can be predetermined; and, taking into consideration the fact that the virtual displacement of the air pump is approximately constant and that the air must therefore be reduced to a fixed volume regardless of vacuum, the temperature of the air pump suction with a given amount of air can be calculated. This, in connection with the inlet steam temperature is, as already mentioned, an indication of the average coefficient of transmission to be expected, which in turn makes it possible to estimate what water temperature will be necessary in order to carry the same load at a different vacuum, or vice versa. For a given condenser, the effects of changes in any of the following factors: load; vacuum; water temperature; rate of flow, and air pump capacity, can therefore be foretold if its performance under one set of conditions is known.

At high vacuums the spacing and the number of rows of tubes, which determine the pneumatic resistance of the steam flow path or paths, have great influence upon the average efficiency of the surface in transmitting heat. Since the controlling resistance is on the air-steam side of the tubes in the air-drowned inactive zone of the condenser, increase in water velocity is of little benefit in these tubes. In fact, this velocity may be decreased and the velocity in the tubes of the active zone increased where it will do some good without added power expenditure. Zone condensers of this kind are illustrated.

COLLEGE REUNIONS DURING THE ANNUAL MEETING

It has been customary during the past few years for the New York Alumni Associations of various colleges where engineering courses are given to hold a reunion on the last evening of the Annual Meeting (which this year will be December 10), to welcome the large number of out-of-town alumni. Complete details of final arrangements will be given in the program distributed

at the Annual Meeting. The following reunions have been planned tentatively for that evening:

BROWN UNIVERSITY

The Engineering Alumni of Brown University will hold a reunion in the form of a Smoker. Those desiring to attend are requested to communicate with Mr. Francis P. Davis, care of American Telephone & Telegraph Co., 15 Dey St., New York.

CORNELL UNIVERSITY

Mechanical Engineers from Cornell University have arranged for their annual dinner at the Cornell University Club, 65 Park Ave., New York. Definite details for the program have not yet been decided, but last year's plan of having appropriate special features for the entertainment of those in attendance will be carried out. Further information may be obtained from Mr. F. Kingsley, care of the Electric Railway Journal, 239 West 39th St., New York.

LEHIGH UNIVERSITY

The New York Lehigh Club will hold an informal reunion dinner and smoker at the Machinery Club, Hudson Terminal Building, 50 Church Street, New York, at 6:30 P. M. Mr. Homer D. Williams of the Class of '90 will be the Guest of Honor. Further information may be had from Mr. H. H. Scovil, care of the Railway Steel Spring Co., 30 Church Street, New York.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

While no formal reunion has been arranged, the members of the Technology Club will go in a body to the Chemists' Club, 52 East 41st St., New York, where Dr. Richard C. MacLauren, President of Massachusetts Institute of Technology will make an address. On December 11 a luncheon and reception will be tendered to Dr. MacLauren at the Technology Club of New York, 17 Gramercy Park. All "Tech." men are invited to participate in these events. Information will be furnished by Mr. Thomas C. Desmond, 17 Gramercy Park, New York.

POLYTECHNIC INSTITUTE OF BROOKLYN

The Mechanical Engineering Alumni of the Polytechnic Institute of Brooklyn will hold a reunion in the rooms of the Society. An invitation to attend is extended to all members of the Society as well as the Alumni of Polytechnic Institute. Detailed information may be obtained from Mr. H. G. Tyler, Polytechnic Institute of Brooklyn.

PURDUE UNIVERSITY

The Purdue Club of New York will hold an informal reunion dinner and smoker at the Phi Gamma Delta Club, 34 West 44th Street, New York. A number of celebrities are expected and all Purdue men are urged to attend. Further information may be obtained from Mr. J. B. Thiess, 463 West Street, New York.

UNIVERSITY OF ILLINOIS

The Alumni of the University of Illinois will hold a reunion dinner and smoker at the Chemists' Club, 52 East 41st Street, New York. Information may be obtained from Mr. J. A. Kinkead, care of the Parkesburg Iron Company, 30 Church Street, New York.

STEVENS INSTITUTE OF TECHNOLOGY

All members of The American Society of Mechanical Engineers and their guests are cordially invited to join with the Alumni of Stevens Institute of Technology in their annual dinner and theatre party on Friday evening, December 10, 1915, at the New Amsterdam

Theatre, 42nd Street, west of Broadway. After the show, there will be a supper and dance at the Hotel Astor. Tickets may be obtained from the Tyson Company, Hotel Astor, and further information from Mr. B. Franklin Hart, Jr., 50 Church Street, New York.

WORCESTER POLYTECHNIC INSTITUTE

The New York Alumni of Worcester Polytechnic Institute will hold their Annual Dinner at 6 P. M. at the Hotel St. Dennis, Broadway and 11th Street, New York. Special features are being arranged to make this a "banner" event. Information may be had from Mr. Frank O. Price, Pratt Institute, Brooklyn, N. Y.

REPORTS OF STANDING COMMITTEES

Presented at the Council Meeting, November 12, 1915

REPORT OF THE COMMITTEE ON CONSTITUTION AND BY-LAWS

During the past year the Committee on Constitution and By-Laws has considered matters referred to it from the Council covering the following revisions:

B-27 A Nominating Committee of five members, not members of the Council, shall be appointed before February first of each year by the President. The Secretary shall publish the names of this Committee in the March issue of The Journal, together with a request to the voting membership of the Society that they recommend to the Committee the names of eligible persons for the elective offices to be filled at the next election. This Committee shall deliver to the Secretary in writing between the first and the fifteenth of June the names of its nominees for the various elective offices next falling vacant under the Constitution, together with the written consent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of the Committee in the July issue of The Journal.

B-28 A special Nominating Committee, if organized, shall on or before October fifteenth, present to the Secretary the names of its nominees for the elective offices next falling vacant under the Constitution, together with the written consent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of this Committee in the November issue of The Journal.

Nominating Committee.

(Proposed) C-48 Special Nominating Committee:

Any group forming one per cent of the persons entitled to vote may constitute itself a Special Nominating Committee, with the same powers as the Annual Nominating Committee appointed by the President.

The proposed amendment to the Constitution was presented at the Spring Meeting in Buffalo and will come up for any suggested revision and amendment at the Annual Meeting in December.

The Committee has under consideration an amendment to By-Law 12 which the Council has requested be brought into harmony with the provisions for the nomination and balloting for officers of the Society.

By-Law 47 is a new By-Law for a uniform policy in the matter of reports of committees.

B-47 All written reports of all committees shall be presented to the Council. Each written report of every Com-

mittee must be approved in writing by at least a majority of the members of that Committee, before it is presented to the Council. A member of a Committee who disagrees with the action of a majority of that Committee may express his disagreement over his signature, either on the report of the Committee or in a minority report. The minority report of any member of a Committee if offered, shall be presented at the same time that the report of that Committee is presented to the Council.

All reports of Committees must be first received by the Council who shall prescribe the manner in which they shall be presented to the Membership of the Society and be made public and printed.

The matter of professional reports has been further considered in a proposed amendment to C-54 of the Constitution to read as follows. This amendment was also presented at the Spring Meeting of the Society:

(Proposed) C-54 The Society shall claim the exclusive copyright to any reports of its duly appointed committees. The Council shall waive such copyright for specific reports. The Society shall copyright all papers read before the Society, printing thereon in each instance that the paper may be reprinted by anyone after the same has been read before the Society, provided that due credit be acknowledged to the Society and the author. The policy of the Society shall be to give the professional and scientific papers read before it the widest circulation possible, with the view of making the work of the Society known, encouraging engineering progress and extending the professional reputation of its members.

Rule 16 is obsolete and has been cancelled, provision being made for it in By-Law 33.

Rule 16—Ballots for amendments to the Constitution shall be canvassed and announced in the same manner as the ballots for officers of the Society.

F. R. HUTTON, *Acting Chairman.*

REPORT OF THE FINANCE COMMITTEE

Your Finance Committee reports that the income of the Society for the year ending September 30, 1915, was \$117,628.60. The total expenditures chargeable to income were \$118,846.79, leaving an excess over income of \$28,781.81. Out of this excess it is necessary to reserve \$2,000.00 for completing 1915 condensed catalogues, \$100.00 for distributing Vol. 36, Transactions, \$200.00 on account of expenses of San

Francisco meeting, leaving a balance of \$26,481.81, which we recommend be turned into the Reserve Fund. It is further recommended that all appropriations in excess of actual expenditures be cancelled.

The expenditure of the Society per member for the fiscal year just closed is as follows:

General Salaries	\$ 2.24
Rent, library, supplies, etc.	1.73
Committees on Membership and Increase of Membership	1.00
Sections56
Employment Bulletin18
Council contingencies17
House Committee27
Annual and Spring meetings	1.24
Year Book62
Journal and Condensed Catalogue	6.70
Transactions	1.77
Other activities	1.76

Making a total of\$18.24

The Budget Appropriation for the current year equals per member approximately \$20.50.

Your Finance Committee recommends the following budget for the year 1916:

Finance Committee.....	\$29,000.00
Membership Committee.....	2,000.00
Council	12,200.00
Increase of Membership Committee....	6,000.00
House Committee.....	1,700.00
Meetings Committee.....	7,850.00
Publications	65,300.00
Research Committee.....	250.00
Public Relations.....	500.00
Sales	8,650.00
Student Branches.....	750.00
Junior Prize.....	100.00

Total.....\$134,300.00

The estimated income for the year is placed at \$149,570.00.

Appended will be found a report of the accounts of the Society as shown in the books for the fiscal year ending Sept. 30, 1915.

Respectfully submitted,

R. M. DIXON, *Chm.*, }
W. H. MARSHALL, } *Finance Committee.*
A. E. FORSTALL, }

Mr. R. M. DIXON,

CHAIRMAN, FINANCE COMMITTEE

Dear Sir: In accordance with your instructions, we have examined the books and accounts of The American Society of Mechanical Engineers, for the twelve months ended September 30, 1915.

The results of this examination are set forth in the three exhibits, attached hereto, as follows:

Exhibit A Balance Sheet, September 30, 1915.

Exhibit B Income and Expenses for the twelve months ended September 30, 1915.

Exhibit C Receipts and Disbursements for the twelve months ended September 30, 1915.

We hereby certify that the accompanying Balance Sheet is a true exhibit of its financial conditions as of September 30, 1915, and that the attached statements of Income and Expenses, and Receipts and Disbursements are correct.

Respectfully submitted,

WM. J. STRUSS & Co.,
Certified Public Accountants.

REPORT OF HOUSE COMMITTEE

During the year the portraits of honorary members have been completed and hung in the rooms of the Society. The inventory of pictures, books, publications, stores and equipment has been brought up to date.

Sufficient funds have been saved from the Committee's appropriation to replace on an advantageous basis the worn-out typewriters with new ones, also to provide a metal fire-proof cabinet for the safe keeping of the card records of accounts of members.

Inasmuch as certain members have criticized the Society for not having a special room for out-of-town members to be used for special work, the Committee has provided for all conceivable present demands by the use of the Council room, and until greater demand is made for an additional room with the special purpose of serving out-of-town members, the Council room will be used for that purpose.

Plans have been prepared and estimates secured for the removal of partitions in rooms Nos. 1109 to 1112, so as to make one large room, providing more room and a more efficient arrangement for the members of the staff. Recommendations have been made to the Council for the necessary appropriations to execute this work.

Estimates have also been secured for enlarging the doorways between the elevator entrance corridor and the Council room, and the room adjacent to the Council room. Estimates have also been secured for re-decorating and re-arranging the elevator corridor of the Society.

It is believed these changes will add to the cheerfulness and usefulness of the Society's rooms.

The Society's property in charge of the Committee has been maintained to its previous high degree of permanency

in so far as the funds at the disposal of the Committee will permit.

REPORT OF THE LIBRARY COMMITTEE

During the year ended September 30, 1915, there have been added to the library of the Society 775 volumes and 65 pamphlets. Two large collections have been presented to the Society; the first, the library of the late Horace See, Past President of the Society, a leading naval architect and marine engineer, was presented by John Philp, and comprises a large number of volumes on naval architecture and marine engines. The second, recently received as a gift from the widow of David N. Melvin, is the general library of a working engineer, especially strong in applied chemistry.

During the year the management of the library has been taken over by the United Engineering Society. All purchased books and periodicals will be the property of the United Engineering Society; gifts will be, as formerly, the property of the Founder Society to which the gift is made.

The United Engineering Society has established a Library Service Bureau, to have sole charge of the research work for out-of-town members. This Bureau, self-supporting, will conduct researches, make translations, copies and abstracts, at a charge covering the cost.

The Catalogue of Technical Periodicals in the Libraries of New York and vicinity has been published, as the first bibliographical contribution from the library, and has received favorable comment from engineers, librarians, and the technical press.

The attendance during the year was 12,749. The extension of the evening hour of closing from nine o'clock to ten o'clock has been welcomed by our readers.

During the year additional shelving to accommodate 20,000 volumes has been added; wooden cases for the storage of periodicals awaiting binding have also been purchased.

Respectfully submitted,

LEONARD WALDO, <i>Chmn.</i>	} <i>Library Committee</i>

REPORT OF THE COMMITTEE ON MEETINGS

The Meetings Committee has met five times since the Annual Meeting of 1914, and will probably have several more committee meetings before the next Annual Meeting of the Society.

The movement inaugurated last year to complete the work of preparation for each meeting of the Society earlier than in former years has not been carried on with entire success, although some measure of progress has been achieved. It appears to be difficult to impress upon those not having had experience with meetings, the time necessary to pass upon, put in type, properly read proof and prepare illustrations for papers.

Three of the papers, out of five provided for the extra meeting in September were received late, and at a time when

several members of the Meetings Committee and of the Society staff were not readily accessible, owing to the vacation habit. This situation made it necessary to put these papers in type before submitting them to the committee for approval and did not permit adequate time for revision. One paper which was deemed to need considerable revising could not be returned to its author for revision. The Editor did this work, but it is to be regretted that the author could not have been given an opportunity to do this himself. The time required for communication with San Francisco aggravated the situation in this instance.

A time limit should be fixed for receipt of papers from local committees and, upon its expiration, the Meetings Committee should proceed to complete the program, substituting for those expected, but not in hand other papers if necessary or desirable in its judgment.

The Annual Meeting for 1914 had the largest attendance in the history of the Society. The features of the convention were an all-day meeting on the general subject of the Engineer in Public Service, at which nine papers were presented through the efforts of the Public Relations Committee; a series of largely attended conferences for the discussion of the report of the Boiler Code Committee; and whole sessions by the Railroad and Iron and Steel Committees.

The Spring Meeting was held June 22 to 25, all sessions being held in Buffalo except that of Wednesday, June 23. This session, which included the business meeting, was held at Niagara Falls. Committee reports and professional papers were also presented at this session. On Wednesday evening an admirable illustrated address was delivered by Dr. F. H. Newell on The Engineer as a Citizen.

There were two simultaneous sessions Thursday morning for presentation of papers and a final one Friday forenoon.

The formal social feature was the reception and dance on Thursday evening, but the local committee provided in many other ways for the pleasure of the visiting members, their families and guests. The excellent arrangements for sight-seeing and professional inspection trips at Niagara and in Buffalo contributed greatly to the success of the meeting.

In conformity with the other national societies a meeting was held in San Francisco preceding the International Engineering Congress and thirty-five of our members joined the party on the Engineers' special train for San Francisco. The committee was fortunate in securing two authoritative papers on the engineering features of the Exposition and the exhibits. Two papers were presented upon the oil engine, of general interest on the Pacific Slope, and one on the strength of gear teeth.

Plans are fairly well advanced at this time (September 1915) for the Annual Meeting to be held in December.

Enough papers are now in hand for four general sessions. A special session on Industrial Safety is to be arranged by the Sub-Committee on Protection of Industrial Workers. The Hon. John Price Jackson of that committee has consented to take the lead in arranging the program. The sub-committees on Machine Shop Practice, Textiles, and Railroads are each planning for sessions.

The sub-committees of the Meetings Committee have been reorganized. Two of these, for which there seems to be little work at present, have been discontinued, namely, those on Administration and Iron and Steel. In the case of some others, the chairman or other members have changed.

The Committee feels that special efforts should be made to

maintain the interest of engineers in the varied lines of work comprised in the membership and particularly of those who are so situated that their personal participation in the meetings is not practicable. The suggestion in this connection is submitted for consideration of the Council, that a larger number of papers be published by the Society, and that the publications may include some papers to be printed, with written discussion, which will be read by title only at the meetings. This will make it possible to place on record the results of research or analysis of permanent value, although the character of these papers may not be such as to make their oral presentation at a meeting of general interest to the membership at large. It is realized that this project involves larger expenditures, and owing to this the Meetings Committee does not venture to urge it upon the Council, but considers it a duty to present the question for consideration.

Respectfully submitted,

REPORT OF COMMITTEE ON MEMBERSHIP

The Committee on Membership held nine meetings during the year 1914-1915.

The number of applications considered in the transaction of its work and a summary showing the action taken, follows:

Applications pending Oct. 1, 1914.....	191
Applications received during fiscal year.....	1069

Total 1260

The following action was taken on these applications:	
Recommended for membership.....	736
Withdrawn for various reasons.....	2
Deferred indefinitely.....	13
Denied promotion.....	3
Deferred for special investigation.....	14
In regular course of procedure.....	492

Total 1260

Reinstatement deferred.....	1
Reinstatements and Reconsiderations pending.....	11

Those recommended for membership were divided into the following gradings:

Members	271
Promotion to Member.....	23
Associates	38
Associate-Members	191
Promotion to Associate-Member.....	18
Juniors	195

Total 736

The reinstatement of nine members was recommended to the Council.

George A. Orrok, who was appointed a member of the Committee at the beginning of the year, found it necessary to resign and the Committee accepted his resignation with much regret. Dr. Charles E. Lucke accepted an appointment to serve the balance of Mr. Orrok's term, though it was

necessary for him to make considerable personal sacrifice in order to serve the Society in this capacity.

REPORT OF THE PUBLICATION COMMITTEE

In the last annual report of the Publication Committee, there was a discussion of plans which had been proposed for eliminating the duplicate publication of papers in Transactions and The Journal. During the previous year The Journal had been published in a form whereby it could be bound at the end of the year and constitute the Transactions of the Society. At the same time, the advance papers for meetings were printed in pamphlet form as usual, for which the type was held to permit the publication of the annual volume of Transactions in the 6 by 9 library size.

In view of letters of criticism and suggestions received from the membership, it was evident that there was a very earnest desire on the part of many members to have the Transactions continued as a separate volume, and accordingly, by direction of the Council, Volume 36 was issued, leaving no break in the continuity in the series of these volumes.

The decision to issue Volume 36 of Transactions and the possibility of the continuance of Transactions led to a change in the presentation of matter in The Journal, in that the Annual and Spring meeting papers, which go to the entire membership in complete form in Transactions, and are available at all times in pamphlet form to those who desire them, have been condensed as published in The Journal. The Journal serves the purpose of a current periodical which contains accounts of meetings immediately after the meetings have been held.

On the other hand, the papers presented at local meetings of the Society, which, as a general thing, have not been included in Transactions, have had more complete publication in The Journal. Every effort has been made to render comprehensive reports of these local meetings.

The publication plan which has been followed the past year is as follows:

1. Advance copies of papers for Annual and Spring meetings printed in pamphlet form (6 by 9 size).
2. Very brief abstracts of these papers appear in The Journal previous to the meeting with the statement that pamphlet copies will be sent free to any member asking for them.
3. After the meeting a running account of the proceedings of the meeting is published in The Journal, which includes copious abstracts of the papers and discussion.
4. The complete papers for the Annual and Spring meetings are published in the annual volume of Transactions. When this volume is printed additional sheets are run on the press and bound up in pamphlet form as revises, which are placed in the stock room for future sales.
5. Papers presented at local meetings are published in The Journal in either abstracted or complete form.

The following resolutions have been adopted by the Com-

mittee and with the approval of the Council will constitute the policy of the Publication Committee for the ensuing year. It was moved that the Publication Committee recommend to the Council:

TRANSACTIONS

1. That the publication of the annual volume of Transactions be continued.
2. That it be published in the same size and binding as heretofore.
3. That it shall contain, subject to the approval of the Publication Committee, all of the papers and discussions presented at meetings of the Society (not including section meetings), and technical reports of Committees; and shall contain a syllabus of each paper, summarizing the essential facts and conclusions.
4. That it shall contain all the papers and discussions presented at section meetings which in the opinion of the Publication Committee are of sufficient merit.

REVISES

That additional revised copies of the papers and discussion be printed and bound in pamphlet form at the earliest practicable date. A charge will be made for such pamphlets.

ADVANCE PAPERS

That papers for the meetings of the Society be printed in pamphlet form in advance, as heretofore, and be sent to members gratis upon request, a notice of these papers with syllabi, being printed in The Journal one month before meetings.

THE JOURNAL

1. That The Journal be published monthly as heretofore, but with the view to making it a semi-monthly or a weekly as soon as the amount of matter to be handled requires it and funds for that purpose are available.
2. That the size of The Journal shall for the present remain as it now is.
3. That The Journal shall contain:
 - a. All of the papers and discussion presented at regular meetings of the Society, preferably in substantially complete form, or adequately abstracted, according to the character of the paper, as soon after the meetings as possible.
 - b. Papers, or abstracts, with discussion, presented at meetings of Local Sections.
 - c. Announcements and reports upon Society affairs and incidents, employment bulletin, library notes, personal notes, etc.
 - d. Department for contributed discussions on papers previously published, or new matter.
 - e. Members correspondence department, including suggestions on Society affairs.
 - f. Review of World's Technical Press.
 - g. Review of technical books, by experts selected by the Committee.

The Committee adopt as a policy that the Editor shall coöperate with the author to present all papers and discussions as concisely as possible, consistent with clearness and completeness. This not only adds to the utility of the paper, but will make possible the publication of more papers in complete form. An abstract should be done by the author. The editor will coöperate toward securing uniformity.

The practice has been to publish the papers in Transactions in full. In The Journal the present practice is to reduce the papers and discussion by abstracting about 50 per cent. To have published them complete in The Journal during the past year would have cost \$3000 additional.

The Committee believes that the members will be best served by publishing papers in The Journal in substantially complete form, and that the additional cost of approximately \$3000 would be fully justified by the enhanced value of The Journal.

The Committee, however, would make an exception of certain types of papers—notably voluminous research papers which may be more acceptably presented in abstract.

The point is often raised that there would be economy in printing The Journal and Transactions with the same size page to avoid the necessity of resetting the type. The 6 by 9 size is undoubtedly more acceptable to the members for Transactions and for the advance papers than the 9 by 12 size would be, and the 9 by 12 size is far more advantageous for The Journal, both on the score of greater income from advertising and lower cost of production.

An examination of the bills for the last volume of Transactions shows the additional cost per page for resetting the type to be \$0.75. The cost for the total edition delivered to the members is \$10.00 per page. The additional cost, therefore, for resetting amounts to 7½ per cent.

There are practical reasons, such as the wear of the type on a long run of The Journal and the uneven appearance of Transactions printed from worn type on which corrections have been made, and differences in the make-up of The Journal and Transactions which have a bearing on the matter and which should be considered as well as the cost.

A year ago, on account of depressed business conditions resulting from the war in Europe, it was anticipated that there might be a reduction in the income in advertising which would necessitate curtailment in the production of The Journal. These fears, however, have proved to be groundless since the year has proved to be the most successful one for The Journal and the income which has been turned back into the publication for the benefit of the membership has been the largest in its history.

An appropriation has been asked for printing an index to the first 30 volumes of Transactions this coming winter.

The following is a statement of the budget for the past year and of the actual income and expenses:

STATEMENT OF THE BUDGET FOR THE PAST YEAR AND OF THE ACTUAL INCOME AND EXPENSES

Budget for 1914-15			Actual Income	Actual Expenses
	Income	Expenses		
Journal Text.....	\$21,000			\$20,133.38
Advertising.....	\$40,000	\$8,600	{ Cond. Cat. \$20,690.64 Journal \$24,675.48	{ Cond. Cat. \$7,705.28 Journal \$13,951.99
Transactions.....	11,000			11,844.12
Revises.....	500			278.00
Year Book.....	4,400			4,026.06
Total.....	\$40,000	\$55,000	\$44,766.62	\$59,038.83

REPORT OF THE RESEARCH COMMITTEE

I take pleasure in presenting the following report of the Research Committee of the Society for the year 1914-15.

The members of the Research Committee for the year have been as follows:

R. C. Carpenter, *Chairman*
R. H. Rice
R. D. Mershon
R. J. S. Piggott
A. M. Greene, Jr.

The Committee has held various meetings during the year, and has devoted a considerable amount of time to the promotion of various lines of investigation which have been referred to them, and has undertaken to stimulate further investigation by the appointment of sub-committees for special lines to work.

The Committee on Research was founded very largely as a result of efforts by the late C. W. Hunt, Past President of the Society. The first members were appointed by the late Col. E. D. Meier, Past President. The duty of the Committee as stated at the time of its appointment was to consist of work relating to the promotion of investigation, and of recording the results of investigation in the records of the Society where they would be useful for the engineering profession.

During the year the Committee has formulated concisely the field of work which it believes it should undertake, and in which there seems to be a demand for united effort, for the purpose of promoting investigations. As the result of careful consideration, the following statement as to the object of the Research Committee was agreed to unanimously:

The object of the Research Committee is to promote the investigation of phenomena, operations or results of experiments concerning fundamental laws on which engineering practice may be based, and to place such data in permanent and basic form.

For the purpose of promoting investigation it was decided some years ago to form sub-committees consisting of eminent specialists in the particular subject under consideration, and this duty has constituted the principal activity of the Committee.

The following sub-committees have been appointed and all report progress in the particular field which has been referred for their consideration:

SUB-COMMITTEE ON FUEL OIL

R. H. Danforth, *Chairman*
A. M. Hunt
L. E. Barrows
Ervin G. Bailey, resigned (accepted August 14); vacancy not filled

SUB-COMMITTEE ON MATERIALS OF ELECTRICAL ENGINEERING

R. D. Mershon, *Chairman*

SUB-COMMITTEE ON SAFETY VALVES

E. F. Miller, *Chairman*
P. G. Darling
H. D. Gordon
F. L. Pryor
F. M. White

SUB-COMMITTEE ON STEAM

R. H. Rice, *Chairman*
C. J. Bacon
E. J. Berg
W. D. Ennis

L. S. Marks
J. F. M. Patitz

SUB-COMMITTEE ON CLINKERING OF COAL

L. S. Marks, *Chairman*
F. C. Hubley
A. V. Bleiminger
O. P. Hood
O. W. Palmenberg
S. W. Parr

The appointment of other sub-committees is under consideration as follows:

Sub-Committee on an investigation of worm gearing. F. A. Halsey has taken a great amount of interest in this and has already done a large amount of commendable work. This investigation will require a considerable amount of time and quite a large investment in order to carry it through properly. It is believed that arrangements will be made for carrying out this investigation under the leadership of Mr. Halsey, who is willing to devote his personal time to the investigation without compensation. A sub-committee has been suggested, but it has seemed desirable to await further developments before making definite appointments.

Sub-Committee on Lubrication. The appointment of this sub-committee has been urged by a letter to the Council by F. zur Nedden, and several other prominent members of the Society. The Bureau of Standards, Washington, D. C., has expressed a willingness to carry out investigations along this line, and for that reason the Research Committee believes that a large amount of valuable data and practical useful information can be secured. A paper on this subject was read before the Society by M. D. Hersey of the Bureau of Standards, which points out many promising lines of research open to investigation. The Committee on Research will without doubt appoint a sub-committee on Lubrication to coöperate with the Bureau of Standards.

Sub-Committee on Research Relating to Machine Tools. This line of investigation was started some years ago by the National Machine Tool Builders Association in charge of a committee consisting of L. P. Alford, A. L. De Leeuw, J. B. King, E. R. Norris and Chas. Mills, and a considerable amount of money was expended in the building of a dynamometer. This association decided to abandon this line of technical investigation and recommended that the activity be transferred to The Am. Soc. M. E. Dr. Stratton, of the Bureau of Standards, has expressed a willingness and a desire to coöperate with The American Society of Mechanical Engineers in carrying out investigations along the line proposed by the technical committee relating to machine tools. It has been proposed to appoint as the sub-committee in charge of the machine tool investigation the members of the previous committee who are all connected with The American Society of Mechanical Engineers (which will include all excepting J. B. King) and to add to the committee some member of the Bureau of Standards in order to get the advantage of the laboratory connected with the Bureau and also the advice and assistance of Dr. Stratton and others. Secretary Rice has already corresponded with Director Stratton as to the field of work which the Bureau of Standards and The American Society of Mechanical Engineers can take up jointly with good chances of success.

Sub-Committee on Laboratory Equipment and Methods of Investigation. The appointment of a sub-committee which should consist of the directors and scientific investigators to

the college and other laboratories has been proposed and is under consideration by the Committee. It is expected that a sub-committee with membership as stated above would be able to bring about cooperation of the various laboratory plants of engineering colleges and would result in scientific arrangement of laboratory research and ensure to the Society the results of investigations possible with the equipment and staff of such laboratories. It has been suggested that a meeting for such a sub-committee be called at the time of the coming Annual Meeting in December.

The Sub-Committee on Safety Valves has been the means of obtaining several papers on this subject which have appeared in the Transactions of the Society. The investigations made by Prof. E. F. Miller are notably of great value, and have formed the basis for standardizing the safety valve practice and construction, which was formulated as a result of very extended consideration by the Boiler Code Committee jointly with the manufacturers of safety valves.

R. D. Mershon has been actively engaged in obtaining data as to the strength of electrical engineering materials and has succeeded in getting the cooperation of Prof. Orton and Prof. Boyd of the Ohio State University at Columbus. The result of this investigation is a paper by Professor Boyd, which will be read at the Annual Meeting of the Society. This is believed to give the first reliable results of the strength of ceramic materials and adds valuable data to the records of the Society.

Prof. L. S. Marks has undertaken the important work of determining the character and amount of waste in the combustion of coal which results in the production of clinkers. His sub-committee reports progress. During the coming year, I believe a considerable amount of useful data will be obtained which will serve as a basis of extended papers before the Society.

The Research Committee is hampered to a considerable extent by the fact that the fund available for promotion of investigation is small, and it has not been considered desirable to undertake any line of work, no matter how desirous or how promising, because of the need of financial backing, which was not, under present conditions, assured.

The Committee expresses confidence that at some time in the future funds may be available for the expense of promoting investigations and for making proper records and deductions from such investigations, which can be put in a condition available for the practical guidance of engineering construction.

Respectfully submitted,

ROLLA C. CARPENTER, *Chairman*.

REPORT OF PUBLIC RELATIONS COMMITTEE

The Standing Committee on Public Relations was first appointed about 1910, following the Washington Meeting at which the Constitution was amended to make provision therefor. It would appear that for the first few years after appointments were made no special action was taken by the Committee, although there were during this period some minor references made to it by the Council.

An appropriation of \$500 was made for the first time this year to cover the activities of the Committee. Following out the evident desires of the Society as shown by this Committee, a Public Service Session was planned and held in connection with the Annual Meeting in New York in 1914. This

session was addressed by his Honor the Mayor of New York, John Purroy Mitchell; by the then President of the Society, James Hartness, and by the President-elect, John A. Brashers, and by Andrew Carnegie. The following papers covering various parts of the field of Municipal Engineering were presented and ably discussed:

The Future of the Police Arm from an Engineering Standpoint, by Henry Bruere

Snow Removal, by Inter-city Committee on Snow Removal

The New Charter for St. Louis, by Edward Flad

The Engineer and Publicity, by C. E. Drayer

The Handling of Sewage Sludge, by George S. Webster

Some Factors in Municipal Engineering, by Morris L. Cooke

Training for City Employees in the Municipal Colleges of Germany, by Clyde Lyndon King

The Design and Operation of the Cleveland Municipal Electric Light Plant, by Frederick W. Ballard

A Study of Cleaning Filter Sands with no Opportunity for Bonus Payments, by Sanford E. Thompson.

The attendance at this session, the interest shown by the discussion and the demand there has been for the papers presented, all demonstrate that in carrying out this plan, a valued public service was rendered.

During the year a number of important references from the Council have been acted upon. The whole drift among engineers individually and as members of technical societies is toward a larger participation in public affairs. There are certain classes of activities that apparently fall clearly within our field and which we should undertake—activities which will be carried on by those poorly qualified to handle them if our profession fails to meet its opportunities. On the other hand, demands for our cooperation in increasing number will be made upon us that should be just as clearly declined. Without more experience than we have thus far had, it would be premature to make any hard and fast rules in this connection.

Among the subjects which have received favorable report of your Committee and which have later been endorsed by Council, are the participation by our Society in the activities of a joint inter-technical society committee to study the question of expert testimony and the methods under which it should be given. We also advised the appointment of delegates from our Society to serve on a joint committee made up of representatives from different engineering societies to assist the National Government in preparations for the engineering branch of a military reserve. The Committee under the able chairmanship of William Barelay Parsons has been in constant conference with the national authorities for months past. Delegates have also been appointed to serve on a board of engineers which made suggestions on engineering matters to the New York State Constitutional Convention.

It is believed by your Committee that if our Society can take up such lines of activity in fields obviously our own that we may develop methods of service of benefit to our Government—federal and state—as well as to the profession. To withhold such activity on narrow grounds would appear to be ill-advised.

MORRIS L. COOKE, *Chmn.*

COUNCIL NOTES

At the meeting of the Council on November 12, 1915, the following members were present: John A. Brashear, *President*, H. L. Gantt, R. M. Dixon, *Chairman*, *Finance Committee*, D. C. Jackson, A. M. Greene, Jr., Henry Hess, Spencer Miller, James E. Sague, Frederick R. Hutton, William H. Wiley, *Treasurer*, C. T. Main, E. E. Keller, and Calvin W. Rice, *Secretary*.

A special order of business was the consideration of the report of the Administration Committee. After an extended discussion, the Committee was invited to take into consideration the various suggestions of the members of the Council, and to frame recommendations in accordance with the views expressed.

The reports of the Standing Committees were presented and were ordered printed in this issue of The Journal and distributed at the Annual Meeting.

The appointment was announced of Ambrose Swasey as the representative of the Society at the Pan-American Scientific Congress and W. H. Marshall as alternate, in response to the invitation of the Department of State of the United States; and the announcement was made of the selection by the Secretary of State of Dr. John A. Brashear as the representative of the engineering profession in America to the Congress. E. M. Herr was appointed as the Society's representative at the celebration of Carnegie Day, November 23, commemorating the eightieth birthday of Mr. Carnegie.

Prof. Frederick R. Hutton presented a copy of the Society History, and announced the completion of its publication. A vote of thanks was tendered to him and to those who had assisted him in its preparation.

Interpretations of the Boiler Code were on motion received, ordered issued and published in The Journal.

The appointment of E. Howard Reed as Chairman of the Worcester Committee on Increase of Membership was confirmed.

It was voted to receive the report of the Committee on Threads for Fixtures and Fittings. This report will be printed and distributed and open for discussion at the business session, Wednesday morning, of the Annual Meeting.

It was voted to approve the exchange of house and library privileges with the Engineers' Club of Kansas City.

CALVIN W. RICE,
Secretary.

AN EMINENT PENNSYLVANIAN

[Editorial from The Pittsburgh Gazette]

In the proposal by a group of prominent Pittsburghers to honor the 75th birthday anniversary of John A. Brashear on November 24, there is exhibited a fitting sense of the long and valuable services of this truly eminent citizen of Pittsburgh and of the State of Pennsylvania. To be the chief guest at a banquet

is not an uncommon mark of distinction or of friendship, but in any effort, great or small, to honor Dr. Brashear, there will enter an element of universal approval that sets it apart from any like demonstration. As a scientist, as a citizen and as a brother to all men, John A. Brashear holds a peculiar place in the history of Pittsburgh and in the affection and esteem of his fellow citizens. His rise from obscurity to a place of authority and world-wide usefulness in the field of astronomical invention, and the story of his early struggles and patient endeavor to overcome the obstacles in his path, are parts of the history of Pittsburgh of which every man, woman and child, perhaps, has read and is proud.

His amiability, his thousand unheralded acts of philanthropy and his benign, cheery disposition are things that his more intimate friends know. He is "Uncle John" to hundreds of people still obscure in life and the simplicity and democracy of his association with his fellowmen have won him the deepest affection of old as well as young. To give John A. Brashear a banquet seems, in view of all that he is and has done for the world, a trivial compliment to a great man, but it carries with it the affectionate hope that the 75th anniversary of his birth may find him hale, happy and hearty and with many more ripe and peaceful years in which to enjoy the companionship of those who love him for the man he is and honor him for the service he has given to the city, the state and the world.

NAVAL CONSULTING BOARD

The second meeting of the civilian Naval Consulting Board took place in New York City on November 4, when the board was divided into sixteen Committees, each to deal with its own special problems. The names and personnel of these committees are as follows:

CHEMISTRY AND PHYSICS. W. R. Whitney, *Chairman*, Lawrence Addicks, L. H. Backeland, Joseph W. Richards, M. B. Sellers, A. G. Webster, R. S. Woodward.

AERONAUTICS, INCLUDING AERO MOTORS. Henry A. Wise Wood, *Chairman*, Howard E. Coffin, P. C. Hewitt, Andrew L. Riker, M. B. Sellers, E. A. Sperry, A. G. Webster.

INTERNAL COMBUSTION MOTORS. Andrew L. Riker, *Chairman*, Howard E. Coffin, M. B. Sellers, E. A. Sperry.

ELECTRICITY. Frank J. Sprague, *Chairman*, Lawrence Addicks, William Le Roy Emmet, P. C. Hewitt, B. G. Lamme, A. G. Webster.

MINES AND TORPEDOES. Elmer A. Sperry, *Chairman*, L. H. Backeland, M. R. Hutchison, Hudson Maxim.

SUBMARINES. William Le Roy Emmet, *Chairman*, A. M. Hunt, M. R. Hutchison, W. L. Saunders, Frank J. Sprague.

ORDNANCE AND EXPLOSIVES. Hudson Maxim, *Chairman*, L. H. Backeland, A. M. Hunt, M. R. Hutchison, Frank J. Sprague, A. G. Webster, W. R. Whitney, Henry A. Wise Wood, R. S. Woodward.

WIRELESS AND COMMUNICATIONS. P. C. Hewitt, *Chairman*, A. G. Webster, W. R. Whitney.

TRANSPORTATION. Benjamin B. Thayer, *Chairman*, Howard E. Coffin, Alfred Craven, Spencer Miller, A. L. Riker, Thomas Robins, W. L. Saunders, Henry A. Wise Wood.

PRODUCTION, ORGANIZATION, MANUFACTURE AND STANDARDIZATION. Howard E. Coffin, *Chairman*, Lawrence Addicks, William Le Roy Emmet, B. G. Lamme, Thomas Robins, W. L. Saunders, Benjamin B. Thayer.

SHIP CONSTRUCTION. Frank J. Sprague, *Chairman*, Spencer Miller, Joseph W. Richards, Henry A. Wise Wood.

STEAM ENGINEERING AND SHIP PROPULSION. Andrew M. Hunt, *Chairman*, William Le Roy Emmet, B. G. Lamme, Joseph W. Richards, M. B. Sellers.

LIFE SAVING APPLIANCES. Spencer Miller, *Chairman*, Hudson Maxim, Thomas Robins.

AIDS TO NAVIGATION. Elmer A. Sperry, *Chairman*, Alfred Craven, A. M. Hunt, Henry A. Wise Wood, R. S. Woodward.

FOOD AND SANITATION. L. H. Backeland, *Chairman*, Hudson Maxim, Benjamin B. Thayer, W. R. Whitney, R. S. Woodward.

PUBLIC WORKS, YARDS AND DOCKS. Alfred Craven, *Chairman*, Lawrence Addicks, A. M. Hunt, Spencer Miller, Joseph W. Richards.

Dr. M. R. Hutchison, Mem. Am. Soc. M. E., of Llewellyn Park, West Orange, N. J., has been appointed on the Board by Secretary Daniels. He is included above in the Committees on Submarines, Mines and Torpedoes, and Ordnance and Explosives.

INTERNATIONAL ENGINEERING CONGRESS

The volumes of Transactions of the International Engineering Congress, shortly to be issued, will be worthy of a place in the library of any member of the Society. Many of the papers are monumental, and the scope of practically each one is a review of recent signal work in the field to which it relates, as well as a discussion of the lines of future development. Collectively, the papers therefore represent the status of engineering in 1915. Many of them contain bibliographies of their subjects, which are invaluable for reference purposes.

The Committee of Management of the Congress reports that, on October 1, over 3,500 engineers and others had subscribed for volumes, and that subsequently 1,500 had ordered an average of 2.25 extra volumes each.

The Congress now extends an invitation to any who have not yet done so to subscribe to one or more of the volumes of Transactions of which there are eleven, as follows: The Panama Canal, Waterways and Irrigation, Municipal Engineering, Railway Engineering, Materials of Engineering Construction, Mechanical Engineering, Electrical Engineering and Hydroelectric Power Development, Mining Engineering, Metallurgy, Naval Architecture and Marine Engineering, Miscellaneous, including Aeronautics, Refrigeration, Agricultural Engineering, Engineering Education, Heating and Ventilation, Scientific Management.

Each volume is complete in itself and may be subscribed for separately, or a number of volumes or complete sets may be obtained. The contents of the volumes are substantially as given in the September number of *The Journal*, in which an advance program of the Congress was published. A subscription

form which may be used when ordering volumes is given in the advertising section of this issue.

The Congress was organized and conducted under the auspices of the American Society of Civil Engineers, American Institute of Mining Engineers, American Institute of Electrical Engineers, Society of Naval Architects and Marine Engineers, and this Society.

CONGRATULATIONS TO PHILADELPHIA

Philadelphia, always dominant in engineering, has now demonstrated that her engineers are supreme as engineers of men as well as of things. During five days of the past month, the members of the Engineers' Club of Philadelphia conducted a whirlwind campaign for new members. Starting with a membership of 551, it was expected that 1000 new members would be added. A corresponding reduction in dues was planned, based on a sliding scale in proportion to the number of members. Quoting from the Philadelphia Ledger:

The red paint that fills the immense thermometer in the Engineers' Club, marking the progress of the club's campaign for new members, who are to make Philadelphia the engineering center of the East, splashed over the thermometer's top yesterday, and the campaign, with 24 hours yet to go, was pronounced a huge success. In four days the club had recruited 990 new members, raising its total membership to 1541. Another record was broken in membership campaigns yesterday, when 331 technical men joined the organization. The campaigners were so enthused with their success that they set themselves a new goal. By noon to-day they expect the total of new members will reach 1250.

And this total was not only reached, but far exceeded. At the end of the five days 1672 members were added, making a grand total of 2,223. This is the largest membership of any Engineers' Club in the country, exceeding that of the Engineers' Club of New York by over 100, and resulting in a prospective reduction of dues from \$35 to \$15 per year. Many members of the local sections of the national societies are also members of the Engineers' Club, indicating the spirit of cooperation which exists. The sections represented include The American Society of Mechanical Engineers, the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Mining Engineers, the American Society of Illuminating Engineers, the local body of the Society of Automobile Engineers, and the local Technology Club of the Mass. Inst. of Technology.

INAUGURATION AT LAFAYETTE

Dr. John Henry MacCracken, former syndie and professor of politics, New York University, and an educator in philosophy, was inaugurated president of Lafayette College on October 19. The Society was represented at the exercises by William R. Dunn, Mem. Am. Soc. M. E., and two hundred colleges sent delegates.

The programme included a conference on Educa-

tional Problems of Lafayette College, an inaugural dinner, an academic procession and the conferring of nineteen honorary degrees.

REPRINT OF REPORT OF JOINT COMMITTEE ON STANDARDS FOR GRAPHIC PRESENTATION

Owing to the heavy demand for copies of the Report of the Joint Committee on Standards for Graphic Presentation, a second edition of the reprint of the Report as it appeared in the Journal of August, 1915, page VII, became necessary. As a result, the Report has been reprinted in the form of a 6 x 9 inch pamphlet of 8 pages, in which the illustrations have been remade to a uniform size and somewhat larger, to facilitate study of the diagrams and reproductions therefrom. The price of the pamphlet remains at 10c. per copy.

PROMULGATION OF THE BOILER CODE BY THE AMERICAN UNIFORM BOILER LAW SOCIETY

For the purpose of cooperative effort, leading to the introduction of the Boiler Code formulated by the Boiler Code Committee of the American Society of Mechanical Engineers early this year, an organization has recently been formed under the name of The American Uniform Boiler Law Society. This society, which has ambitious plans for extending its work into every state in the Union, is composed of representatives of all the industries connected in any way with steam boiler construction or operation. These industries and the men representing them are as follows:

Tubular Boilers.....	Thomas E. Durban
American Boiler Manufacturers Ass'n.....	E. R. Fish
National Ass'n of Thresher Manufacturers.....	H. P. Gooding
National Boiler & Radiator Manufacturers Ass'n.....	F. W. Herendeen
Low Pressure Steel Boiler Manufacturers.....	M. F. Moore
Water Tube Boiler Manufacturers.....	I. Harter, Jr.
Locomotive Manufacturers.....	John Wynne
Steam Shovel Manufacturers.....	Walter Plehn
Hoisting Engine Manufacturers.....	H. N. Covell
Boiler Insurance Companies.....	Chas. S. Blake
National Electric Light Ass'n.....	John Hunter
Boiler Materials.....	D. J. Champion

The above representatives form the administrative council of the Society, of which Thomas E. Durban has been appointed chairman. In order to defray the expenses incurred in the work of promulgation, an annual subscription, in varying amounts, has been made by the above industries through their representatives, amounting in total to \$12,000. It is proposed to expend at least this amount annually in the effort to secure uniformity of boiler laws throughout the United States and neighboring countries.

The council and chairman are anxious at all times to receive suggestions emanating from any source whatever, and are desirous of obtaining the moral support of everybody interested in the Code, as they feel that

this moral support is fully as important as is the financial support. They ask for earnest and sincere cooperation and advice.

In entering upon its activities, the Society held a meeting late in the summer, for organization and a proper division of the work and the voluminous business arranged for. The chairman, Mr. Durban, was authorized to personally visit the legislative representatives and industrial bodies in a number of states, and as a result considerable progress has been made during the early fall months. The chairman made a trip to the Pacific Coast, upon which he was able to meet with the executive committee of the Uniform Law Association in Salt Lake City, the Commission of Public Safety in California, the Commission of Labor in Oregon and the legislative representatives in Washington and Minnesota. Similar activities have been taken up in a large number of the remaining states by other members of the administrative council and definite progress in the matter of moulding public opinion is reported in both the lower Eastern tier of states and in New England.

The states that now recognize the Boiler Code of The American Society of Mechanical Engineers are Wisconsin, Indiana, Ohio, Pennsylvania and California, the last state having but recently established the Code under the authority of the Department of Public Safety. It is also to be noted that the Boiler Code of The Am. Soc. M. E. is in use as the standard code of the Boiler Inspection Department of the cities of Detroit and Chicago. Several other states are undertaking to adapt their boiler inspection departments to the requirements of the Code and some of the boiler insurance companies, notably the Hartford Steam Boiler Inspection and Insurance Company and the Fidelity & Casualty Co., have officially adopted the Boiler Code of The Am. Soc. M. E. as their standard for new boilers throughout all parts of the United States.

In important cooperative movement in the introduction of the Code in the legislative channels in the various states is the recognition given at a recent meeting by the National Electric Light Association, in the approval of the action of The American Uniform Boiler Law Society in its work. This association appointed Mr. John Hunter, member of the Council of The Am. Soc. M. E., as its representative to serve on the administrative council of The American Uniform Boiler Law Society, and it is expected that he will be particularly able in securing the cooperation of member companies in the various states.

An interesting indication of the universal applicability of the Boiler Code is to be seen in its adoption by representatives of the Argentine Republic, as specifications covering all orders recently placed in this country for boilers to be shipped to them. In the specifications of Direccion General Explotacion del Petroleo de Comodoro Rivadavia, 278 Balearre, Buenos Aires, S. A., the following is stipulated:

Each of the boilers under the items covered by Article I is to have a total heating surface to develop the rated horse power as indicated under Items for each boiler, based upon the evaporation of $34\frac{1}{2}$ lb. of water per h.p., at and from 212 deg. Fahr. Boilers will be built for a working pressure of 150 lb. per sq. in. and to general design and in strict conformity with the requirements of The American Society of Mechanical Engineers' Boiler Code, issued 1914.

Similarly, it has recently been reported that the Code has been made acceptable in the city of Manila, P. I., and efforts are being made to bring the matter of adoption of the Code in the entire Archipelago before the Philippine legislature which is soon to meet. The interests of the Code there are being promoted by Mr. Frank L. Strong, of Manila, P. I.

SECOND PAN-AMERICAN SCIENTIFIC CONGRESS

Announcement is made of the Second Pan-American Scientific Congress which will be held in Washington, D. C., December 27, 1915 to January 8, 1916. The headquarters of the meeting will be at the Pan-American Union in Washington, and it will be under the direction of John Barrett, LL.D., secretary general of the Union, and Glen Levin Swiggert, Ph.D., assistant secretary general.

The program of the Congress is divided into nine sections which, with the names of the Chairman in charge, are as follows:

- I. Anthropology, William H. Holmes, B.S., Smithsonian Institution, Washington, D. C.
- II. Astronomy, Meteorology, and Seismology, Robert S. Woodward, Ph.D., Carnegie Institution, Washington, D. C.
- III. Conservation of Natural Resources, Agriculture, Irrigation and Forestry, George M. Rommel, B.S., Bureau of Animal Industry, Department of Agriculture, Washington, D. C.
- IV. Education, P. P. Claxton, LL.D., Bureau of Education, Washington, D. C.
- V. Engineering, W. H. Bixby, Mem. Am. Soc. M. E., Brig. General U. S. A., Retired, Washington, D. C.
- VI. International Law, Public Law, and Jurisprudence, James Brown Scott, A.M., J.U.D., LL.D., Carnegie Endowment for International Peace, Washington, D. C.
- VII. Mining and Metallurgy, Economic Geology, and Applied Chemistry, Hennen Jennings, C.E., Washington, D. C.
- VIII. Public Health and Medical Science, William C. Gorgas, M.D., Sc.D., Surgeon General U. S. A., Washington, D. C.
- IX. Transportation, Commerce, Finance, and Taxation, L. S. Rowe, Ph.D., President, American Academy of Political and Social Science, Philadelphia, Pa.

Some of the Sections are divided further into Sub-Sections. There are forty-five of the latter in all, each with a special committee and program. The deliberations of the Congress will be based according to the subject-matter to be discussed in the various Sub-Sec-

tions. There will also be general sessions of the Congress as a whole. The various Sub-Sections of the Congress may arrange for joint sessions. There will also be joint sessions between certain Sections of the Congress and national Associations which may be meeting in Washington at the time of the Congress.

The following persons will be members of the Congress:

- a. The official delegates of the countries represented.
- b. The representatives of the universities, institutes, societies, and scientific bodies of the countries represented.
- c. Such persons in the countries participating in the Congress as may be invited by the Executive Committee, with the approval of the countries represented.
- d. All writers of papers.

Upon invitation from the Congress, Dr. John A. Brashear, President Am. Soc. M. E., and Ambrose Swasey, Past President Am. Soc. M. E., have been appointed as delegate and alternate, respectively, to the Congress.

The Committee of this Society coöperating with the Department of State in the conduct of the Congress consists of

GEN. W. H. BIXBY, *Chairman*,
 PROF. CARL C. THOMAS
 CHARLES T. PLUNKETT
 S. W. STRATTON
 CALVIN W. RICE, *Secretary*

All members interested are invited to communicate with the Secretary.

LOCAL SECTIONS CONFERENCE

One of the most important features of the Annual Meeting will be the series of conferences to be held by the Chairman and delegates from various local sections of the Society and delegates from various localities interested in the establishment of sections. The opening session of the conference will take place at noon Tuesday, December 7 and continue throughout the entire afternoon, enabling the delegates to give their individual attention to the matter. The Council has been invited to meet with the delegates at the opening conference in order to give opportunity for exchange of ideas with the representatives of Sections.

The Society considers this conference of great importance to its development and to ensure a full attendance of delegates arrangements have been made to pay the railroad fare of the chairman of each section to the meeting. The policy of the Society is to encourage the members of any locality where there are a sufficient number, to organize a section for conducting professional meetings and developing the Society there. Coöperation will be offered in such cases by granting an appropriation to cover the expenses of conducting

meetings, and assist in securing prominent speakers to address the members. Papers of value before sections will be published in full or in abstract in The Journal.

One fact which is emphasized is that in no case is the establishment of a section in a city where a local engineering society already exists an indication that the Society is entering into competition with that organization. Quite the contrary, the Society wishes in every instance to work hand in hand with the local Society or Club and hold joint meetings whenever possible. However, in practically all centers where local engineering organizations exist, there are a number of Am. Soc. M. E. members who are not members of the local society and therefore not enjoying the benefits of meetings and reunions, and it has been found by experience that the establishment of Sections of the Society in such places not only serves those who belong to the Am. Soc. M. E. only, but also strengthens the local organization and works to the mutual benefit of both groups and the community.

CONFERENCE OF STUDENT BRANCHES

The thirty-eight Student Branches of the Society have been invited to each send a delegate to attend a Conference of Student Branches to be held during the Annual Meeting. They will meet in the rooms of the Society Wednesday afternoon, December 8, from four to six o'clock, to discuss matters of importance in connection with the Student Branch work. The Committee on Student Branches, of which Professor F. R. Hutton is Chairman, will have charge of this meeting. It is expected to have ready for distribution a brochure setting forth the advantages of student membership and the reasons why every student of mechanical engineering should affiliate with the national society. It points out that the student obtains valuable experience in not only conducting meetings but in extemporaneous speaking and in the preparation and presentation of technical papers, and also in numerous other ways. This Conference will, it is hoped, have a stimulating effect on the development of Student Branch activities.

APPLICATIONS FOR MEMBERSHIP

TO BE VOTED FOR ON JANUARY 10, 1916.

Members are requested to scrutinize with care the following list of candidates who have filed applications for membership in the Society. These are sub-divided according to the grades for which their ages would qualify them and not with regard to professional qualifications, i. e., the ages of those under the first heading would place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, while those in the third class are qualified for Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to assume their share of the responsibility of receiving these candidates into Membership by advising the Secretary promptly of any one whose eligibility for membership is in any way questioned. All correspondence in regard to such matters is strictly confidential, and is solely for the good of the Society, which it is the duty of every member to promote. The candidates will be balloted upon by the Council unless objection is received by January 10, 1916.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

BARNHURST, HENRY G., Mech. Engr., Allentown, Pa.
Fuller Engrg. Co.,
BELLINGER, DANIEL L., Ch. Mech. Engr.,
Finch, Pruyt & Co., Glens Falls, N. Y.
BENT, STEDMAN,
With Phoenix Iron Wks. Co., Meadville, Pa.
CRAWFORD, CHAUNCEY H., Asst. Engr., Mech. Dept.,
Nashville, Chattanooga & St. Louis Rwy., Nashville, Tenn.

FLOWERS, ALAN E., Prof. of Elec. Engrg., Columbus, O.
Ohio State Univ.,
GILBERT, ERNEST M., Mech. Engr., New York
Wm. P. Bonbright & Co., Inc.,
GILLESPIE, WILLIAM K., Asst. Mech. Engr., Montreal, Canada
Canadian Steel Foundries Ltd.,
GUTHRIE, JAMES, Automobile Engr., Briscoe Jackson, Mich.
Freers,
JAY, EDWARD G., Jr., Engr. and Mgr. Meter Dept., Philadelphia, Pa.
Yarnall-Waring Co.,
KNOPP, GEORGE W., Asst. Mgr., Pottstown, Pa.
McClintic-Marshall Construction Co.,
McCoy, FRANCIS N., Master Meeh., Clark Mills, N. Y.
Hind & Harrison Plush Co.,
MANLY, CHARLES M., Vice-Pres. and Ch. Engr., New York
Manly Drive Co.,
MAXIM, HIRAM P., Pres., Hartford, Conn.
The Maxim Silencer Co.,
MEANS, EDWARD C., Mgr. Rwy. & Lighting and Pwr. Div., Westinghouse Elec. & Mfg. Co., Denver, Colo.
RUPERT, JUDSON W., Mgr., New York
Virginia Haloid Co.,
STEPHENSON, GEORGE F., Mgr. and Partner, Los Angeles, Cal.
Earl P. Cooper Co., Wis. Engines,
WOOD, HORATIO N., 1st Lieut. of Engrs.,
U. S. Coast Guard, U. S. Cutter "Apache," Baltimore, Md.

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

BUNGE, L. W. A., Mech. Engr., Chicago, Ill.
Armour & Co.,
CORDES, PAUL H., Chicago, Ill.
With Internatl. Steam Pump Co.,
DOWSON, HARRY R., La Salle, Ill.
Priv. Draftsman for F. W. Matthiessen,
GREENE, HARRY T., Designing Engr., New York
Aetna Explosives Co.,
McCLEARY, RAYMOND M., Industrial Engr., Brooklyn, N. Y.
Kirkman & Son,
STICHT, WILLIAM, Engrg. Dept., Elizabethport, N. J.
The Singer Mfg. Co.,

TURNER, ROBERT T., JR.,
With Foreign Dept., Niles-Bement-Pond Co., New York
WOOD, ROLAND T., in charge of Efficiency
Dept., The Standard Tool Co., Cleveland, O.
ZELLER, JAMES H., Prod. Engr., American
Bronze Co., Berwyn, Pa.

FOR CONSIDERATION AS JUNIOR

ADAMS, PORTER H., Preparing Pocket Book for Aeronautical
Engineers, Boston, Mass.
BACON, HOWARD E., Mech. Engr.,
Rochester Rwy. & Lt. Co., Rochester, N. Y.
BATTEN, LORING W., JR., Instr.,
Stevens Inst. of Tech., Hoboken, N. J.

MOTION STUDY FOR THE CRIPPLED SOLDIER

BY FRANK B. GILBRETH, PROVIDENCE, R. I.

Member of the Society

TO-DAY there are two million men living in Europe who have suffered the loss of limbs, faculties, or both, as a result of injuries in the great war. Before this war is over this number will be enormously increased. No one who has not actually seen hundreds of wounded soldiers writhing in agony in the cars or hospitals can fully realize the conditions that exist, but the pictures and accounts from the front have been so vivid that the whole world has been aroused to a concrete expression of sympathy and efforts to alleviate the immediate suffering.

However, there has been, as yet, little or no thought given to the permanent suffering that is by far the most serious aspect of the subject. What is to be done with these millions of cripples, when their injuries have been remedied as far as possible, and when they are obliged to become again a part of the working community? At the close of the war the various countries now engaged in it will find themselves for years, and probably decades, fully occupied in devising ways and means for paying the interest on their enormous debts. They will not be able to pension adequately and properly to provide financially for their astounding numbers of incapacitated soldiers. Neither would any system of pensioning, if that were financially possible, completely solve the problem, since the large majority of such cripples will be helped more by being provided with interest and occupation as well as financial support. The great problem that faces the world to-day is, therefore, immediate and permanent provision for enabling these millions of crippled soldiers to become self-supporting. This is a world problem rather than a problem for those countries only that are directly involved in the war, and demands a world-wide solution.

The crippled soldiers are of many types, for this war is a war of all classes, and not of the professional soldiers only, as one is at times inclined to think. In all countries, men from the colleges, the professions, the shops and the factories are at the front along with the usual military force. The cripples, therefore, will be of all types, and vary in training and capability as well as in the injuries that they receive. We might, therefore, roughly classify them as follows:

- a Men who have done chiefly mental work.
- b Men who have done chiefly physical work, but whose capabilities will allow them to be transferred to mental work.

c Men who have done physical work, and whose capabilities and inclinations are confined to physical work.

The first two classes can be handled with comparative ease when crippled. The third class presents the most difficult phase of the problem. This problem might be summarized as that of teaching and fitting cripples for some sort of productive work, and specially modifying and adapting the work to the individual capabilities, preferences, difficulties and shortcomings. The problem is an exaggerated new form of vocational guidance, vocational training, and systematic placement of men.

The educators have been quick to see their responsibilities in this work. They have provided, wherever possible, in existing or new institutions, opportunities for crippled brain workers to become productive, and have been ready and willing to devise opportunities and to furnish teaching for those previously engaged in physical work to learn and to use any mental work of which they are capable. They have, however, realized with equal rapidity their limitations in placing crippled soldiers whose bent is towards some type of physical work, as they have seen that this line of placement lies in the specialized field of the management engineer.

The engineer, both because of his training and practice, thinks largely in terms of physical capacity and its concrete results.

The engineer of to-day emphasizes the human element as a factor in accomplishing results, and it is his peculiar province to make this human element most efficient. Knowing that the author had specialized for years in this type of work, educators in the various warring countries have urged him to attack this particular branch of the crippled soldiers' problem, and to put the results of modern management in general, and of motion study in particular, at the disposal of those in active charge of training the cripples. No great amount of urging was needed. The author has, since the war began, crossed more than a dozen European frontiers. He has visited many hospitals and recovery homes, and seen at first hand the frightful need, and he returns to this country not only with the desire to be of service, but with a definite plan as to how service can be most adequately rendered.

The method of attack of the problem is as follows: It is realized that the psychological feature is an important one. A prime necessity is to inspire the cripple with the feeling that he can remain, or become, a productive member of the community. This is done by gathering data as to cripples of various types who have succeeded in becoming useful and earning members of the community. These data consist of

concrete examples of men, women, or children incapacitated in any way, who have been enabled by any possible means to be useful to themselves and to society. Such data have been and are being accumulated at an astonishing rate. They serve not only to encourage the cripple by suggesting that what has been done, can be done, but also by indicating immediate methods of attack upon individual problems. Back of all these individual illustrations, however, must lie a scientific method for attacking the general and the individual condition of each cripple, for diagnosing the particular case, and prescribing an adequate remedy. This is our contribution towards the solution of the problem.

The motion study method of attack considers the work to be done as a *demand* for certain motions, and the proposed worker as a *supply* of certain motions. It aims

self-supporting and interested. That he become and remain interested implies the highest form of teaching and of learning.

The first step in adequate placement through motion study lies in visualizing the motions used, or necessary, in any given type of work. The simultaneous cycle motion chart is a device for recording and showing the interrelation of the individual motions and cycles of motions used in any method of performing any piece of work. This motion chart was devised and is used by us in our consulting work of motion study in the industries. Here we deal mostly with those who have the use of all their limbs and faculties, but the chart is equally applicable when dealing with cripples.

The elements of a cycle of decisions and motions, either running partly or wholly concurrently with other elements in the same or other cycles, consist of the following, arranged in varying sequences: 1. Search, 2. Find, 3. Select, 4. Grasp, 5. Position, 6. Assemble, 7. Use, 8. Dissemble, or

FIG. 2 ATTACHMENT OF ELECTRIC BULBS TO HANDS OF SURGEON FOR MAKING CHRONOCYCLEGRAPH OF SURGICAL OPERATION

FIG. 3 CHRONOCYCLEGRAPH OF A COMPOSITOR PUTTING TYPE IN A STICK

a To consider all work from the motion study standpoint,—to discover exactly,

- 1 What motions *have* been used for the work.
- 2 What motions *may* be used for the work.
- 3 What motions *must* be used for the work.

b To discover what motions are possible to the proposed worker.

c To determine which type of work may best be adapted to the worker, and how.

It may be well to state that motion study considers always three groups of variables, which, in the industries, are

- a The variables of the worker.
- b The variables of the surroundings, equipment and tools.
- c The variables of the motions.

In adapting motion study to the crippled soldiers' problem, we are considering these same three groups.

We realize that our problem is twofold in its aspect. It consists of

- a Determining the type of work that the particular worker can best do.
- b Determining that method by which he can best be taught to do the work.

The teaching element is more important in this new phase of adequate placement than it has ever been before, because—
—case a new or changed worker must be made useful,

take apart, 9. Inspect, 10. Transport, loaded, 11. Pre-position for next operation, 12. Release load, 13. Transport, empty, 14. Wait (unavoidable delay), 15. Wait (avoidable delay), 16. Rest (for overcoming fatigue).

The simultaneous cycle motion chart is best made on decimal cross-sectioned paper. The horizontal lines, reading from the top down, represent time. We have found that the thousandth of a minute is the best unit with which to work. The various vertical spaces are divided into anatomical groups, such as right arm and left arm, consisting of the subgroups, upper arm, lower arm, wrist, thumb, first finger, second finger, third, fourth, and palm; right leg and left leg, with the subgroups of thigh, knee, calf, ankle, heel and toes; trunk, with the subgroups of forward bend, backward bend, bend to right, bend to left, twist to right, twist to left, hump, and shrug; head, with the subgroups of forward bend, backward bend, turn to the right, turn to the left, and mouth; eyes, with the subgroups of ball, pupil and lens. There should also be the general heading of *inspection*, with the subdivisions of see, smell, touch, taste, hear, blow, and count; and the heading *posture* with the subdivisions of sit, stand, kneel, stoop, right forearm supported, left forearm supported, right hand supported, left hand supported, back supported and head supported, etc.

Charting the data in this manner makes it possible at a

glance to visualize a simultaneous cycle and the elements of the cycle of work done. The various motion cycles in the method under investigation are analyzed into these elements. Through this analysis we are able to work out new sequences, cycles and methods of doing any type of work. Thus many types of work that have been formerly considered possible only for the man in complete possession of all his members and faculties can be adapted to the maimed or crippled worker. The chart shows in a concrete form which members and faculties of the associated units or working members of the human body are doing the work, are inefficiently occupied, or are available for doing parts or all of the work. They enable us to see at a glance not only how motions are at the present being made, but the possibilities of shifting these motions to other members of the worker's body. In

FIG. 4 CHRONOCYCLOGRAPH OF THE TWO HANDS OF A GIRL FOLDING HANDKERCHIEFS

other words, when using these charts for the crippled soldiers' work we are enabled to proceed immediately and directly to the more efficient rearrangement, distribution and assignment of the necessary motions to the different remaining members.

The data included in these charts are gathered through various methods of making motion studies, especially by the use of the micromotion method and the chronocyclograph method of recording motion in the research laboratory. Here records of methods are made with the special devices, micro-chronometer and the cinematograph, and also with the chronocyclograph apparatus. The former type of records record the activity of the worker, the surroundings, equipment and tools, and also the time of the motions used. The latter records show the directions, speeds and paths of the motions. The records serve not only as data for the simultaneous cycle motion chart, but also as the most efficient of teaching devices. From the chronocyclograph records are made motion models that not only make it possible for teacher and learner to visualize the desired motions from all viewpoints, but that also serve as path guides in case the worker taught is of the motor type.

Until recently, it has been considered good enough practice in the industries to teach the traditional or existing method of a successful workman. Through the methods and

measuring devices of precision used in the motion study laboratory we are now able to record with exactness and in detail the methods of the most skilled workmen. By the use of the scientific method of analysis, measurement and synthesis we arrive at the method of least waste for performing the work. Through special teaching devices we then transfer the selected elements of skill and experience, in a new synthesized cycle of least waste, to workers who have never had that all around, non-guided experience or its slowly acquired skill. Not only are the methods transferred more efficiently but there is saving of time and effort to both teacher and learner, as is satisfactorily shown by learning curves of many past performances on widely varied types of work. The teaching devices, which we have specially adapted to appeal to as many types of workers as possible and to all available senses, are especially useful with crippled learners, where it is often necessary to specialize on some particular sense training.

The fatigue study that accompanies the motion study provides for the elimination of all unnecessary fatigue, and for adequate rest for overcoming necessary fatigue. Such study is imperative in the work with cripples, since the greatest of care must be taken that the maimed worker is not over-taxed.¹

While this method of attack is bringing gratifying results, no great headway can be made with the crippled soldiers'

FIG. 5 DIAGRAM OF THE MOTIONS OF A GIRL FOLDING HANDKERCHIEFS AND A WIRE MODEL MADE FROM IT

problem without worldwide cooperation. Such cooperation has been forthcoming wherever interest in the subject has been aroused. We gratefully acknowledge the receipt of suggestions and cooperation from members of our organization, from friends in many parts of America and other countries, and particularly from the alumni and friends of our Summer School of Scientific Management, and we most earnestly beg for more and more. We need photographs, records and histories of cases where cripples have been made comfortable and less fatigued in their work, and have been taught and are successfully doing work in spite of their apparently insurmountable handicaps. The crippling is of every conceivable type, and every success will encourage some disheartened invalid to take up life with a new courage. We want also suggestions for adaptations of machines, tools, and other equipment or surroundings to workers. For example, we have found that typewriter manufacturers have made attachments for the use of operators having one hand only. We have seen such an operator handle the modified machine with satisfactory results. We have found that slight modification of other machines permits assigning their operating and controlling parts to the remaining limbs of the workers, and thus makes possible their successful handling by injured operators. Any kind of an adjustment

¹ See "Fatigue Study," Sturgis and Walton.

or adaptation may be not only useful in its particular field, but may also form a missing link in an invention in an entirely different field. We will gladly take all data sent us and make them immediately useful to those working on the training of the injured soldiers in all countries. We have found it most efficient to think of all activity in terms of motions and decisions. Through more than thirty years of work in motion study we have facilities that make it possible to analyze all data into terms of motion economy, and thus to make them useful with the least waste in transmission or handling time.

This work of helping the crippled soldiers by teaching them to make the most of their motion possibilities should be the special contribution of the engineer in the field of social betterment. The opportunities for such work to-day are especially large because of the great war, but the methods that we now advise and use because of the great pressure will be available at all times. Through the reclamation service, if we may so call it, that we are using for the war cripples to-day, we are introducing a method that will never become unavailable or unnecessary.

We beg every member of the American Society of Mechanical Engineers to coöperate in this work, with us and with our friends abroad, who are waiting to pass on the data to those who need it so sorely. It is a work that is both timely and permanent. The need is sudden and new, but the data will be useful forever.

DISCUSSION

L. M. WALLACE (written): It is indeed gratifying that such an able investigator as Mr. Gilbreth has consented to devote time and effort toward solving the problem of providing for the instruction of those disabled by the European war. That large numbers of young men of the highest type are being crippled for life is indeed as distressing as that so many are losing their lives in this great world calamity. It is my conviction that it is just as noble an undertaking to attempt to provide suitable means of preparing the disabled for useful vocations as it is to attempt to stop the terrible conflict or to provide means of first aid. Indeed, it is a greater thing than many realize, because it will mean untold benefit to thousands now deprived of those avenues of activity to which they have been accustomed. It will mean the fitting for useful vocations of thousands, who otherwise would be dependents upon society, which is always a greater burden to the one so afflicted than to those of society who bear the expense of such disability. I therefore hope Mr. Gilbreth and his associates may achieve much and that the members of this Society will rally to his support by extending encouragement, helpful suggestions and material assistance in the form of thought, labor, and money, if desired.

EDWARD VAN WINKLE: There is no question but what the adoption of a machine to a crippled soldier or a man without arms or legs is the duty of the mechanical engineer. I remember seeing the driver of a speed car, a man without arms, travel over a hundred miles an hour in a machine especially designed for him. The steering gear of the machine was adapted with shoulder yokes and the rest of the apparatus was operated by his feet. I saw him go from high speed forward to high speed backward inside of 50 ft.,

and he had a record of 108 miles an hour. There is no doubt that there are a number of instances of that kind in which with special machines cripples have been enabled to emulate those with full faculties.

W. HERMAN GREEL inquired whether Mr. Gilbreth had outlined any standard method of reporting these instances

FIG. 6. EXAMPLES OF APPLICATION OF CINEMATOGRAPH TO MOTION STUDIES OF WORKMEN

which he could use in his tabulations. He wondered whether he had already tabulated the information which he desired, which would be very helpful in aiding the members to contribute.

DR. YEAGER, in his discussion, said, as a physician, he had been interested in cripples for a good many years, and in the course of his work he saw the necessity for providing

means of occupation for many of these cripples. Some three years ago he opened a school for the training of men who had been maimed or injured or who, through some disease, were incapacitated from active work. In this school as patients were men sixteen up to thirty-five, who were taught reed work of all kinds, reed furniture making, rush seating and basket making. To the men who have the use of one and one-half hands, and whose minds are sufficiently developed, mechanical drawing is taught. For the men with one hand only, we selected glass mosaic work; a plan was devised for holding the glass so that with the one hand the worker could take his glass cutter, cut the piece of glass and fit it into the pattern he was making. We have taught show card writing, and also silversmithing.

As you will notice, most of these trades are for men who have the use of two good hands. Reed work needs two good hands. An encouraging feature of this work is that men

unseemly fashion, learned the trade of chair caning, and during the summer vacation he managed to get the contract for a large club which needed several hundred chairs, and this cripple engaged ten able bodied men to work for him.

A boy with a very bad deformity of the hip needed two crutches to go about the workshop, but notwithstanding this he was able to work very well.

The work at this school is being done in the City of New York. It is the only school of its kind in the country, and whereas we have not attempted to get the men into work where machinery is required, we feel that we are filling a definite place in the work that we have done.

MR. HANAU: When radium was discovered it was thought to be good for anything, for everything, for tuberculosis, for cancer, and for almost everything. The same remark applies to moving pictures. If you consider the moving

FIG. 7. CYCLOGRAPH OF A MAN OPERATING A MACHINE WITH WHICH HE IS NOT FAMILIAR

FIG. 8. CHARACTERISTIC ORBIT OF THE SAME MAN AFTER MAKING A HALF DOZEN PIECES ON THE MACHINE

FIG. 9. CYCLOGRAPH OF SAME MACHINE AFTER IMPROVEMENTS MADE TO FACILITATE HANDLING OF MATERIAL

who had never done any of this kind of work before, men who had never done any skilled work with their hands at all, would, in the very shortest space of time, become expert. I remember one young man, a structural iron worker, had an injury in which he lost one leg. He had no other trade, but he came to the school and became an expert silversmith; he did very beautiful work. He developed into a very fine draftsman, although he had no home training. He was a man from the very lowest circles, but the surroundings, the beautiful designs that we gave him, developed in him a desire for creating beautiful things, and he became a very skilled craftsman.

Another case was that of a young man who was born with his hands in an abnormal position, rendering them practically useless. We taught him show card writing. He held his pen in his left hand, and he was able to draw and make letters very well. Another young man, whose right hand was paralyzed, just had sufficient power to hold his paper and pen, to do mechanical drawing.

A man who had paralysis in both legs, and who needed two crutches, as both his legs dangled under him in a very

picture, however, you must always keep in mind that it is a perspective. In the second place, you must keep in mind that the movements are not all in plane, so that they are very deceiving. To represent the three dimensions by photographs, you have to take them from the three sides, that is, the front, side and back projections. Then you can combine a movement which will be followed up very accurately. While this method is very good for efficiency, I do not think it is of very much value for just the purpose of this paper.

In working out data for members and other parts of the body for crippled soldiers, or maimed persons, one must be very careful. Such data cannot be represented only by a perspective picture, although perspective pictures are very valuable in shop practice.

F. ZIE NEDDEM: A few weeks ago Mr. Gilbreth showed me a novel improvement of his method, giving the means for taking motion studies in the tri-dimensional way. For this purpose, Mr. Gilbreth first photographs a tri-dimensional net of white lights, he then removes the net, places the workman in position, and makes motion studies. By this

way he can conceive, especially if he makes photographs stereoptically, exactly the place every motion in space occurs. This would meet the objection raised by Mr. Hanau.

H. E. RESSELER gave an instance of a mechanical device made recently in one of our hospitals in New York City. A young girl had a form of tetanus and by removing the muscles of the lower jawbone, and making a device with a spring, to be wound up just like one would wind up a clock, fastening it to the jaw and running it over the head, the jaw was kept in constant motion. After about three weeks the device was taken off. It was surprising to note how the muscles of the inferior maxillary had developed. The girl was then put to chewing gum, and the development of the muscles of the lower jawbone was continued.

JAMES GIBBONS: The work proposed to be carried out in Europe with a view to aiding crippled soldiers should hold a very important lesson for us in this country, because it seems it is an attempt to approach the efficiency question from another point of view than that which we are accustomed to. There is a tendency I think on the part of the efficiency engineer to pay more attention to the man of efficiency and to a certain extent discard the less efficient man, and a good deal of the opposition to efficiency methods which no doubt exists in the minds of many, and especially of workmen, is due to the feeling that the men naturally less efficient will be sacrificed to a great extent to those more efficient.

The fortunes of Europe are forcing upon men the necessity of taking care of their less efficient fellows.

From the point of view of the working public and from the point of the good of the country as a whole, this is perhaps the real foundation on which we should build on efficiency efforts—from the bottom up rather than from the top down; and I think we would be making a great mistake if with our own prosperity and our own good fortune in this country we should not give our careful attention to what is being done in Europe and watch carefully for the results which will come from this effort to raise the efficiency of those who are naturally inefficient.

W. N. POLAKOW: The paper by Mr. Gilbreth is of great importance, not only for the European problem of the near future, but for that in the United States, which is, so to speak, permanent, because industrial accidents happen and will happen in this country, although probably in diminishing proportion. It is well known to us how much money is being paid to the crippled soldiers of former wars, although if provision of some kind had been made in this country they could have been put to productive work and not be a burden on the country, but be productive members of society; but aside from that there was a question raised here whether it is in the domain of an engineer to look into this matter. In my opinion, it is most emphatically so, and I think we all owe Mr. Gilbreth thanks that he raised this question in our own Society.

The case of the crippled soldier is nothing but using the triple expansion human body as a compound, or something less than that, as it were, and therefore it is a problem of engineering, and of the works manager to adapt these conditions, or the men to the conditions, so that they will be useful. It is not so much the question of the selection of the man for the particular work, as the adaptation of the avail-

able man to the work which is to be done, whether the man is crippled or not.

As to the instruments devised by Mr. Gilbreth, I have watched and studied them in actual use, in the New England Butt Co.'s laboratory, although the details were too complicated to be explained in a short talk. The point of importance is that the motion shall be studied in order to save the waste motions and find out in what industrial processes certain limbs and certain parts of the body, certain muscles, are used.

In a factory where wearing apparel is sewn, the legs are absolutely unnecessary, as the machines are driven by a motor. In many other industries, when we consider it necessary to employ able-bodied men, we are doing a great injustice to those who are crippled, and more than that, we manifest our own lack of understanding. We do not want legs for the man who is working with his brains, and vice versa for the messenger boy it is not necessary for him to have two hands. For a telegraph operator two arms or two hands are entirely unnecessary, and many other examples could be cited.

ALVIN LOUIS SCHALLER: I think that one of the points ought to be emphasized that Mr. Gilbreth brought out in his paper, and that is the psychic state in which the man must be brought before he can be made successful. The only reason why a cripple is so successful is because he has a will and a determination to devise his own methods for doing things.

I believe that one of the largest problems that Mr. Gilbreth had to confront when he began to reclaim these crippled soldiers was to get them into a state of mind where they could forget the discouragements into which they had probably fallen after receiving their wounds and realizing that they would have to go through life in a crippled condition.

ROBERT THURSTON KENT, who presented the paper, said: Last August I spent a day at Mr. Gilbreth's laboratory and saw what he had developed in the four years since I was associated with him, and Mr. Gilbreth converted me to a number of things that I believed were absolutely impossible two or three years ago, and I would suggest that all who are skeptical as to the value of the moving pictures of stereoscopic photographs and the three dimensions visit Mr. Gilbreth's laboratory, where they will learn a great deal.

The problem of efficiency or scientific management is to point out the job at which a man is a first-class man and put him in it.

Mr. Gilbreth has a standard method of tabulating. He lays out a chart divided into different groups, as explained in his paper—the head group, the different arm groups, etc., subdividing them into the forearm, the hand, thumb, and so on. By means of his photographs he finds out the relevant amount of time each member of the body is employed on a given job; he plots them on a vertical scale as to time. Striking a curve through these ordinates, he can see the relative importance of each particular member of the body in doing certain work.

The particular method employed is to take these charts and see if these motions of all the parts cannot be eliminated altogether, so that in the case of only a right hand motion, the motion of the left hand is gotten rid of, making it all a job on which the right hand only is employed.

GAS VOLUME AND DUST CONCENTRATION DETERMINATION IN CONNECTION WITH THE COTTRELL PROCESS

WM. N. DREW, LOS ANGELES, CAL.

Member of the Society

It is evident that, for general engineering work, any apparatus for determining the velocity of the gases in the conduits of a plant to which a Cottrell treater is to be applied must be portable, accurate, simple in construction, and easily and readily manipulated. Anemometers are unreliable in a fluctuating flow, otherwise they comply with all the above requirements; they are necessarily somewhat delicate, and in hot, dusty gases their mechanism may be seri-

d_s = weight per cu. ft. of air at 32 deg. Fahr. and 14.7 lb. = 0.08073 lb.
 g = acceleration due to gravity, taken as 32.16

$$V = \sqrt{h_i}$$

$$= \sqrt{\frac{2gbd_w}{12d}}$$

since $d_{li} = \frac{hd_w}{12}$ and $d = d_s G \frac{P}{14.7} \times \frac{491.2}{T}$

hence $V = 11.12 \sqrt{\frac{hT}{PG}} \dots \dots \dots (1)$

$$= 15.88 \sqrt{\frac{hT}{BG}} \dots \dots \dots (2)$$

$$= 21.30 \sqrt{\frac{hK}{BG}} \dots \dots \dots (3)$$

For air $G=1$ and at atmospheric pressure $B=29.92$, so (3) becomes

$$V = 3.894 \sqrt{hK} \dots \dots \dots (4)$$

Within the errors of observation, these formulae are accurate for dry air up to 100 ft. per sec., but at 183 ft. per sec. they give results 6 per cent too high and at 383 ft. per sec. 15 per cent too high.

FIG. 1 TYPE OF PITOT TUBE USED

ously deranged. Venturi tubes are easily manipulated and very accurate, but are not portable. The Thomas electric meter is extremely accurate, but it also is not portable.

The Pitot tube is the last choice and fulfills very completely all the stated requirements, while in addition it is inexpensive and easily constructed. This instrument is a well-known one, and tests of particular types have been the subject of extensive investigations. It is estimated that, with the type of Pitot tube illustrated in Fig. 1, which is the standard testing tube of the American Blower Company, and with accurate gages, it is possible to obtain an accuracy of within 1 per cent. However, even with an absolutely accurate tube, uncontrollable conditions in the gas flow may vary results a like amount.

The Pitot tube follows the law of falling bodies, and a working formula based on this may be derived as follows:

where

- T = absolute temperature of flowing gas in deg. Fahr.
- K = absolute temperature of flowing gas in deg. cent.
- P = absolute pressure of flowing gas in lb. per sq. in.
- B = absolute pressure of flowing gas in inches of mercury
- d = weight per cu. ft. of flowing gas at a given temperature and pressure
- G = specific gravity of flowing gas (air = 1.0)
- V = actual velocity of flowing gas in ft. per sec.
- h_i = height in ft. of a homogeneous column of gas at given temperature and pressure producing V
- h = corresponding height of water column in in.
- d_w = weight per cu. ft. of water = 62.37 lb. at 60 deg. Fahr.

FIG. 2 PARABOLIC FORM OF CURVE EXPRESSING THE VELOCITY IN CROSS-SECTION OF CONDUIT

The location of the Pitot tube in the conduit is a matter of considerable importance, especially as it is usually desired to obtain the average velocity for a given cross section. The law governing the variation of velocity from center to side of a conduit has not been definitely established, and, moreover, the determination of the velocity contour is difficult owing to errors of observation, abnormalities of flow and to the impossibility of making a measurement at the extreme edge of the pipe.

If we assume that the curve expressing the velocity at a cross section is a parabola with its vertex at the axis of the pipe, we may deduce a relation between the center velocity V_s and the mean velocity V_m in a cylindrical conduit of circular cross section as shown in Fig. 2. From this diagram it may be seen that the amount of fluid passing the section each second is represented by the solid generated by rotating the figure $acdeb$ about fd as an axis. The volume of this may be divided into two parts, one a cylinder $acrb$ and the other a paraboloid cde . The volume of the cylinder is $\pi r^2 V_s$, and of the paraboloid $\frac{1}{2} \pi r^2 (V_e - V_s)$. If we divide the total volume of the solid by the area of the pipe we obtain $V_m = \frac{2 \pi r^2 V_s + \frac{1}{2} \pi r^2 (V_e - V_s)}{2 \pi r^2} = \frac{V_s + \frac{1}{2} V_e}{2}$

If we assume that the surface velocity is one half that at the center, we may write $V_m = 0.75 V_s$.

Similarly on the assumption that the contour is repre-

sented by an ellipse, since the volume of an ellipsoid is two-thirds that of the circumscribed cylinder, we may write

$$V_m = \frac{3 \pi r^2 V_s + 2 \pi r^2 (V_s - V_c)}{3 \pi r^2} \quad \text{and on}$$

assumption that $V_c = 2V_s$, $V_m = 0.83 V_s$.

Although it is apparent that an approximate relation exists between the mean and maximum velocities in a conduit of circular section, too much dependence must not be placed on this ratio. Loeb (*Journal A. S. Nav. Eng.*, vol. 24, p. 1115, 1912) states that a single Pitot tube at the center of a circular duct will have a coefficient of mean velocity of 0.91 to 0.94, depending on the size of the duct and the velocity of the air. For a 12 in. galvanized iron pipe, Rowse found that results within 2 per cent may be obtained by using the ratio 0.895.

This regular flow is disturbed by expansion, contraction, or curvature of the conduit, and more especially by obstruc-

tion in the particular cross section selected. In a circular duct, the cross section may be divided into a number of annular rings each having the same area, and then, by taking readings at equal intervals around these rings, velocity readings can be obtained and readily averaged. In averaging these readings, the mean of their square roots must be used rather than their direct arithmetical mean.

Traverses in a pipe along one diameter only are not sufficient, as readings on vertical and horizontal diameters are rarely the same, except at the points nearest the center. For a conduit of any section, a more accurate method is to make these traverses along several diameters, and then, after making a contour for each diameter, combine these into one which will show the contour for the entire cross section. Fig. 3 shows a contour obtained in this way. Twelve readings were made on each of the four diameters by a movable Pitot tube, another Pitot tube being kept fixed in position

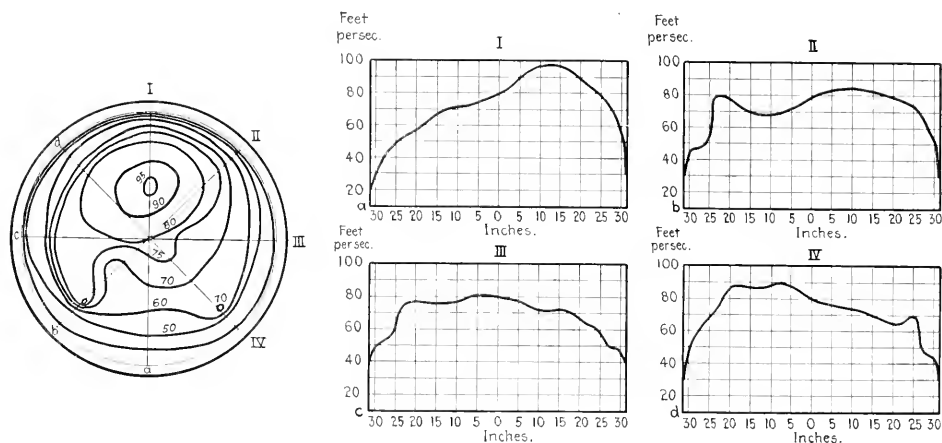

FIG. 3. RESULTS FROM TRAVERSE READINGS WITH MOVABLE PITOT TUBE ACROSS DIFFERENT DIAMETERS OF CONDUIT

tions. It is probable that in a gas stream, as in a water stream, the static pressure after expansion or contraction will be higher than the normal, and that after a curve the indications of pressure on the concave side will be high and on the convex side low. Rowse found that gas flowed through a pipe with a wave or spiral motion even when many screens were inserted to straighten out the stream lines. Curves obtained by traversing the cross section of pipes with the Pitot tube show more or less uniformity.

Rowse states that in gas measurements a Pitot tube station should be preceded by a length of pipe 20 to 38 times the pipe diameter. Fan discharge into a pipe line disturbs the flow somewhat, but Trent (*Trans. A.S.M.E.*, vol. 34, p. 1019, 1912) states that good Pitot tube measurements can be taken 8 to 12 diameters away from the fan.

Since there are so many unknown conditions in a conduit conveying gases, it is evident that the most reliable results will be obtained by making a large number of measurements

at the center of the cross section and readings being taken simultaneously with the movable tube. The velocity readings obtained with the fixed tube were averaged and this velocity used as a base from which to correct the velocities obtained with the movable tube, since all the velocities in the cross section are continually varying; it was assumed that the other velocities varied according to the ratio between the average center velocity and the "instantaneous" center velocity, and this ratio was applied as a correction. With a planimeter, the area shown on the final contour plot corresponding to each velocity was measured, and from this a weighted mean was calculated for the entire cross section. In this particular case the mean velocity was 64 ft. per sec.; and it is interesting to note that the region of maximum velocity was not at the center. The cross section shown is in a stack carrying gases from a cement kiln, and is 100 ft., or about 20 diameters, from the mouth of the kiln. In the stack base, the kiln gases are first deflected downwards by a

curtain wall, and on resuming their general upward travel their motion acquires a horizontal component in "reaching out" for the stack entrance, and the gas volume "hugs" the stack all the way to the cross-section shown.

After several such determinations as this, a ratio between the mean velocity and the velocity at any other point can be determined; and by using this ratio one measurement will indicate the total gas volume. In choosing such a point, it is obvious that the location should be such that no rapid

Aside from the question of the amount of the escaping material, it is desirable to know its composition, so that the percentage loss of valuable material may be calculated. In order that all these questions may be determined, it is necessary to remove some of the gas with its accompanying dust. The ideal way to do this would be to entrap a known volume of the dust-laden gas, weigh and analyze the solid matter carried by it, and from these data calculate the ratio desired.

Fig. 4 shows diagrammatically an apparatus which is used in an attempt to approximate this ideal method. *A* is a conduit through which the gases and dust are passing. In this conduit is placed a tube *B*, with its mouth pointing toward the flow of the gases, and, at the other end of this tube, suction is applied to draw through some of the gas with its accompanying dust.

As the gas passes through the pipe it reaches the filter *F*, which retains the solid matter but allows the gas to pass. This filter consists essentially of two parts, a Soxhlet fat extraction thimble, and a holder of brass hollowed to receive the thimble. The essential features of this holder are a tight fit at the mouth when the knurled nut is screwed home, and a good clearance, say about $\frac{1}{8}$ in., around all sides of the thimble. The reason for this first essential is obvious, for leakage must be prevented, while the second one is indicated by experience, tests having shown that the filter quickly clogs if there is only a slight space between the thimble and the holder.

In order that a fair sample of the gas and dust may be obtained, the suction applied should be such that the velocity at the mouth of tube is the same as the velocity in the stack, for, if it is greater, more dust is drawn through in a given time than should be, and vice versa. To adjust the velocity in *B*, two static tubes are used, one of which, *C*, is a closed tube with small holes near its tip, the other is a tube drawn down to a small hole and opening to the inside surface of *B* near its mouth. The other ends of these tubes are connected to a balancing gauge, *G*, and the suction adjusted so that the column is always in balance.

After suction has been applied for a known length of time the filter is removed, dried, and weighed; then from the amount of dust in the filter, the time of aspiration, and the ratio of the area of *B* to the area of the conduit, the amount of dust passing through the conduit *A* in a unit of time is calculated.

An important feature of the operation of this and other apparatus using a filter is the proper previous and subsequent drying of the filter thimble. The amount of dust caught is usually so small that an appreciable error is introduced if moisture is present in the thimble. The thimble should be dried at about 100 deg. cent. for two hours before using, and at the same temperature and for the same length of time after filtration.

Another method often used, and it is accurate, although perhaps more difficult of manipulation, is to aspirate the gas through a meter and catch the dust on a filter as before, measuring the gas volume and weighing the dust. In this method the balancing tubes are dispensed with, but the temperature and pressure of the gas passing through the meter must be determined, and the temperature in the conduit must also be known in order to calculate the dust concentration correctly.

FIG. 4 DETAILS OF APPARATUS USED FOR ENTRAPPING KNOWN VOLUME OF DUST-LADEN GAS

changes in velocity are occurring. This point is near the region of highest velocity rather than at the point of average velocity.

DUST DETERMINATION

After the gas volume to be delivered to the treater has been determined and the treater built and placed in commission, the question arises: How much of the suspended matter is the treater collecting? This is a natural question from the engineer's standpoint, for he always wants to know the efficiency of his apparatus, and also from the client's standpoint, for it behooves him to know whether or not any valuable material is being lost. Also, it may happen to be a natural question from the legal standpoint, for it might be necessary to know if any regulations regarding emission of fumes are being violated.

THE MANUFACTURE OF LEATHER BELTING

BY F. H. SMALL,¹ WORCESTER, MASS.

Non-Member

THE manufacture of leather belting has its beginnings on the farms of New England, the grazing ranges of the Argentine, the rocky Alpine pastures of Switzerland, the fertile plains of France—wherever cattle are raised. The cattle supply the hides which are one of the essential raw materials of the tanner and so of the belt maker. It is essential that the cattle industry should prosper if leather is to remain as universally usable a commodity as heretofore. Cattle are raised primarily for their labor value, their milk value and their meat value; the hide is very much of a by-product and the matter of production of a hide specially suited to the requirements of the tanner is but an infinitesimal incentive to the cattle grower. When steer hides sell at better than 26 cents a pound as they have this year, when as much as \$40.00 per hide must be paid to secure a particular selection, it seems as though the hide, even if but a by-product, represents a sufficiently large percentage value to secure from the cattle grower an endeavor to produce a satisfactory hide. The tanner, however, has had a hard time to establish this point of view although, aided by governmental agencies whose interests have been different but objective similar, progress has been made.

The particular evils of which the tanner has complained and for which the cattle raiser is responsible are three: barbed wire, brands and grubs. Barbed wire fences lead to scratches on the hair or grain side of the hide, which though they later heal yet constitute imperfections; branding destroys the hide fibre and makes so much of the hide as is touched by the branding iron absolutely worthless for purposes of belting manufacture; grubs are worst of all, for the reason that they do their damage in the very best part of the hide and oftentimes are so numerous that a hide affected by them gives the appearance of having been used as a target for a shot gun.

The first two evils are subject to individual correction; the last can be remedied only by concerted and wide-spread action. It is a question for governmental investigation and legislation. The investigation has been and is going on, but the efficient remedy is not yet, though progress is making. In one district in Denmark, for instance, where they can be reasonably autocratic, by making the presence of warbled cattle in herd punishable by fine, they reduced in six years' time the percentage of warbled cattle from 18 to 1. The above is mentioned for two reasons: *first*, to bespeak your interest in any measures that may come to your attention, calculated to improve the conditions mentioned, and *second*, to show you how uncontrollably imperfect is one of the tanners' raw materials.

Apart from damages as cited there are material differences in hides—differences in texture, in plumpness, in uniformity, etc. It is generally true, for instance, that cattle in warm

countries have thick hides and short hair, while in cold climates the reverse is true. Our supply of first quality, extra heavy hides comes almost wholly from southern Europe, and these being no longer obtainable as a consequence of the war we are hard put to it to produce extra heavy leather. Some cattle have hides which are very thick over the kidneys and thin over the shoulders; others show this difference much less markedly.

When the hide is removed, the way in which it is done is again a matter of keen interest to the tanner. Cuts in the hide made by the butcher when taking it off the animal lessen the value very materially. The *take-off* of hides from the large packing houses is usually excellent, the result of specific attention, carefully trained and expert labor. It is quite otherwise with the average country hides taken off by the town butcher, which despite the efforts of the Tanners Associations, are still a source of shame. The flaying is so bad that they rarely bring the price of a packer hide and they represent a real and needless economic waste. Abroad, methods of so-called mechanical flaying have been introduced to avoid butcher cuts. By these methods the hide is pulled and hammered from the carcass and such hides usually command a premium, 50 cents a hide being an average figure at the Paris auctions.

What happens to the hide after its removal from the animal and before the tanner gets it, is again of importance. Hide, being essentially gelatine, readily spoils and must be preserved against decomposition. Two methods of preserving or curing hides are in vogue, viz.: drying and salting. The first is ordinarily too uncertain to permit of the use of hides cured in this way for belting and practically all hides tanned for belting are what are known as green-salted hides.

If the belt manufacturer tans the leather which he makes into belting—and this is the ideal arrangement—he buys so far as possible green-salted hides, free from scratches, brands and grubs, short-haired, of as uniform thickness as obtainable and which have been skillfully taken off, so that they are free from butcher cuts; i. e., the manufacture of first quality belting begins with the purchase of first quality hides.

Before being used for belting these hides must be tanned, i. e., so treated that they will not decompose or spoil and will remain flexible. There are various methods of tanning hides but whatever the method used, the first steps, usually spoken of as the beam house treatment, are essentially the same, namely: preliminary washing with water to remove dirt and the salt or other material which may have been used to *cure* the hide; a cleaning of the flesh side to remove superfluous flesh, fat, etc., left on in the flaying—a soaking in milk of lime, or some other depilatory solution, to loosen the hair which is then pushed off by machine or with a dull two-handled knife; and a final washing to remove at least in part the mhairing chemical and to clean the hide. The quality of the finished leather depends in very large measure on the successful performance of these apparently simple operations. It is an old saying that leather is made in the beam house.

The conversion of the hide as above prepared into leather may be brought about through the use of any one of a variety of tanning materials, the peculiar characteristics of the finished leather being governed by the material used.

¹ Chemist of The Graton & Knight Mfg. Co.

Presented at the meeting of the Providence Association of Mechanical Engineers, affiliated with THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, September 22, 1915.

Only a few of these materials will be mentioned and such only as have a special interest to the belt manufacturer. One of the simplest and oldest methods of tanning is to cover the raw hide in the moist condition with grease and then continually manipulate it as it dries, thus working the grease into the inmost fibres of the hide and producing a grease-tanned leather. Grease-tanned leather has little more fullness or body than the original hide, but it is exceptionally strong. The so-called mechanical lace used for lacing together belting is tanned in this way.

Another method of tanning which has come down to us from olden times is to work into the hide a mixture of alum and salt. This gives a somewhat fuller leather than grease and is used before the grease treatment by some tanners of mechanical lace because of the fullness gained, but it is at the expense of the toughness and wearing qualities of the lace.

A modern tannage of somewhat similar nature is that with salts of chromium, the hide being immersed in a solution of one of these salts. Chrome tanned leather is fuller than alum tanned and much more permanent. Water will seriously injure alum-tanned leather, causing it to revert nearly to the condition of raw hide and to become hard and cracky, whereas water has little or no effect on chrome leather. Chrome leather may even be immersed in boiling water for some little time without serious damage to the leather. Most of the so-called steam-proof belting is made from chrome-tanned leather.

By far the greatest percentage of heavy leather, and in particular that used for belting, is tanned with a tannin derived from some vegetable material. The procedure of the tanning process as early practiced with vegetable materials was to spread the hides out flat in a vat with a relatively thick layer of the tanning material between the hides, the vat finally being filled with water. The water served as a medium of exchange, extracting the tannin from the vegetable material and giving it to the hide which absorbing it became tanned. The process was slow, often necessitating a year or two to effect the conversion of the hide into leather.

An improvement in the process was effected by substituting for the water a tan liquor obtained by leaching the tanning material in large tubs; i. e., extracting the soluble tannin by passing hot water through the ground raw material. Nowadays the use of the raw tanning material by the tanner is almost a thing of the past. He uses instead tanning extract prepared at plants usually located where the supply of raw material is abundant and which is a concentrated solution of tannin obtained by leaching the raw material with water as was formerly done at the tannery, and then evaporating away much of the water in a partial vacuum at low temperature and yielding as the commercial product ordinarily a thick brown liquid containing about 25 per cent actual tannin. Not merely does this supply the tanner with his tanning material in a form much more convenient for use, but it has the further decided advantage that the extract admits much more easily of analytical control and so makes possible the use of a determinate and uniform tanning agent. Since uniform product demands uniform raw material this is an improvement of no mean order.

Not so long ago—in fact as recently as 1890—practically all the vegetable tanned heavy leather in this country was made with either hemlock or oak bark, or a mixture of the

two. Now, while the old names, hemlock, oak and union, are still retained, it would be hard to find a tanner making leather with these materials alone. The present-day tanner uses not merely hemlock and oak, but chestnut wood, or valonia, or myrobalans, or mimosa, or quebracho, or wattle, or mallet, or algarobilla, etc., some twenty-five or thirty materials being commercially available.

With an increased range of materials came, of necessity, a study of the leather-making qualities of each. Marked differences appeared. For instance, the tannin of valonia was found to decompose rather rapidly, forming and depositing insoluble ellagic acid. The English tanner, earlier to use these materials, had discovered this by experience, and by using valonia and insuring the deposition of the ellagic acid in his leather, was making the solid English sole, water-proof and long-wearing, which earned him a reputation the world over. A myrobalan liquor was found to sour very rapidly, yielding eight times as much acid, for instance, as mimosa under the same conditions.

The leather-forming value of the materials varied; valonia would produce over 100 lb. of finished leather as against 75 for myrobalans, from the same weight of hide. Chestnut wood produced a leather of tensile strength over 3,000 lb. to the sq. in., while oak bark under similar conditions gave one of less than two. Here certainly was knowledge and opportunity the tanner could not neglect. Knowing what qualities he desired in his finished product, he could, by a careful selection of tanning materials, go far toward securing these qualities, this material making for fullness, that for strength, etc. The progressive tanner, who wanted to make the best belting leather could not afford to make oak belting with oak bark alone, and he did not, and his leather is the better in consequence.

The objection to practically all the tannages, aside from that with vegetable tannin, is that they do not make a plump, full, solid leather. The leather produced by them is tough, but thin and open. The original hide constitutes much the largest percentage of the finished product, only a small quantity of the tanning material remaining in the leather. This is in marked contrast to the vegetable tannage in which so much tannin and other matters is deposited in and on the fibres of the hide that the original hide constitutes less than 50 per cent of the final leather.

Lack of firmness is a serious deficiency in a leather to be used for belting. Nevertheless, leathers made with some of the above materials have sufficiently valuable properties so that they have made considerable headway for belting even despite their failings. Chrome leather, for instance, can be produced in a comparatively short time. It will run practically unharmed in a temperature where vegetable tanned leather would revert to a brittle, formless mass. It can be made exceptionally flexible. It has a high coefficient of friction. Consequently belting from chrome leather has found a place for itself, which would be larger, were it not for the deficiencies resultant from the lightness of the tannage, the lack of solidity of the leather and the necessarily high cost because of the small leather-yield. A leather tanned with a combination of alum and gambier, the gambier being used to supply the deficiencies of the alum as a filling material, has likewise had some vogue. It is tough and pliable, and has given good service for high-speed work.

The latest development in the way of a new tannage is that originated and used by the Graton & Knight Mfg. Co.,

with which I am connected, in the production of its Spartan leather. Spartan leather is a full, reasonably firm and solid leather, resembling in this respect the vegetable-tanned leathers, though more flexible. It has a higher coefficient of friction than chrome and consequently a better pulley grip and it will be remembered chrome is superior to oak in this respect. It is more resistant to heat and harmful agencies in general than chrome or any other leather. We have used it successfully for overload conditions so severe that engineers have said success was impossible. As an illustration, the worker roll on a Vaughn setting-out machine is run by similar belts traveling over similar pulleys at the two ends of the roll; in a service test we were using a chrome belt at one end and a Spartan at the other, alike except as to tannage. One day the chrome belt accidentally came off and to even our astonishment the machine kept right at work with only the Spartan belt in service. As a matter of curiosity we then reversed the conditions, leaving on the chrome belt, but it slipped and the machine refused to work.

It was stated above, that if the belt maker knew what qualities he wanted in the leather from which he made his belting, he could go far toward obtaining these by proper choice and application of tanning material. To enumerate these qualities as our experience has shown them:

First We need good driving surface, sufficient friction between belt and pulley to eliminate slippage as completely as may be and to enable the belt to carry its load under minimum tension, thus avoiding useless waste of power at the bearings;

Second Lateral stiffness coupled with pliability, the stiffness to keep the belt from twisting and waving and to prevent its curling at the edges when shifted; the pliability to enable it to hug the pulley, wrapping itself round and so securing large area of contact, and to enable it to alter its shape with the minimum of internal resistance as it travels round the pulley;

Third Good tensile strength that it may carry its load without breaking;

Fourth Little stretch but considerable elasticity; the former so that it will need to be shortened as seldom as may be, i. e., will do its work uninterruptedly; the latter so that it may easily take up and let go its load as it travels round the pulley;

Fifth Firmness or stability, much the same as lateral stiffness, so that the leather springs little when cut, holds its shape, remains straight and runs true on the pulleys;

Sixth Resistance to external conditions, such as heat, moisture, chemicals, etc.; that it may do its work in any place, at any time, and enduringly;

Seventh Low initial cost.

It is apparent that no leather can have all these qualities in the highest degree, for some of them are incompatible. Sole leather would do admirably as far as lateral stiffness, little stretch, and firmness are concerned, but would fail lamentably to satisfy the requirements of pliability, tensile strength, elasticity, etc. The best result we can achieve is bound to be somewhat of a compromise. We must aim to get the largest measure possible of the most desirable qualities in our leather, with the least necessary sacrifice of others. There is where the beltmaker who tans his own leather has a marked advantage in that he may bend all his efforts to so adjusting his tannage as to secure the best pos-

sible compromise. Quality belting demands then,—first, suitable hides,—second, suitable tannage.

We now have the leather and may proceed to prepare it for making into belting. Of the hides which we have tanned only 50 per cent may legitimately be cut up into belting and less than 40 per cent will go into first quality belting. First, we reject the bellies, cropping or cutting them off at the flank; this loses us 25 per cent of the hide. Next we cut off the shoulder at a point 4 ft. 4 in. from the tail or, if the hide be exceptionally small, at a less distance; this loses us 25 per cent more, leaving us for cutting into belting a "bend" which constitutes less than 50 per cent of the original hide.

This bend has now to be carried, i. e., given a supplementary grease-tannage; set out—to give a smooth flat piece of leather and then stretched. The stretching is done on frames in which the wet leather may be clamped and subjected to so much tension as desired, the leather being allowed to dry under tension on the frames so that an additional stretch resultant upon the natural shrinkage of the leather in drying is imparted to the leather. Before being stretched the bend is usually cut into a center and two side pieces, inasmuch as the center portion being more close fibred will not stretch as much as the side pieces and by being divided as above the leather can be stretched more in accordance with its capacity. After stretching the leather is rolled and glassed to improve its looks and is then ready to go to the stock room.

When the leather is received in the stock room, it is sorted according to weight or thickness—which in this connection are practically synonymous terms—into extra heavy, heavy, medium and light, and then packed down for future use. The sides are packed in square piles, alternate layers at right angles, to keep the stock flat and straight and allow of a circulation of air through the pile, thus aiding and hastening the seasoning process. This seasoning is an often neglected but most desirable operation, for the use of well seasoned leather is as important in the manufacture of belting as the use of well-seasoned lumber is in building. Belts made from well-seasoned stock stretch less and more uniformly, retain their elasticity and wear longer than belts from green stock.

From the stock room the leather goes to the belt shop where its manufacture into belt takes place. The first step in this process is to straighten one edge of the leather. Next it is cut into strips of various widths by passing between a rapidly revolving circular knife and a guide, the strips being graded for width and roughly for quality as they come from the knife, and then stored in racks. From these racks the leather goes to the sorters by whom it is most carefully graded, both for thickness and quality, and on their expertness depends the maintenance of the standard set for each brand of belt. Accurate judgment of quality depends on wide experience in handling leather and a good all-round knowledge of the specific characteristics of the leather in different parts of the hide, for it is a fact that no two square inches of hide are precisely alike.

Quality, however, is very elusive of definition when one tries to imprison it in the confines of a specification and the buyer is fully as likely to be well served if he states his needs and trusts to the honesty of an established and reputable house as if he attempts to be his own judge. The author has in mind a large railroad buying belting accord-

ing to a specification which called for the leather to be cut from strictly first quality belting butts and they were getting it, *nicks* and all. Inasmuch as a belt is no better than the poorest strip in it, similar to the chain that is no stronger than its weakest link, it may be imagined how well they were being served. Later when the author's company had an opportunity to supply this railroad with some belting, we were rather chagrined to have it rejected by the railroad inspector. Some rolls of stock belt of a grade distinctly inferior to that first offered were then submitted and accepted by the inspector with a cheerful response: "That's what we want; why didn't you give us that at first?" For our own ultimate good we have been trying to educate that railroad on this subject of quality in belting.

Returning to the process of manufacture, after the strips have been sorted, they then go to the *fitlers* to be matched and have the laps marked. Pieces cut from the right side of the hide are matched with pieces cut from the left side, because all strips which are not backbone center pieces will stretch in a curve if subjected to a sufficient strain. Narrow strips from a properly stretched side, merely as a result of the stripping, contract to a slight curve. Belts made by joining alternately rights and lefts will roll out in a curve on the floor but will run true upon the pulleys, while belts in the construction of which no attention is paid to the matching of rights and lefts will roll out straight on the floor but will invariably stretch crooked if subjected to sufficient tension on the pulleys. Not all belts show these characteristics noticeably because not all belts are required to transmit sufficient load to develop them early enough in the life of the belt for them to attract attention.

The laps are marked according to the thickness of the stock and usually range between 4 in. and 10 in. in length. Laps must be longer on the shoulder end of the piece because hides become thinner, taper off faster, near the shoulder than near the rump, and longer laps are needed therefore to maintain a uniform thickness of belt. Shoulder ends are joined to shoulder ends and butt to butt because the length of the laps match better, the thickness is more uniform, the stock is similar in quality and the component parts will therefore wear and stretch more uniformly. The laps are next scarfed and prepared for cementing.

The usual cement employed to stick the laps has for its basis animal glue. Each manufacturer is likely to have his own pet formula calling for certain additions to the glue solution and particular methods of compounding, but they all look much alike. By this it is not meant to disparage the cement, for a cement that will hold as long as the leather will wear, is a necessary component of a quality belt. About twelve years ago saw the beginnings of the now indispensable waterproof cement. Laps stuck with this are absolutely unaffected by water, either cold or hot. Whatever cement is used the process of *sticking* is the same in its essentials. The surfaces of the leather to be joined are coated with the cement, put together in their final position, placed between the plates of an hydraulic press and subjected to heavy pressure. From the presses the belt goes to the inspector and then to stock.

The above description applies more particularly to single belting, but the processes are much the same if double or three-ply belting is to be made. A liberal quantity of stock which has been scarfed and the flesh side of which has been cleaned up with a scraper to remove grease, loose flesh, etc.

(this being the side which is cemented) is placed upon the fitter's bench. He matches these together on a smooth surface against wooden blocks which are his standard of thickness, the pieces being matched to secure as uniform thickness as possible and so that the laps of one ply come about half way between the laps of the opposite ply.

In conclusion, I wish to emphasize the fact that the idea that a belt is a belt and one need merely cut off a piece of the requisite length and put it on the pulleys is no longer tenable. Proper mechanical conditions and adaptation of belt to drive are just as essential to economy of operation as is the suiting of a motor to the work it has to do. As illustrating the first might be mentioned a three pulley quarter-turn drive with fixed idler that came to our attention. This required an 11 in. belt and was called upon to transmit 100 h.p. The best belt procurable lasted about two months on this drive. Changes in the plant demanded more power from the drive and it was altered to a five-pulley quarter-turn, which necessitated the use of nearly three times the former length of belt. A belt an inch wider is delivering double the horse-power and is good for at least ten years.

Returning to the railroad, their theory of operation was to keep rolls of belt in stock and cut off a length as it was needed. On one machine of which they had record, the average life of a belt was six weeks. Our belt man succeeded in securing the installation of a belt suited to the drive and at last accounts this belt had been in operation over six months and was apparently then in perfect condition.

Another illustration of suiting the belt to the drive: A customer complained that an 18 in. edger belt furnished him was not working satisfactorily and one of our belt men investigating the conditions, found that at the high speed at which the belt travelled, the load was not sufficient to keep the belt down on the pulleys, the edges raising. The belt was narrowed two inches to 16 in. and did the work perfectly. An opposite case was that of a 6 in. light double belt on a high speed drive, long centers, power off and on frequently. The belt jumped so badly it could not be used. A heavy double was substituted and the trouble ceased at once.

The weave room in a cotton mill was belted with medium weight first quality belts and the plant was not a paying proposition. A study of conditions convinced our belt engineer that they were using too light a belt and the belts were replaced with heavier first quality belts, and the plant was able to pay dividends.

Another similar illustration: Our salesman recommended a light double belt for a mill drive, the master mechanic of the mill insisting on a heavy single. There were several similar drives, so one of each was installed. The record of the belts was that the double was taken up and shortened 2 in. five days after installation and not touched again when this record was completed, while the single was shortened 2 in. the day installed, 2½ in. two days later, 4 in. three days after this, 3 in. more sixteen days later, 3 in. more forty-six days later, and 5 in. again after 29 days more, when it was practically worn out.

The subject has been so large for the time at disposal that this talk may have been much cursory and little interesting. It however may have served its purpose if it has shown you something of the problems of the business and of its ramifications—that many of its simplicities are really complexities.

AN INVESTIGATION OF THE GAS-PRODUCER POWER-PLANTS IN NEW YORK CITY AND VICINITY

BY C. M. RIPLEY, NEW YORK

Non-Member

THE object of personally visiting all the gas producer plants in New York City and its environs was to acquaint the author with the progress which had been made in the use of gas producer power plants and the present status of the industry as applied to a large city and its suburbs. It had been suggested that most of the information available to owners and engineers on this subject emanated from the sales departments of various manufacturers; also that these manufacturers report only upon plants which they themselves install and then upon only the more successful ones; and that an unbiased investigation might be interesting to the Gas Power Committee of the American Society of Mechanical Engineers, and also to those of the business community who operate properties involving large annual expense for heat, light and power.

The investigation covers the size, age and performance of the gas producer plants and a census was taken of owners' opinions regarding repairs, labor and depreciation. The three different phases of this investigation are as follows:

- I. A census recording owners' opinions. (Table 1).
- II. Technical data, showing capacities, performances, etc. (Table 2).
- III. General information from personal inspection and interviews.

On Tables 1 and 2 plants are arranged according to their size, i. e., from 1000 h. p. down to 30 h. p. of producer capacity. In the division of general information the plants are taken up according to their age in service, i. e., from sixteen years down to less than one year.

CENSUS OF OPINIONS

To each of the owners of gas producer plants in this district was written the following letter:

Gentlemen:

I wrote you early in the month requesting a "yes" or "no" answer to these questions about your gas producer plant:

Ques. No. 5. Are repairs in excess of your expectations?

" No. 6. Is depreciation in excess of your expectations?

" No. 7. Is labor charge in excess of your expectations?

" No. 8. Are you availing yourselves of the heat in jacket water and exhaust?

" No. 9. If you were to construct another building for similar uses would you again install a gas producer plant?

The idea of this investigation of all the gas producer plants in New York City and in near-by towns in the Metropolitan District is to ascertain the progress made by gas producers, their present status and the general opinion of those who operate them.

In return for this information I will be pleased to send you a copy of my complete paper with charts and the result of the census. It will be interesting for you to know what the other users of gas producer plants think of this system

of power, and in the future if anyone asks information of you about your plant you can refer them to the library of the American Society of Mechanical Engineers, where in all probability their questions will be answered.

Thanking you in advance,

Yours very truly,

(Signed) C. M. RIPLEY.

The answers to these questions are tabulated in Table 1 and lead to a most interesting conclusion as to the present status of large gas producer plants. As a constructive criticism it is to be hoped that manufacturers will profit by a study of this chart and that their product will be improved where weakness has been shown. That this will be the case in the next few years the author feels confident.

The fact that 78 per cent of the gas producer plants in this territory gave definite answers to a majority of the four questions indicated at the top of the chart, is very gratifying. It will be noted that 86 per cent of the large plants, i. e., 250 h. p. and larger, answered the questions fully, whereas but 74 per cent of the small plants gave answers to these questions.

In regard to question No. 5, it is interesting to note that 80 per cent of the large plants report repairs in excess of their expectations and that only 6 per cent of the small plants so reported. The satisfaction with the small plants in regard to this question is indicated by the fact that 94 per cent of them answer "no."

In regard to question No. 6, 56 per cent of the large plants report depreciation in excess of their expectations, while 94 per cent of the small plants report the contrary.

In regard to question No. 7, 50 per cent of the large plants report attendance costs in excess of their expectations, while 88 per cent of the small plants do not find this to be the case.

Question No. 9 asks for opinion as to installing a gas producer plant in case a new factory were to be built. 50 per cent of the larger plants answer "yes," 30 per cent "no," and 20 per cent are doubtful. Should this 20 per cent be interpreted as meaning "yes," then the large plants would indicate 70 per cent favorable answers against 86 per cent favorable answers from the small plants. Should "doubtful" be interpreted as "no," then 50 per cent of the large plants may be considered unsatisfactory as against 14 per cent of the small plants.

Attention is invited to this Table as it gives a tabular measure of satisfaction and dissatisfaction. The answers as shown to the four questions constitute practically a curve in which satisfaction is plotted against size, and can be visualized without difficulty.

TECHNICAL DATA

In Table 2 will be found information as suggested for convenience of reference and comparison, from which it will be gathered that there are fifteen gas producer plants in New York City, and a total of thirty-three in operation in the Metropolitan District. This is in addition to two

¹Consulting Engineer, 110 West 40th St.

Presented at the New York local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on November 9, 1915.

experimental gas producer power plants, three gas producer plants used for furnaces only (not in connection with power plants), and seven gas producer power plants which have been abandoned.

Kind of Coal Used. It will be noted that only two of the thirty-three plants referred to above are using bituminous fuel, all of the rest using either pea or buckwheat anthracite.

One general impression obtained by the author is that only slightly more fuel is used in these plants for a 24-hour

TABLE 1 CENSUS OF OWNERS' OPINIONS

run than for a 12-hour run. This is due to the following, as stated by one expert in gas producer operation:

It is common practice in the majority of gas producer plants to remove more or less green fuel with the ash, when cleaning fires. Usually the percentage of combustible matter in the ash grows smaller as the hours of operation increase and the load on the producer approaches a maximum.

In a producer that is underloaded and running on an average of 10 hours in the twenty-four, combustion is not rapid enough to allow for lowering the entire fuel bed, and more or less green fuel is removed by the average operator, this being an easy and convenient way of maintaining the fire in a good gas-making condition.

A skilled operator can usually obviate this difficulty by studying his fire and cleaning it according to the position and amount of the ash. His method would be approximately as follows: A normal fuel bed produces an ash deposit, the

part of which in contact with fuel, has the shape of a bowl. This is due to the draft following the sides of the producer and in case of an underload on the fire and the draft being reduced, a larger percentage follows the sides than would under full load conditions.

This means that the operator must clean the side walls thoroughly and practically leave the centre of the fire untouched. As the majority of producers are so designed that this is a task which only a skilled operator can perform successfully without removing considerable green fuel mixed in the ash, the average plant shows a large amount of combustible matter in the ash.

Different types of producers are more or less adapted to meet these conditions. The type designed in such a manner that the fuel bed rests on a solid ring on the side and a shaking grate in the centre, meets the above conditions better than any other. It enables the operator to remove the wall ash a little at a time and by poking around the wall, between the removals, to gradually lower the bed at this point to the proper level, without losing any good fuel. After this is done, by shaking the grate, the centre also can be cleaned.

Where the fuel bed rests entirely on a shaking grate, if the walls are cleaned in the manner described, green fuel is shaken down when the centre is lowered. If the grate is resorted to to lower the entire fuel bed, much good fuel is removed from the centre before the walls are properly clean.

In producers using a turn-table and bars to scrape off the ash accumulation the same result follows. In producers having a water seal, and relying on the cone effect of the ash bed around a tuyere, to allow for the removal of ash of the shell, runs occur owing to the fact that the operator cannot see the fire as he works it, and does not know at any time the exact position of the fire. All these difficulties may be more or less overcome by a skilled operator who studies his fire.

The fact that a producer can be run 24 hours with much less fuel in proportion to the load carried, than for 10 hours, is due to a great extent to the foregoing. A normal producer, if properly handled, should show a standby loss of not over 5 per cent of the grate rating. Also standing idle tends to make the fire climb into the fuel magazine and due to the heat generated, cause the operator to pull more or less fuel in order to permit the addition of more green fuel to cool the top of the producer.

Any moisture entering the bottom of the producer when it is standing idle, tends to drive the fire to the top and leave the bottom filled with partly consumed and useless fuel.

These conditions may not apply in all cases but nearly all fuel waste is traceable to them (in one form or another) or to poor design.

Height. It will be noted that considerable headroom is needed for the gas producers even in the small plants. This, however, has been overcome in two plants by locating the producer out-doors, thus saving excavation, and with apparently no bad results. In regard to the space occupied by the producers, it is surprisingly small in relation to the amount of power obtained from them.

Attendance. It will be noted that the anthracite plants seldom need over six charges a day even for a 24-hour run, and the cost of firing is small indeed. In fact operating men consider the firing, as far as the amount of time is concerned, a great advantage as firemen can be useful at other work during a vast majority of the time. In many cases the engineer does the charging himself as it requires so little time and effort, especially with the electric hoist or other coal elevating devices. The removal of the ashes under these conditions is left to a laborer. The operation of plants of 300, 400 and 600 h. p. with the consumption of one, two, three and four tons of coal per day is to be noted, several cases showing these results in a 24-hour run.

TABLE 2. TECHNICAL DATA OF GAS PRODUCER POWER PLANTS IN NEW YORK

As a general impression, it would appear that the importance of skill on the part of the engineer in charge is greater than estimated by the average salesman, and several owners have engaged second and third class operatives and paid the price to their sorrow. To a large extent this error is, in the author's opinion, to be laid at the door of the sales departments of the manufacturers, and it is hoped that they will advance their interests by being more careful as to their claims in the future. It is true that the firing of the coal is a very small matter, but the care of the gas engine and producer cannot be entrusted to a third class man or a laborer, as some have vainly attempted to do.

Some owners are using the unconsumed coal in the ashes for firing boilers, and one owner carries it to a point that he not only heats his factory but his residence with the mixed ash and coal removed at the end of the day's run.

GENERAL INFORMATION

The Oldest Gas Producer Plants. The oldest gas producer plants in operation in the territory investigated is at the Erie Railroad Company's terminal in Jersey City, N. J. For 16 years the same producers (Wood pressure type) have been in use and while the Railroad Company refused to contribute to the author's census of opinions, their satisfaction may be gathered from the fact that they have made additions to this power plant upon two separate occasions. Two 90 h. p. Otto engines were later supplemented by three Otto and one Westinghouse engines, and later again augmented by another Westinghouse engine. William S. Young is the mechanical foreman of this plant. Both alternating and direct current electricity is generated and both direct connected and belted drives are used.

Another old plant is that at the Phoenix Tube Works, Brooklyn, which for thirteen years has had no other source of power than gas producer plants. They use one Smith and one Tait suction producer, and as in the previous instance, have twice enlarged their plant. They have, for attendance, but one man who does his own charging and that but once per day of 10 hours. If they wish to run at night they run one of their engines with city gas. The engines are direct-connected to electrical generators.

In the tenth year of service is a plant owned by Thomas Wright, wagon maker, in Jersey City, N. J. In an interview Mr. Wright said: When we purchased electricity it cost \$6.25 per day for power. When we purchased street gas and ran our gas engine it cost \$4.85 per day for power. With the present plant it costs \$1.00 per day for power. I wish to go on record as saying that had I not invested in this economical plant when business was good in 1905, I would have been forced to retire from business.

This plant has had several shut-downs due to careless handling, and in his letter Mr. Wright states that the gas producer plant is profitable but the man taking care of same must be useful and interested. He also states that his repairs from 1906 to 1914 have been so small that he hardly notices it. Also, that the labor charge is not excessive, considering what they would have had if operating a steam engine. This engine is chiefly belted to the load.

Plants in Ninth Year of Service. The Pirika Chocolate Co., in Brooklyn for nine years, have depended on their gas producer plant for power and for a great deal of their heat. Mr. George C. Stout says, "If all gas producer plants ran as ours has run, there would be no other kind of power plant in the world." This plant emits no smell, the pro-

ducer being located out-doors, and they state that the increased consumption of fuel during the winter months, which they attribute to the location of the producer, is only thirty pounds, or 6c. per day. The firing requires one hour per day of a ten dollar a week man. The repairs to the producer outfit for eight years have been about \$40.00 and the repairs to the engine have cost about \$50.00.

Twenty-eight kettles are heated at the Pirika plant by forcing the cooling water from the jacket of the engine through the kettles by means of a small electric-driven turbine pump, using one ampere. The cooling water goes into the jacket at 160 deg. and emerges at 190 deg. Fahr. It is quite an achievement to run a factory building 35 x 110 ft., three stories and basement, and burn only 75 tons of fuel per year. Mr. Stout opened his records for years back and showed the average to be no greater than as shown above. Smith producers and Nash engines are used in this plant, belt-connected to the load. They used a barrel of oil a year for engine lubrication.

Hawley & Hoopes, another candy manufacturer, on Manhattan Island, New York, have used a gas producer plant for nine years. They also have a steam plant and electric connection from the street for night work. They use Wood producers and Westinghouse engines, direct connected, and the plant gives entire satisfaction.

Strobell & Crane, jewelry manufacturers in Newark, N. J., who occupy a building 75x160 ft., five stories high, operate an Industrial gas producer and Westinghouse engine, direct connected to a generator and belted to other power. The engine has run nine years and ran six years without the cylinder heads being taken off. They also have a connection with the street electricity.

The John Thompson Press, Long Island City, has operated a gas power plant for nine years. This power plant is in a separate building and the plant gives satisfactory service. The factory building is 80 x 165 ft., three stories in height. A Wood producer and Nash gas engine, direct connected to the generator, are used. George W. Day is chief engineer.

The National Meter Co., of Brooklyn, have a gas power plant comprising Smith producers and Nash engines, direct connected, nine years old, which was enlarged three years ago and again two years ago. The building is 50x315 ft., four stories high, and the grounds surrounding it are 200x500 ft. This plant developed 12,200 kw-hr. per week of 55 hours and is only charged twice per day. An electric hoist is used to advantage for charging each of the producers. They sold their steam engine and have no connection with the street electricity.

N. Drake, at Newark, N. J., has a nine-year-old plant in his coal and wood yard and grain elevator. They have had no trouble since the first three months and charge but once a day for an 11-hour run. The attendance is less than one-half of one man's time in addition to the supervision of Arno Morgner, foreman. The engine is belted connected to the load.

Plants in Eighth Year of Service. Leiman Brothers' pump works at Newark, N. J., give an interesting example of the reincarnation of a dead gas producer plant. These people for three years have operated with entire success and satisfaction a plant which was an utter failure during the five years it was at the Newark Spring Mattress Co. The Mattress Co. abandoned the plant in disgust and changed to

street electricity at less than three cents per kw-hr., but refused to state the exact rate which induced them to abandon the unsatisfactory plant.

Mr. George Leiman, of the above company, obtains from the ash of his gas producer enough coal throughout the year to heat his factory and one other building. The attendance of this plant requires two hours daily of a helper and the careful attention of the foreman of the shop, who is a first-class mechanic. Mr. Leiman states that they have less trouble than with the ordinary steam plant and is entirely satisfied with the outfit.

Another eight-year old direct-connected plant is at the Max Aus Machine Co., of Mount Vernon, N. Y. They wrote in 1913, "Very well satisfied with the system and would not exchange for a steam plant, nor will we consider a steam plant when we are in need of an additional plant." Their answer to the census in 1914 indicates a growing interest in the semi-Diesel oil engine. They use the De La Vergne gas engine, which the De La Vergne Co. state they no longer manufacture.

The McCabe Hanger Co., on Manhattan Island, have used for eight years an Otto engine and producer. This is of low speed and noisy, but is very compact and emits no smell. The owner has a well for cooling water. In the eight years of operation, he claims to have had but one shut-down due to the engine and no shut-down due to the producer. There were twelve stoppages, however, due to bad bearing lubrication. Mr. McCabe's opinion is that producers below 100 h. p. are more satisfactory than those over 100 h. p. Mr. McCabe's plant is less than 100 h. p., direct connected.

Swift & Co., in the Bronx Borough, N. Y., have operated a large plant for generating electricity and refrigeration for eight years. Smith suction gas producers and Rathbun-Jones engines are used, direct connected to generators. The refrigerating machines are driven by motors. The plant is never shut down. Mr. W. F. Frazer, the chief engineer, says that, properly cared for, the labor charge is the same as a steam plant of the same size. A low pressure heating system is installed in the upper portions of the building. They are availing themselves of the heat in the jacket water and exhaust only for heating a small amount of water required as a spray in the producer.

Charles Mundt, of Jersey City, whose business is to punch metals up to $\frac{1}{2}$ in. in thickness, has a factory 50x250 ft., two stories in height, and has operated on gas power for eight years. The man who cares for the engine and producer works regularly in the shop. This plant has been enlarged and improved, and the old engine is used with city gas as auxiliary. Otto producers and engines are used, belt-connected to the load.

T. Shriver & Co., Harrison, N. J., conduct an iron foundry and machine works and for eight years have used gas producer power. They charge but twice during the day's run and have one Otto producer and engine and one Westinghouse producer and engine, both belt connected to the load. They did not answer the census.

The Universal Metal Bed Co., Brooklyn, N. Y., lease a building and producer plant formerly operated by the Star Engravers' Supply Co. This plant is eight years old. Mr. R. J. Zapkin is superintendent, and supplied this information.

Plants in Seventh Year of Service. The Keystone Watch

case Co., Jersey City, N. J., have for seven years operated a Harvey producer and two Westinghouse engines, direct connected to electric generators. They have had no shut-downs in the last several years. They also use producer gas in the brass foundry and in ten forges. The engine room is cool and light and has almost no odor. They have a steam auxiliary.

The De La Vergne Machine Co. have operated a gas producer plant for seven years, but state that they have ceased manufacturing them.

The Ludwig Piano Co. have a six-story factory in the Bronx, New York City, and have operated a Koertgen gas engine and suction producer for seven years. When inspected they were adding a 200 kw. steam engine, as considerable steam is used in their drying rooms. The chief engineer states that he can start up his plant in 25 minutes, including the making of a fresh fire. The coal withdrawn with the ashes at night from the producer is burned under the boilers. Granville Gibbons is chief engineer. He states that when the producer was being repaired they ran the engine with street gas.

Allsopp Brothers, jewelry manufacturers, of Newark, N. J., have a factory 30x100 ft., five stories high, and have operated a Backus engine and producer for seven years. They are operating apparently satisfactorily in a cool room. The engine is belted to the load and the electricity from the street is purchased for light only. They have gas connection with the street.

Plants in Sixth Year of Service. The General Cement Products Co., and the Auto. Fire Protection Co., who are the joint tenants in a two-story 50x100 ft. factory building at Whitestone, L. I., have operated a producer gas power plant for six years. Smith suction producers and Nash engines are used. Mr. Thurston, the chief engineer, states that all machinery is motor-driven. The producer is charged once a day, in the morning, with 250 lbs. of pea coal. At 6 P. M. the shop is closed and locked, leaving the belted engine running alone all night, carrying a 50 amp. night load, which it is claimed has been done for four years. During this time the plant has supplied electric light for a residence, barn, and outdoor lighting on the country estate of R. L. McElroy adjoining. Also, electricity is used for cooking twenty meals per day at the residence. The supply of electricity for this residence, it is claimed, supplants an electric bill of \$320.00 per month at an expense of less than \$85.00 per month, including interest and depreciation. The residence contains a Simplex No. 11 cooking range, which replaced an old coal range five years ago. When cooking with coal it required two tons per month of \$6.00 coal. With the electric range and the increased electric consumption for operating same, the producer burns one ton per month extra at \$4.00 per ton. Besides the electric range are three electric irons, three electric hot plates, a waffle iron, one electric toaster and one electric percolator.

Plants in Fifth Year of Service. The Horton Ice Cream Co., New York City, who operate an ice cream factory, 200x100 ft., five and six stories in height, have used producer gas for five years. Besides operating forty motors for machinery, they also operate seven electric elevators. The total motor load is 810 h. p. The engine room is cool and quiet, but the producer room is terribly hot. This latter condition is largely because tenants in the apartment houses

nearly complained of the noise of firing, and in deference to their wishes the company bricked up the producer room at the expense of ventilation. H. J. Ayers is chief engineer. Tait suction producers and Rathbun-Jones engines are used, direct connected to electric generators.

The Atha Tool Co., Newark, N. J., who have been using producer gas power for five years, have five buildings, covering six and one-half acres of ground. This is one of the producer plants in the Metropolitan District which operates on bituminous coal, Loomis-Pettibone suction producers being used. Mr. Hausman, the superintendent, escorted the author through the plant.

The gases from the producers are passed through a vertical boiler before going into the scrubber and dryer. This boiler generates 80-lb. steam pressure, which operates the blower engine, pumping the gas to the outdoor holders. The same producers make water gas and producer gas alternately every few minutes. The water gas is used in the furnace of the forge shop.

Before installing the gas producer plant the Atha Company spent \$20.00 per day for coal for the 42 furnaces in the forge room. With the gas producer plant they burn less than eight tons of coal in a 12-hour day, which displaces the old method of heating in the forge room and also gives them about 500 h. p. of Westinghouse engines direct connected to dynamos.

The Hooten Cocoa & Chocolate Co., Newark, N. J., have for five years operated a Fairbanks-Morse producer and gas engine. This is one of the cleanest, coolest, odorless and best appearing plants which the writer has seen. High ceilings, good light, and exquisite cleanliness contribute to the result. One first-class mechanic runs it with the assistance for a few hours daily of a low-priced helper. G. B. Griffith is in charge of the producer engine and dynamo. F. H. Sterner is the steam and refrigerating engineer of the factory. Mr. Griffith states that the repairs on the producer plant in three years have amounted to about \$100.00.

A decided novelty in this plant is that the producer apparatus and piping were all painted with aluminum paint, adding to the lightness of the room and establishing a standard of cleanliness throughout. The operator also designed a novel ash pan under the cleaning door with an apron shaped to the curvature of the producer, which prevents the dust and ashes from getting on the floor during the process of pulling the fires. This pan has handles at either end, making it portable and permits the ashes to be entirely removed from the building with ease after each cleaning process.

The Hooten Company also has a belted steam engine not in use. They purchase alternating current electricity from the street for running part of the factory and generate direct current in their gas producer plant.

Mr. George F. Heinrichs, who operates a meat market in Manhattan Island, New York, 120x150 ft., part three and part two stories in height and irregular in shape, has operated with producer gas for five years. This is a quiet running plant with no smell or vibration, and is one of the best plants from the standpoint of operation. Mr. J. Ruf is chief engineer. The Hill-Hoplet suction producer and Struthers-Wells gas engine are used, direct connected to generators. Mr. Ruf thinks that the manufacturers over-rate the producer and also over-rate the engines.

The Auto Press Co., College Point, Long Island, have a

factory 60x100 ft., three stories high. Their producer power plant is in the fifth year of service and runs five days per week, nine hours per day. They have had one shut-down due to careless engineer and since inspection have reported more trouble. The engine is belt-connected to the load.

Plants in Fourth Year of Service. Winelander & Jackson, who make steel lined brass pipe for beds, etc., have a factory 200x100 ft., one story high, in Brooklyn. The engine is located in a pit at the center of the shop and is belted to the shafting and to a small motor used as a dynamo and furnishing all electric light and power. The engine runs quietly and emits no smell whatever. The tool maker takes complete charge of it and a night watchman cleans the fires at night and charges in the morning. For a 12-hour run they use 1000 lb. of pea coal and for a 24-hour run they use 1500 lb. of pea coal. Mr. E. Ebke is the superintendent. This plant is a pronounced success and has been in operation since July, 1911. A Smith producer and Nash engine are used, with belted connection to the load.

The Acme Electric Garage, 410 East 32nd Street, Manhattan Island, has been enlarged three times since it was installed four years ago. The building in which the garage is located is a nine-story loft building. Wood producers and two Bruce-Macbeth engines, direct connected to generators. When inspected the plant was being increased in size—close to 600 h. p.

Plants in Third Year of Service. The Erie Railroad Co. had a gas producer plant in North Paterson, N. J., which was later removed to Croxton, N. J. This gas engine was belted to the shaft and ran satisfactorily with three or four shut-downs in three years. The master car builder stated, "A pile of coal now and then, just like firing a base burner parlor stove." This plant was removed from North Paterson because it was too small for the work. It is belt connected to the load.

Plants in Second Year of Service. The Mergenthaler Linotype Co., Brooklyn, N. Y., have a satisfactory working outfit consisting of a Smith producer and Rathbun-Jones engine. This was one of the plants where the producer was located outdoors. Above it is an electric hoist for charging, which is covered by an ordinary corrugated roof to protect it from the rain. The gas engine is working in parallel with four steam units, all delivering electricity for the operation of the factory. R. J. Meadows is the chief engineer.

The American Cotton Oil Co., Guttenberg, N. J., have operated a plant for two years, consisting of Smith producer and Allis-Chalmers engines, direct connected. They have recently changed from pea coal to buckwheat coal.

Castle's Ice Cream Co., Newark, N. J., have a producer plant in its second year of service. They also have a steam plant. The gas power plant consists of a Smith producer and Nash engine, direct connected to a dynamo.

Plant in First Year of Service. L. O. Koven Brothers, makers of stoves, ranges, etc., in Jersey City, are operating two Loomis-Pettibone suction gas producers for bituminous coal and one Westinghouse engine, direct connected.

Experimental Plants. Standard Motor Construction Co., Jersey City, installed a gas producer plant more or less as an experimental proposition, with a view to adapting gas producers to marine work. The experiment was not a success. The Loomis-Pettibone producers were in use for five years and are now for sale.

Stevens Institute, at Hoboken, N. J., have an Otto producer and gas engine, and also a Nash and a Mietz & Weiss gas engine, which are used for instruction purposes. These are direct connected.

Gas Producer Plants for Baking. The Cork Insulation Co., Jersey City, have two Smith producers generating gas to heat the ovens for baking cork insulating block. They have done considerable experimenting in the mixtures between pea and buckwheat in order to get a stable fire with free burning qualities, which will allow them to force the producers above their rated capacity.

The Hyatt Roller Bearing Co., Harrison, N. J., have 500 h. p. Westinghouse producers used for making gas for furnaces. They use bituminous coal and have the down and up draft system.

The Crucible Steel Works at Harrison, N. J., use two Hughes gas producers for open hearth steel process and they are reported very satisfactory.

Defunct Gas Producer Power Plants. Mr. C. E. Hertlein had no success with gas producers in his factory in the Bronx, New York City. They bought one plant in 1907 and in 1909 they bought another. Although the expert from the manufacturer tried to teach their steam engineer, it was unsuccessful. This was partly due to interruptions to service and partly due to the fact that live steam was required in their dye house. They found that exhaust steam from steam engines was just as good as boiler steam, and that with the steam engine running for making electricity their coal bill was about the same as when the gas producer plant was running. He now generates his power by steam engine.

The Cameron Machine Co., Brooklyn, N. Y., installed in 1907, a second-hand belted gasoline engine. The writer was informed that it was later changed to a gas engine for street gas and then was again altered to a gas engine for producer gas. They found it preferable to buy their electricity from the Edison Company.

The New Jersey Adamant Mfg. Co., Harrison, N. J., used a producer for three years and after changing the line of manufacturing sold the producer plant. They state that it worked satisfactorily.

The Harper Brick Co., Harrison, N. J., used a plant for two years but later sold it. They now use a steam engine for hoisting at the dock as the service is intermittent.

The Newark Spring Mattress Co., Newark, N. J., laugh at the suggestion of using gas producer power. They found it generally unreliable and said that all the experts in New Jersey couldn't make their plant run. This is the plant sold to Leiman Brothers machine shop, where it has operated with entire satisfaction for over three years. Apparently the success of a gas producer plant depends largely upon its environment, because here was a failure converted into an unqualified success, apparently by virtue of supervision.

The Public Service Corporation replaced the Newark Spring Mattress Co. with their electric service at a rate "much less than three cents." Mr. Odell, of the Mattress Co., stated, "I have nothing to remark except that we are perfectly satisfied with the arrangement."

The Adriance Machine Co., Brooklyn, N. Y., purchased a gas producer plant second-hand, but never unpacked it from the boxes, inasmuch as they completed satisfactory arrangements with the Edison Co.

The Manhattan Sewer & Stamping Co., when inspected,

had a gas producer plant with 75 kw. dynamo which is for sale. The firm retired from business.

As far as the writer can see, the failures of gas producer power plants are approximately 21 per cent of those which have been installed in New York City. Information from another source indicates that among the independent electric plants using steam in Manhattan Island, about 10 per cent have been shut down and replaced with Edison service.

It is a question as to whether the percentage of mortality for gas producer power plants is not low when we consider the comparatively recent development of internal combustion engines and gas producer as compared with the history of the development of steam.

The mortality rate for all the gas producer plants of which the writer has a record, indicates that 17 per cent of the number of these in New York and the Metropolitan District have been discontinued. One of these cases was where the firm owning it retired from business.

The writer wishes to acknowledge his indebtedness to Messrs. Frank A. Pattison, Charles E. Pattison and D. D. Kimball, Consulting Engineers, whose generous and unselfish help made possible the collection of this information.

DISCUSSION

JOHN H. NORRIS: In connection with the National Meter Co.'s plant, data from which is given in Table 1, this plant is only charged once daily. The number of charges daily depends on the magazine of the producer. If a producer has a magazine which works exactly as a base burner stove, it can be charged once every ten or eleven hours, and if run twenty-four hours, it needs charging only twice a day.

To clear up a point in regard to the consumption for a 10-hr. and a 24-hr. load, the question of consumption on a stand-over load depends entirely on the operator. If he leaves too large an opening on his purge pipe, he will burn up more coal on the stand-over period than he would if the stop valve is closed down so as to just keep the fire in condition. The difference in ratio between the consumption on a 10 or 12-hr. load and a 24-hr. load is the difference in the amount of coal the operator burns up in the stand-over period. The ordinary consumption of a good producer is approximately 1.1 lb. per h. p.-hr. with coal running at 12,000 b. t. u. per lb.

In regard to the Auto Press Co's plant, I am interested in the data from that, as I laid out the plant, built and installed it. While they were operating they had practically no trouble at all, but they did get a poor man in the engine room and he practically wrecked the engine through inattention.

The plant of which Mr. Thurston is engineer has been in use longer than stated by Mr. Ripley. It is within my personal knowledge that that plant was shut up at half-past six at night and ran through till seven o'clock the next morning day after day for 365 days in the year, and only once in six years did the plant stop through the closed period. I do not know of a single power plant, unless it is an electric motor, that can be left to run itself that way.

This paper is restricted to the Metropolitan district. We know that putting a gas plant, particularly a producer gas plant, into operation in the Metropolitan district, is one of considerable difficulty, owing to the restrictions imposed by the civic officials and the Underwriters' Association. These

two elements prevent the use of the producer gas plant in what might be called the Metropolitan districts.

HORACE G. H. TARR: For the last few years R. D. Wood & Co., with which concern I am connected, has gone into the field of larger producers than are discussed in the paper. I had the pleasure of reading a paper before the American Water Works Association perhaps five years ago at the meeting in Toronto, when I advocated a greater economy in the installation and operation of small waterworks plants. At that time I cited very strongly a plant we had built at Poughkeepsie. Anyone familiar with that plant will remember that the pumping cost has been brought down about 70 per cent. The plant has been running now for eight or ten years, there has never been any accident, and the plant has been running as smoothly as possible.

In observing the pumping plants of the country, gas power plants, very closely in the last ten years, I have found that the greatest difficulty is in the operation of them. A gas power plant is not wholly fool-proof. The difficulty with most of the gas plants in this country is just as the author has said—the man who cleans up, scrubs the floors, works in the shop, and does the handy work generally, is put in charge of the gas plant. Many times trouble is experienced with plants simply because they are not operated properly. They are operated, in most cases, by mechanics and not by engineers.

Up to a certain size, a gas power plant is beyond any question just as reliable as an automobile if it is properly built and properly run.

In the larger installations of gas engines, 500 or 600 h. p., we cannot figure out the costs as closely as we would like to do. In our own plant, where we are melting 200 or 300 tons of metal a day, we have five 300 h. p. engines running the plant. What it costs to run the engines we do not know, for the reason we dry our molds and do everything of that character with gas. In one foundry, we run three engines of 300 h. p. and in another foundry we run two engines of 300 h. p. We cannot tell our fuel costs. We have been running these engines for eight or ten years, and we never had a single breakdown that was of any consequence. A cutting-off of power would be a serious thing, and would cost us a good deal of money.

In our work, we must have something that is reliable, and our experience has proven to our satisfaction the absolute reliability of the gas engine. As to the relative cost, when you come to put in a large gas engine installation, you will find it will cost you about \$100 per h. p. A steam turbine installation will cost you a good deal less than half that. With several of our large installations, we are getting a horsepower-hour from one pound of coal, but the steam turbine, which costs half as much, will get down to less than 2 lb. of coal per h. p.-hr. These are the conditions in the gas producer business in the larger sizes. They do not apply to the small installations.

In a broad general way, Table 2 is exceedingly interesting, because it bears out almost exactly our own statistics. This remark applies to 500 h. p. installations.

It is no more fair to make a comparison of the gas plants of the present day with those of the past than to make a comparison between the automobiles now made with those of a few years ago. If a comparison is made of the plants

that have been installed within the last two or three years, the characteristics of the plant can be taken and a correct opinion formed as to whether or not a small installation, 500 h. p. or below, should be a gas or steam plant.

There have been some failures in plants in the last four or five years. In one case of failure of a gas plant in Florida, I found it was due to the fact that they could not get any cold water. The water used for cooling was absolutely warm, above 70 or 80 deg. Fahr. The water was drawn from a swamp, which was subjected to the rays of the sun, and serious difficulties were caused by it, showing that all conditions must be considered. If the latter is done, there is no question but that the gas plant is more, or quite as economical, as the steam plant.

E. RATHBUN: I know, to some extent, the amount of patience required to get answers out of power plant owners, and the author deserves a great deal of credit for what he has accomplished.

We have a very interesting producer gas pumping station in Toledo where our factories are situated. All the city water goes through the plant; it is the filtering plant, and there are three 15,000,000 gal. direct-connected 2-stage Wood & Co. pumps, and also four 500 h. p. producers, the total capacity of the engines being about 2,000 h. p. There is practically no reservoir capacity. The plant has been in operation about five years and has never been without water. They have a spare unit, and keep the pumps running all the while, that is, the low service station. The water is lifted by the pumps and put through the filter plant—the pumps are in a pit 45 ft. deep below the river level—and the water then gravitates to the high pressure city service, which is steam-operated, and, everything considered, the producer plant pumps the water for exactly half what the steam-operated plant does.

In regard to the list of plants in Table 1, one of the plants in Bayonne, N. J., now shut down, is missing. The original plant there consisted of an 80 h. p. two-cylinder engine, and a 100 h. p. three-cylinder engine, which were operated by the Southern Cotton Oil Co. This company has other plants, to the extent of four or five, of the same make, so that they are familiar with the apparatus. It seems the shut-down in this case was a matter of faulty attendance entirely.

The plant at Bayonne was in the same category as all the other plants, and it should have been as good as the J. M. Horton Ice Cream Co. plant or the Mergenthaler Linotype Co. plant, or any of the other plants,—there is no reason why they should not all be the same. There was the same chance at Bayonne for securing the proper kind of labor, for securing the proper coal and everything else, but the plant was not successful. It was shut down, and probably the reason was not so much on account of the difficulties of running the plant, but because the costs of repairs were high.

For comparison, consider the J. M. Horton Ice Cream Co. plant, the Swift & Co. plant, and the plant at Bayonne. The J. M. Horton Co. report their repairs not higher than they should be. The Swift & Co. plant report their repairs higher than they should be, and the Bayonne plant is shut down, apparently largely on account of excessive repairs. The ratio of the costs of repairs on these

plants in five years is as follows: J. M. Horton Ice Cream Co., 1, Swift & Co., 3, and the Bayonne plant, 10.

On the basis of h. p. years, the cost of repairs of the J. M. Horton Co. plant was about 30 cents per h. p. per year; the Swift & Co. plant, \$2 per h. p. per year from the time the plant had been in operation, which was excessive; and the plant in Bayonne, \$4 per h. p. per year. I went over to the Bayonne plant once, and found the small engine was running with the exhaust wide open and the governor down on the engine. That was one reason why this plant shut down.

There are many interesting points in this paper. It has been brought out here that Mr. Ripley has made a point of dealing with the small plant, not particularly, possibly, but in his report he has called attention to the small plant. If you look at the plants which have been thrown out, it is always the smaller plants.

As you get into the larger plants it is true that it is very much more difficult to get reliable information. When we stop and try to figure out and go over our list of plants and get some accurate information about something, as close as we are in touch with our own plants, we find that there are very few plants in connection with which we can get absolutely reliable information. True, the Horton Ice Cream Co. is one of the plants which keep the most accurate information of any we have on our books. There are plants where they have wattmeters and get the coal consumption per kw.-hr. Perhaps in the same plant they are doing some pumping, however, and drawing gas for that, so their data is not reliable. Some plants do not keep any records whatever, and they are liable to guess at the coal consumption and give erroneous results.

One point which has not been brought out in this discussion is that the oldest producer is only sixteen years old; that sixteen years practically represents the total development of the art, and it is quite a short time. It must also be remembered that this paper covers only a very limited area, and it is a feature of the gas producer business, as of all others, that it shifts from one part of the country to the other. In 1906 and 1907, within an area of 200 miles of New York City, we put in about 3,000 h. p. within about two years, and yet during the past year we had just one inquiry from Connecticut. Connecticut, logically, should be the best producer gas district in the whole country—there is good coal available there, and everything tends to good operation.

As regards later developments, it happens in this district there are no raw water ice plants, and in the last year and a half we have put in six raw water ice plants. That is a new development, and is particularly adapted to producer gas power plants. We have put in about 1500 to 2000 h. p. in the last year and a half on raw water ice plants. The development of the raw water ice business is also directly connected with compressing. In many of the compressing plants, being direct-connected to the engine, they drop the speed 15 per cent and increase the compressor speed almost 300 per cent, so that while it is true that the business has not been so active in this district, still it has been more active in other districts. Table 1 is not, of course, absolutely up to date; there have been new installations since its compilation, probably, not less than 1,000 h. p. which is not included in the table.

WILLIAM T. PRICE: The gas producer plants which have been put in in the past three or four years, which Captain Tarr has referred to, are much superior to those put in originally. It seems that the very best location for the producer gas plant is the place where there is, first, a steady load; second, good coal; third, where pea coal can be obtained. A great many producer plants are started up and it is recommended that they operate on buckwheat coal. A great number of the plants mentioned in this paper are operating on pea coal, in fact, nearly all of them. The last requirement, and most important of all, is that a good man be placed in charge of the station.

Mr. Ripley referred to one plant, which was an utter failure in its first location which, when put in a new location, was a pronounced success. That is quite common with the internal combustion engine, and the problems that come with the internal combustion engine plant of any kind seem to be about 80 per cent operating problems.

A good many comparisons are drawn in the paper between the producer gas engine and the steam engine. A few comparisons with oil engines might be of interest.

The power gas engine plant is guaranteed to operate under certain fuel consumption per h. p.-hr., but in a great many cases the fuel consumption, taken over a long period, is considerably different from the guaranteed fuel consumption. That is because, as Captain Tarr pointed out, the economy depends principally on skill in operating. The oil engine, on the other hand, seems to show practically the same economy over long periods of operation that it does under test conditions.

The early oil engines which were put out, of course, were not as perfect as those which are being made today, and troubles were experienced. It seems, though, that the oil engine of the present, and of the future, compares very well with the gas engine of the present, but this difference exists: that the oil engine is a complete power plant in itself, whereas with the gas engine it is necessary to have certain fuel-making equipments. In the oil engine the fuel comes in a condition ready to use, but with the power gas engine the fuel must be prepared. Therefore, it seems true that, in the present and in the future, whatever troubles come with the producer plant should be eliminated in the oil engine plant. The relative fuel economy depends on location.

There are places where coal is very cheap and oil expensive, and in those locations the producer gas plant finds a good field and the oil engine is handicapped. All down this Atlantic seaboard, however, in the case of plants of 300 h. p. and downward, the difference in fuel consumption is very slight—sometimes it is in favor of the oil engine and sometimes in favor of the producer plant, and we may say that it is more generally in favor of the producer plant, showing that the fuel consumption with the producer plant is slightly less than in the case of the oil engine plant along the Atlantic seaboard. Of course, in the West and Southwest, coal is very expensive, and coal producers have never proven successful, so the oil engine finds a broad field there.

Another advantage of the oil engine plant over the producer gas engine plant is the saving in the space occupied. Mr. Ripley has given an intensely interesting study of data, and with close attention considerable profit should be derived from it.

INDUSTRIAL SAFETY AND PRINCIPLES OF MANAGEMENT

BY W. P. BARBA, PHILADELPHIA, PA.

Member of the Society

THE matter of accident prevention has come to be considered as a point vital to the success of any business—through the operation of reasons, economic, humanitarian and sociological. Only a few years ago, say ten years, little was heard in this country of more than desultory efforts to minimize the waste of human effort through accidents. Now the slogan *Safety First* has been given widespread currency, and has lately been improved by coupling with it another, without which the first is really of little value, hence we now hear *Safety First—Safety Always*.

It requires no detailed presentation to make manifest the waste to the world of productive power through the suspension from their daily labor of men injured therein, of the consumption of materials without the corresponding production which normally would result therefrom—of the real suffering, both of the injured man and those dependent upon him, or of the investment laid aside and idle with every man injured. As part of a study of the principles of management (which should accompany the technical education of every man called to work amongst his fellows) much too little attention is given to the subject of methods of employing labor, both trained and untrained, and too little weight is laid upon the cost of training *any* new employee into the duties for which he is hired. Few realize that each man hired into a plant is the subject of investment for quite a time before he is sufficiently trained to the work he is to perform as to return a profit. It is probable that a study of the subject would produce a figure of \$150.00 average of investment in each man before he becomes productive.

So when true principles of management are but little understood and rarely taught, it is customary to witness many discharges as corrective of offenses which are perhaps trivial at best, but which discharges in any case only act as correctives for the benefit of the employer with whom the discharged workman may next engage for employment. A better way, for instance, is to call up the man, convict him to his own satisfaction and yours, of the wrongdoing in question, and then and there apply the punishment which should correct the offense, using means which will inure to the benefit of the employee as well as the employer. This can be effected by lay-off or fine; discharge should be rare, and only for major offenses. Fines should be used most often in preference to either of the other more usual means. Fines should be laid with great care for the proper amount needed to effect the corrective, and a relatively small sum usually is sufficient. In no case should fines accrue to the benefit of the company, this having a very disturbing effect upon the value of the corrective, but fines in all cases, both for spoiled work and for discipline, should be converted into a fund for the benefit of the whole body of workers. Some mutual benefit plan, such as is now happily established in most up-to-date works, should receive the results of all fines. The result is then doubly beneficial, and has a balmy effect which removes all soreness and sense of *personal* injury from the transaction.

Referring again to the loss of investment from removal of trained men from production by discharge, let us also look at this loss through *physical* injury, and especially those arising from preventable causes. It is, of course, plain that the investment loss through injury can become a permanent loss of producing power, the loss of investment causing the employer to suffer, and the loss of producing power causing the injured man to suffer permanently, as well as through the physical pain he bears, meanwhile; his producing power and income reduced or gone, his expenses continue even on a reduced scale, his mental condition is much disturbed and he wonders what can be done, and so the rapid but all too slow growth of the safety movement, the liability and compensation laws, the preventive measures, but most powerful of all, and as yet but little developed, the education of every person engaged or even interested in industry, to the end that all preventives be used both *without* and *within* the person of the operator subject to injury.

Figures compiled during a term of years point most strongly to the lack of proper education as the prime cause of injury—loss of productive power, and all the attendants of this condition. Hence, industrial safety and sound principles of management are without doubt most closely bound together, and cannot with success be considered apart. Commissioner John Price Jackson, of the Department of Labor and Industry of Pennsylvania, has shown in dollars and cents just what the large number of accidents that are occurring in the industries of the State, are costing the workers. He has not figured what they cost the employers.

During 1914 accidents cost employers in a score or more of the larger industries in Pennsylvania the sum of \$1,048,503.96, which total is computed on the daily wage. There were 38,126 men thrown out of work and each of these men lost on the average \$27.50. The accidents from which Commissioner Jackson has computed the figures do not include those reported to the State Department of Mines or the Public Service Commission. The report shows that about one man in every 28 lost time because of accidents, as there were 1,086,508 employees in the industries from which statistics were gathered. The average daily wage was \$2.45 and the total number of working days lost was 426,824.

This brief report gives one an idea of the extent to which accident prevention may go, the aggregate for this State only being so large as to appall one, and still does not include mining risks that are notoriously great. Indeed, most of the opposition which was disclosed in an organized way to the enactment of a workmen's compensation act has been from the smaller operators of mines, whose whole capital could be annihilated by the liabilities arising from one accident on a small property.

From the operation of these causes, motives and products alone, there has within the last eight years, come into being a general safety movement, looking more toward the possibilities of prevention than ever before. Out of all the upward striving of humanity toward better things and better conditions comes a new principle; namely, that a trade should bear the charges and costs of its casualties, and from

Presented at the Philadelphia local section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, on Nov. 23, 1915.

this, the employers' liability and workmen's compensation movements have gained much force. Rarely has there come before the public a movement involving so-called capital and labor, but in reality employer and employed, which has met with such complete support from both sides. But there are no "sides"—the interests of *all* employed in the world's productive work are entirely identical. To enlarge upon this thought, for it is one of the links attached to the title of this paper, these two, together with their many links, are inseparable—in practical everyday work, just like a graphically expressed formula in organic chemistry.

It will have been noticed from these prefatory remarks that this connection is quite clear. One who is charged by his owners with operating a large manufacturing plant has as his first practical concern, the securing and retaining, as well as maintaining in good efficient condition, a well satisfied body of workmen, contented, well paid, and their physical condition well in hand.

After this the managing executive may take up his financing, his raw materials, manufacturing methods, selling organization, etc., but no manufacturer can possibly succeed without this satisfied body of operating workmen—fellow employees as just outlined—to secure and maintain this condition is a prerequisite to any further success.

The economic as well as the social side of this problem must be just as carefully looked after, now that Pennsylvania has a workmen's compensation act, the twenty-fourth in the United States, which country followed quite a long way behind both Germany and England. No longer will industrial safety be thought a tad, no longer will the courts be filled with cases crying for just relief, no more will the cheap lawyer haunt the hospitals to prey vulture-like upon the unfortunate. Each trade is to bear its share of the cost of its casualties, and the ultimate consumer will pay the bill. All this is exactly as it should be, the only danger lying in the chance, a real danger too, of the whole game being absorbed into some form of political spoils, which God forbid.

Much is being said and printed about foreign trade, foreign competition, foreign methods, and many have objected that the securing of this foreign trade in normal times was difficult, due to the difference in labor conditions, rates of pay, etc. It is very interesting to note that in 1885, Germany established compensation measures, followed by England in 1891, so that our trade abroad is not menaced by the adoption here of these plans for workmen's compensation. On the contrary, we have lagged so far behind these stiff competitors, in these particular matters, as to cause unfavorable criticism of us by those who know.

Now when such compensation acts are generally in force, each employer will be placed automatically on piece work to make his plant *safe*; and the penalty for failure to achieve safety of equipment will be very great. There are, however, other features in the case: present and proposed laws provide greater compensation for a man with a family than a lone bachelor without dependents, some laws providing compensation for the grandfather of a man injured, when dependent. The natural result will be to select for employment men who offer the lowest risk, both as to compensation penalties and as to physical condition of the applicant, which condition exactly reflects chances of injury, and consequently, the rate of risk. The compulsory insurance laws of Great Britain, placed in operation in 1912, immediately

resulted in selection of employees whose rate of risk was the lowest, and thousands of perfectly good workpeople were turned adrift for this reason.

This is one of the consequential results our legislators and regulators should consider most carefully. There will inevitably result, a careful selection of the best insurance risks, and defectives of all kinds will find it most difficult to obtain and retain employment. A defective in this sense may be a man physically unfit, incipient hernia, a tendency to joint dislocation, etc. He may be defective in the sense that he just cannot keep out of trouble, and this kind of a man soon cannot keep himself in a job. He will be *selected* to be always out of a job, until he learns to *think* enough to keep himself from unnecessary injury. Study of the figures showing frequency of accident to the individual no matter where working, inevitably searches out such men, and then the employer must move the man, either to another job or else *out*, both ways meaning a loss of investment, production and earning power. Again education, both of the man and his employer, most necessarily his immediate foreman, is needed and just how best to supply the lack is a task worthy the best mind in your employ.

The works with which the author is intimately associated, has for years made a careful physical examination of each man offering for employment, having in mind his condition with reference to health, present and potential, his record as to previous injuries and their results, his eyesight, hearing and whatever condition will affect his value both as an individual and as affecting his fellow workmen.

At one works there were offered for employment, practically hired, then turned over to the physicians for this examination 2,569 men during the year 1913; of these 391, or 20 per cent were rejected for various reasons. Of these 391 rejected, 285, or 75 per cent, were rejected for venereal diseases and consequences, it being deemed most wise to turn loose a man possibly syphilitic amongst presumably clean fellow workers. Of course, a man may pass inspection upon employment, and then find his health go down. He may become the subject of venereal disorder, or some other form of communicable disease. The answer for this is the growing need for periodical examination of each individual worker, and his elimination when his risk becomes too great. This periodical examination of employees has been undertaken to much too small an extent, and needs attention and developing. The benefits are numerous, the first and chief being the aid and assistance to full recovery, and checking in advance of disease which a man unconsciously fights off until he drops—mastered. Beaten by exposure to a blizzard or heavy storm when in a reduced condition, many a good man is lost, who, by a regular, even though cursory, examination might have been saved through timely catelting, checking and conqering, through advice and aid, of an ailment creeping up on a man almost without his knowledge of anything going wrong. In this connection arises the demand, a just one, for some form of insurance, preferably mutual, and upon a sliding scale, according to the risk offered by each man. This is but one of the many problems each executive is going to face in the future handling of employees' matters.

When a man is hired, he should be taken to his foreman for careful instruction in his duties, its dangers and their safeguards pointed out, and every effort made to prevent

the new employee from becoming worse than a normal risk. As one concrete illustration of this, in a certain large works much fuel oil is used for heating purposes, and a comprehensive system of storage and distribution is installed. Leakage is impossible to entirely prevent, and numerous explosions and small fires have occurred. It is necessary at times to descend into the pits in which the apparatus is placed, and the explosive fumes of oil and air are frequently present; steam pipes (not air—because of the danger of air) are rigged in all such places and at stated intervals the steam is sent through these chambers entirely and safely displacing all noxious gases.

Again, the burners for fuel oil are merely a combination of jets and valves—some of the jets embodying the injector principle. Each man who is called upon to work with this apparatus is taken into the bureau of Safety First by his foreman, and with the safety engineer (a high priced executive) is taken through a course in his particular oil burning apparatus. The collected unit is there, it is disassembled and reassembled by the man, and a partly cut-out section is shown, so that all the functions of the system are fully understood by the workman. Since the introduction of this system of instruction, the number of burns and fires from ignorant handling has been very much reduced. It is impossible, however, entirely to eliminate the accidents from careless handling. Here, as elsewhere, the adage "Familiarity breeds contempt" is true, and it would be easy to multiply concrete illustrations of this statement.

In 1907, in a nearby large works, the safety movement was given a real start, by the appointment of a safety officer, whose whole duty was to report hazardous conditions of plant and equipment and see that the conditions were corrected. It has lately been more generally recognized as the function of the factory inspector of the State to keep every manufacturing establishment in a safe condition, so far as equipment, etc., is concerned. The present incumbent in Pennsylvania, Dr. John Price Jackson, has given real value to this function for the first time, but even he, up-to-date and progressive as he is, recognizes that the correct way is to make each factory safe automatically by having liability laws which properly penalize the lax employers.

The attempt of 1907 to effect safety of equipment by the appointment of a safety officer and his staff, in the works mentioned, was soon superseded by a plan to make the worker himself feel his share of the responsibility, and a committee of 70 men was chosen from among the employees, there being upward of 5,000 employees. These men were always on duty while regularly working and seven of them were chosen each week and with the safety engineer gave up a whole day in the company's time and pay to actual examination of conditions of plant and equipment. Their recommendations were given priority by heads of departments and the works were soon found in such good physical shape that the committees had little or nothing more to report.

The number of accidents was, of course, reduced, but not to a point which was thought commensurate with the efforts put forth. During all of this time (five years) careful study and analysis was given the daily accident reports, with the result that they soon segregated into three groups:

1. Hazards of occupation
2. Hazards due to faulty equipment

3. Hazards due to personal carelessness and disregard of safety appliances.

These regularly occurred in almost unchanging proportions, even though the sum total went steadily downward:

The first class—Hazards of occupation, 24 per cent.

The second—Faulty equipment, 3 per cent.

The third—Carelessness and neglect, 73 per cent.

This large proportion, 73 per cent, is purely a result of the operation of the personal equation, and, at once suggested itself as the point of attack.

To meet this a total change of programme was inaugurated. The plant was divided into seventeen distinct units or geographical districts and a committee of three was appointed in each for a term of two months. A datum line for each district was established from history which showed the frequency of accidents in each district. The figures were worked out in units per one hundred men employed for the period of two months, thus affording easy comparison.

The task set was for each district to equal or beat its previous record. No district was set against another, its record being wholly within itself. This is a vital point. Each sixty days' record is merged into the previous total and thus a new record automatically set. For a committee which equalled or beat its district record during the committee's sixty-day term, there was established for each man a cash prize of a ten dollar gold piece, or \$30.00 for each winning district each sixty days (incidentally the amount thus paid during the year 1914 was \$3,200.00, and no sum was ever more cheerfully paid out). In addition, the committee which made the greatest improvement upon its own record was, each period, granted a double prize, or \$20.00 to each of the three men.

The experience of the first year was that out of the seventeen districts there were paid prizes all the way from four up to sixteen districts, the four being midway in the year, and the treatment applied by the management when this low score occurred, brought the score right up, so that at the last period fourteen sets of prizes were paid. The personnel of these committees is changed each period so that the experience gained is accumulated by a large number of men.

The treatment in this case was simply for the general manager to talk to the assembly of the men later referred to, and point out, from knowledge of the accidents occurring during the period when low scores were made, how greater vigilance, less laxness, more attention to the men seen to take hazards carelessly, would result in better scores, more gold pieces, less suffering, to risk of which each of the whole number of employees is subject, whenever vigilance in these particulars is relaxed.

There is also a collateral advantage which is a large part of the value of this new scheme. The management hires a large and convenient hall for a meeting place, provides cigars and light refreshments, invites all the men the hall will contain (about 400) and makes a public occasion of the presenting of the prizes. A free discussion of methods and experience is had, and from 8 o'clock to 9:30 an evening is spent which is most profitable in every way. Stimulation is given the safety movement, the managers are all there, and a great feeling of the community of interest of all concerned is engendered. The spirit of full coöperation is established and fostered, a better and closer acquaintance is had on all sides, and the whole effect is most beneficial.

The net result in figures is curious and interesting. By an accident is meant the state requirement or definition—that a man is away from his work more than two days. The number of accidents during the year just closed was reduced by 59 per cent, the three above classes being represented by 26.8 per cent, 2.23 per cent and 71 per cent, clearly showing that there is still more work to be done in fully bringing home to the individual his personal share in the responsibility for his injury.

This responsibility is going to be more closely brought home under compensation acts, since it will mean the elimination of men who are thus injured through their own fault too frequently; these men will be compelled to seek other employment. It then becomes a nice point of judgment for the management to determine whether its investment in such a man, i. e., his trained capacity for his work, is a sufficient offset against his increased risk, due to his propensity for acquiring injuries to an undue degree. Some of the compensation laws refuse a man any payment if it be shown that he was injured by *his own act* for the purpose of going on the benefit list. This provision and the one denying benefit for the first *fourteen days* are about the only safeguards the employer has against unjust claims for payments.

Reverting to the system suggested of avoiding discharge losses through conviction and fines, the proper channel for restoring fines upon delinquents to circulation through the whole mass of employees is—the recognized need of caring in some way for the reliable employees unavoidably injured slightly, and returning to work within the 14 days exemption period provided by recent compensation laws.

A fund could be provided, augmented by the company, especially so in the case of larger employers, this fund to be administered by a mixed board of employees, and a small measure of financial relief afforded the unfortunates who recover within 14 days. This period, designed by framers of the acts to prevent malingering, does not altogether effect this, and meanwhile works a real hardship on many worthy men whose needs are such that the uncompensated loss of *any* days becomes a matter of concern.

If ever there was a subject fit for Federal instead of State legislation, it is this one of liability and compensation. Fifty-eight States working each alone may produce such wide diversity of legislation as really to put neighboring States into competition for both manufacturers and for workmen. When John P. Neill was Federal Commissioner of Labor he worked assiduously to secure uniform State legislation on this subject because there were statutory difficulties in the way of a Federal act. This leaves it up to the several States where too often a subject of this magnitude is taken up by untrained and uninformed legislators who can,

quite possibly, be swept into ill-considered action by a wave of hysterical outcry from the newspapers, professional labor leaders, and publicists who treat a situation academically and without close knowledge of the problem.

With especial reference to the Pennsylvania law just enacted, it is fine to recall how this law was prepared. Begun under Governor Tener by a board of broad expert business men, thrown out by the legislature of 1913, brought up again by a Governor fearless of criticism, worked out modernly upon the basis of the original commission's draft, the Pennsylvania law is, generally speaking, satisfactory to all groups, and there is in it opportunity to coöperate fully, to protect those dependent upon their labor for daily bread, automatic incentive to clean, healthful surroundings, care in safeguarding equipment, and all concerned are compelled to do their utmost to achieve the blessed result desired.

Any employer, or rather fellow employee, who shall disregard the plain common sense demands for a legitimate, well considered scheme for automatic compensation for every injury not wilfully incurred, is not alive to his business, to his duties, to his men or to his stockholders, nor to his duties to the progress of humanity at large.

It is the speaker's firm conviction that the so-called *industrial unrest* is wholly preventable, is due chiefly to lack of understanding of the problem—lack of patient working in full cooperation with all concerned, and the result of following sound principles with policies based thereon is certain to prevent unrest such as has been all too frequent from just such causes.

The years in the immediate future will be largely occupied with the care and handling of just such problems as are here presented, and if anything said here gives a line to take hold of and follow, the author will be more than glad of the opportunity to discuss a matter so large as that of the subject presented. In pointing out the dangers of haste in enacting such legislation, all right thinking people are urged to work for the passage of such laws as will compel the lax, careless, or unwilling employers to secure the cooperation toward safety of workers whose livelihood, and lives, are in the hands of those who pay wages, and as before mentioned should find it a cheerful duty to work toward the securing through coöperative effort, of the maximum of safety, comfort and happiness among all grades of employees. Only thus will the work of the world be furthered. Only thus will there be removed from among us strife, discord, class distinction, unions and non-unions, and there will surely come into industrial life, the big rewards which result from careful thought along lines which go to promote full cooperation amongst those called to do the work of the world.

SAN FRANCISCO MEETING

THE five papers presented at the two sessions of the September meeting of the Society held at San Francisco, September 16 and 17, in connection with the Panama-Pacific International Exposition and the International Engineering Congress, were published in the October and November issues of The Journal. In this issue is published the Discussion that followed the presentation of the papers. That upon the paper by G. L. Bayley, is of particular interest for its application to the varied construction problems at the Exposition, and that upon the paper by W. H. Adams, in view of the development of the Diesel engine on the Pacific Coast.

DISCUSSION OF PAPERS AT SAN FRANCISCO MEETING

PAPER BY G. L. BAYLEY

G. L. BAYLEY, in presenting his paper on the Engineering Features of the Panama-Pacific International Exposition, dwelt upon features of interest supplementing the text of his paper, as given in the following account:

Mr. Bayley, referring to the planning of construction methods and preparing estimates and load curves for the Panama-Pacific International Exposition, said they naturally wanted to be guided by data relative to previous expositions and had searches made for such data, even in the Congressional Library. To their astonishment, little real information was available. Such an important item as the maximum load at the St. Louis Exposition was finally found in Engineering (London). The load was 13,500 kw. All the various reports of that exposition gave full descriptions of the great power load, how many thousand horse power was being utilized, etc., but the maximum load and diversity factor, or any other elements which would have been a guide in their case, were not available. It is impossible from any reports to find the amount of water used at previous expositions; any records, where they exist, are not available.

When they started in to build the Panama-Pacific International Exposition, Mr. Bayley said that if they had only known half as much as they know now they could have saved many thousands of dollars. Now that they have collected a great deal of information, much of which is of real value, they intend putting it on file in the Engineering Society's Library in New York so that it will be available in the future.

The area occupied by the main group of the Exposition palaces, which includes eight large buildings, was about 12 ft. under water when they started operations. Mr. Bayley said. So at the very inception of the work, they had a problem of considerable magnitude. The filling in was performed by the aid of suction dredgers, and in that connection they followed out a procedure which he did not think was unusual, although it has attracted some attention, that is, getting rid of the soft bottom by displacement of the heavier material. The discharge pipes were so located that the heavy sand kept forcing the ooze and mud ahead of it and out through the sluice gates. Occasionally, in order to stir up that material, they would run the dredgers without pumping any sand. The result has been a very solid compact fill, which, however, has been settling regularly as was expected. The large buildings were all placed on piling, and the amount of piling is somewhat tremendous. He conveyed some idea by saying that if the piles were all stood on

end, they would form a column 125 miles long, and if one stops to consider the cost of driving 125 miles of piles, one realizes the initial work on hand.

Before starting the work of pile-driving, Mr. Bayley said a number of experiments were made to find out the load which would be permissible, and these experiments proved to be exceedingly valuable, not only from an engineering point of view in determining the amount of load that a pile would stand, but as to the exact length of cut-off of the various piles, so that when a contractor was called in to take a contract for piling, he knew exactly, within 6 inches almost, the length of piles over the area. In that way they obtained close bids, because the contractor knew that he could use piles of 35 or 40 ft. and so on, and he would not have a lot of other lengths cut off which could not be used.

They found, in driving the test piling, that the fill itself imposed a considerable load on the piles. One can realize that from the suction of the fill on the pile, and the fact that the fill was settling. A portion of the fill was over an existing sand bank, under which lay a stratum of clay. Following the standard procedure, they would have driven into that clay and probably have used a 40 ft. pile. They found by experiment that they could drive into about 12 ft. of sand but not puncture through it, and get practically the same bearing value with those piles. The result was that they used 12 ft. piles instead of 40 ft. If that were converted into thousands of dollars it would be a considerable amount, all of which indicates the advantage of proceeding with exact knowledge of the conditions as they exist, and which can only be determined by experiment; although they spent probably \$6,000 in getting this information, it was well worth many times that amount.

Mr. Bayley then referred to the question of structural design of the Exposition, most of the structures being timber ones. In the last fifteen or twenty years very little advancement had been made in frame structures, because steel had supplanted the use of timber very largely, and frame structures have been mostly used only by sawmills and similar activities. In the instance of this Exposition, wood was by far the cheaper material to use, and in addition, could be gotten very readily, whereas there was an element of time in getting deliveries of steel. That knowledge which had been secured to engineering by the steel practice has been applied with rare intelligence to the design of the wooden structures of the Exposition. In the Machinery Building, for instance, there is some very interesting frame work. Shear pins are used effectively, and the enormous roof structure really seems to be very light.

Some very valuable data was secured by testing out full sized joints, Mr. Bayley said, and, strange as it may seem, with a shear pin made of a certain Hawaiian wood, a greater

strength was developed in the joints than if the pin were made of solid steel. A technical paper has been written on this particular subject, and those who may be confronted with a problem in timber design might well consult this. With the exception of the Tower of Jewels and the Palace of Fine Arts, the buildings are all timber structures, and all are carried on pile foundations, except a certain one or two, which are on spread structures.

The Tower of Jewels is a most interesting example of engineering. This was built up as a pyramid, and as originally designed the tower was to contain the administration office and presented a very serious problem of construction. That idea was abandoned, however, and the weight of the steel was reduced by half; in other words, the tower was framed up for the usual load of floors, after the same type of construction that is used in office buildings. By adopting the pyramid form, and framing on the various platforms of timber, the cost of construction of the tower was considerably reduced.

Mr. Bayley pointed out that the Exposition is more or less of a dome city. Dome construction is somewhat unusual, and many interesting problems were solved in connection with the various domes that are at the Exposition. Doubtless, the most interesting dome is that of the Palace of Horticulture, which has the largest spherical dome in the world. It is 152 ft. in diameter and has a height of 185 ft. To show the difference in results that may be obtained by starting on different suppositions, one engineer designed that dome as a 3 in. arch; the depth of the ribs was 6 ft., and the angles used were six by six. Another engineer designed it as a through dome, with ribs 4 ft. deep, and angles four by four. Doubtless, the former engineer's calculations checked out all right, but by adopting the latter's figures, the dome was built with about half the amount of steel and is a perfectly rigid and stable structure.

The method of erecting this dome was to take two ribs, form them together on the ground and then hoist them. A gin pole was used in the centre to carry the ring and hold it up while a third rib was put in, when of course, the structure was comparatively stable. After that, one rib was put in at a time until the dome was completed. The methods used for putting up these domes were very interesting. Apparently, no two contractors agreed as to the best method, and many ingenious means were employed.

The method of dome framing was rather original, and the framing of the great half domes on the west side of the Palaces of Food Products and Education were very interesting examples. The Palace of Fine Arts is a building which is semicircular in plan, and, of course, had to be free from all columns; for that purpose the three-hinge steel arch construction was used.

At the start, Mr. Bayley said, rules were made governing all structural work; in these rules the allowable load stresses and other designing data were established, with the result that the designs were consistent throughout. In a work of this magnitude, it seemed very essential that each man's work should agree with the work done by every one else. In other words, consistency on the part of each individual designing engineer, in such assumptions as factors of safety and unit stresses was desirable. Not only did the Exposition have a large corps of designers of its own, but, owing to the press of work and the shortness of time, some outside engineers

were employed and these received the same set of rules to govern their designs.

Regarding the sewer system, Mr. Bayley said there were no especially difficult problems there, except that they had to lay the sewers bearing in mind that the ground was settling, so that wherever they had connections from buildings, they had to be flexible connections, which called for a special design. At the State and Foreign sites, owing to the flat grade, and the Exposition grade being only a few feet above high water, it was necessary to put in some pumps, drain the sewage towards one central point and pump it to the Bay.

Under the head of transportation, Mr. Bayley said their greatest problem was that of handling lumber. It was really quite an inspiring sight there at times to see six or eight vessels all piling lumber down, but the large volume of work was well cared for by the simple method of using lumber trucks and horses.

Possibly no problem in connection with an exposition, Mr. Bayley said, is more serious than that of carrying on building construction and trying to maintain roads at the same time, and especially as so much work is usually done during the wet season. Of course, at San Francisco they worked all the year and very few days were lost. Plank roads were used throughout to great advantage and while probably \$40,000 or more was spent for those planks, the expenditure was well justified, because they could very rapidly change a road in order to get material in for the various buildings.

The plank roads were further useful at the time they came to build the permanent roads. In constructing the permanent roads, they found a very satisfactory method to be to build half the road and pave it, in the meantime maintaining traffic over the other half by means of planks. Then as soon as the half was paved, they would move the planks onto the paved half and switch the traffic onto the planked side and build the other half of the permanent road.

Rigid traffic rules were necessary, Mr. Bayley said. Teams were obliged to come in at a certain point and go out at a certain point; otherwise there would have been a hopeless jumble. Those who have not seen the building of an exposition, he said, can hardly conceive the amount of pre-exposition traffic, particularly just before the opening day, when teams are coming in with exhibits. Exhibitors are habitually late, and they all come in at the last minute and work all day long and into the night making deliveries, and, unless a good scheme has been well thought out to cope with the situation, confusion is liable to reign.

The Exposition undertook to deliver exhibits directly on the exhibit space. This was quite a departure in exposition traffic, but one which has been very satisfactory to exhibitors. In previous instances, the railroad terminated at some point in the Exposition grounds and then the exhibitor had to make arrangements with some local concern to get his exhibits moved in. Here they made a terminal rate so that an exhibitor, say, in Philadelphia, could get from the Pennsylvania Railroad the exact cost of transporting his exhibit and delivering it right to his space in the building it was to occupy.

As they undertook that obligation, Mr. Bayley said it was essential that they make some arrangement to take care of the situation. They ran spur tracks into all the buildings, with unloading platforms and then made use of

the transveyor, which is a small truck with a mechanical arrangement for use in connection with special platforms, and with that they handled the situation without any congestion. In the same connection they had a number of storage battery industrial trucks and at times these were used to haul the transveyors. In the Machinery Building were installed overhead cranes.

Attention may be called to the excellent manner in which visitors are transported about the grounds. Those who were at St. Louis will probably remember that they had the automobile busses, but they were very hard to enter and alight from. Here they had the so-called Fadji train.

In the matter of fire protection, Mr. Bayley claimed that no exposition had a fire protection comparable with that installed at this one, and it may safely be said that few communities enjoy an equal security against fire. In addition to the high pressure distribution mains, there was installed a sprinkling system in all of the eight buildings of the main group. In the Machinery Building it was not thought that the sprinkler system would be very effective, owing to the great height of the roof.

The next matter of great importance was that of water supply. In this connection, it was found that the local water company could not supply them with water, and they were confronted with the problem of supplying about two million gallons a day.

Few expositions have ever had an adequate supply of gas. He thought it was safe to say this was the first Exposition that had gas at every portion of the grounds and that in adequate supply. Gas had been a great factor in many respects. Almost all of the cooking in the Exposition grounds was done by gas. In order to cover a square mile of area at a reasonable cost, the high pressure gas system was used. Gas is distributed at a pressure of about 80 lb., and the pressure is reduced by means of governors at the various points of use.

Regarding the gas lighting of the streets, in the State and Foreign sites, there was an installation of over 250 high pressure gas lamps, which he thought was easily the largest in the United States and also one of a very few. Here can be seen the great possibilities in high pressure gas lighting. The gas mains were all welded by means of the oxy-acetylene process.

PAPER BY G. W. DICKIE

G. W. DICKIE, in presenting his paper upon Mechanical Engineering at the Panama-Pacific International Exposition, said that in some respects this Panama-Pacific International Exposition differed from all the other international expositions that have been held, in that it represented a changing condition in mechanics. There were no steam engines at this Exposition with the exception, perhaps, of one or two—none of them in operation, and none of any size worthy to be considered as monumental. There was one 500 h. p. double cylinder sawmill engine, which was a very plain piece of work; steam was carried probably seven-eighths of the stroke. But it was worthy of mention as the sawmill engine is built to consume all the power derived from burning all the sawdust the mill makes, and if it cannot do that it is not a success. In order to do that it must not be economical in the use of steam.

DISCUSSION

A. STRICK said that, coming from Pittsburgh, it struck him very forcibly to hear that wood was mostly used in the construction of these buildings. Ordinarily it is said: "Wood is not in order any more. Steel is cheaper and stronger." But here it was found that it is more economical to use wood instead of steel, and he understood that Mr. Bayley had made a very thorough study of it, applying engineering principles. But what struck him most of all, was the foresight exhibited in not only following financial views in getting the buildings installed cheaply, but in protecting them by a sprinkler system for fire protection, such as has not been used before in such magnitude.

H. G. REIST asked whether the same thing would hold today with the Panama Canal opened; that is, whether a large part of the difference between the use of steel and timber was not due to the transportation of steel.

A MEMBER asked Mr. Bayley how they determined in the beginning the approximate floor space required for the different exhibits.

JOHN R. FREEMAN, referring to the use of wood rather than steel in the framework of the Exposition, called attention to the duty of the interior architect. Even so good an authority as Newhouse has said that we have to compliment engineers for knowing how to make the interior of a building. He had had the pleasure of handling a great many of these expositions, all the way from that of Paris of 26 years ago to those in Chicago and St. Louis, Portland and others, and he had never yet been in any large building for exposition purposes of a temporary character where the framework was arranged so that it was fancy and beautiful until he came to this Exposition here. He thought a compliment should be handed to the men who designed the interiors of those buildings and worked those trusses out of lumber at \$13 a thousand and made them beautiful.

W. C. LINDEMANN asked if in the consideration of the salvage on the Fair buildings, a definite figure was arrived at, and if so, how it was calculated. In figuring the cost of work, of course, the salvage value has a considerable effect on what the ultimate work is going to be.

A MEMBER asked Mr. Bayley if they have anticipated any system or method by which the salvage on the Exposition installation may be decided on when the Exposition is closed.

SELBY HAAR, referring to the estimate that was made of the electric load as a load factor of thirty per cent, asked whether that estimate came pretty close to what was actually right.

H. G. REIST called attention to the beauty of these made-to-order cities at the various World's Fair Expositions. This one, is particularly beautiful, both in the individual buildings and in the grouping of the buildings, and it would seem strange that in the building of these temporary cities such beautiful results can be achieved, but in building permanent cities they are built very much haphazard. He felt that it is largely up to the engineering profession to try to make a change so that our permanent cities will be as beautiful as our temporary ones.

G. W. DICKIE, referring to the lack of data in connection with exposition building which was a great handicap to them, said he was sorry that Mr. Bayley did not discover the stupendous report of James Burge, as British Commissioner at the Chicago Exposition, in which there is an immense amount of information. The buildings are all tabulated there as to load and the foundations and also cost of building per cubic yard and foot and square foot of floor, etc.—a very interesting gathering of data, that he thought had been used very largely in expositions, especially in Europe.

MR. BAYLEY, in answer to Mr. Stucki and Mr. Reist, said it was largely a question of setting the height of the buildings when the buildings were being designed. About two and a half to three years before the Exposition opened, there were some grave doubts whether the Panama Canal would be opened at all; in fact some were afraid the Exposition would be completed before the Canal, and at the time there were no assurances whatever that they could get required delivery of steel and also the expense was very much higher. Of course, here they had the timber, and the most splendid timber, delivered for about \$13 a thousand and steel didn't have much show. It is largely a matter of cost, and has to be figured both ways—whether the steel can be gotten for a less price. He was very sure that wood would be the cheapest there in any event.

Replying to the question concerning floor space required, Mr. Bayley said exposition building goes by habit, so far as he could ascertain, and he tried to find out how much space was assigned at previous expositions for a certain classification. They had to depend very largely upon the recommendation of the division of exhibits; in fact, that division really specified the amount of space that would be set aside, and it was their thought to divide products.

In reply to the question concerning determination of salvage, Mr. Bayley stated that the salvage value is just a matter of opinion. He believed that in the Western market, they could get rid of the lumber. One would be astonished to know how much second-hand lumber is used on the West coast. The mine people use it for timber work, and it is used for bridges, all sorts of temporary purposes and a great deal of permanent work. Of course, in the question of the selection of timber the salvage practically was not so important. In other kinds of salvage they knew pretty well. For instance, waterproof wire has a good salvage value because the insulation can be burned off readily and there is the copper. With a conduit, however, there is no salvage value and they wanted the cheapest possible initial cost.

In reply to the further question concerning salvage when the Exposition is closed, Mr. Bayley said he was then writing the contract for the sale of the Exposition, as a set of specifications. They would solicit bids to buy the Exposition outright and undertake the salvage, as they did not care to do the salvage themselves. They were satisfied with having built and operated the Exposition, and want to sell it for a lump sum. He said there was a very large amount that was not included, as they were singularly fortunate in getting a very large amount of material on a rental basis, which in fact, effected a very large saving, aggregating almost a million dollars.

In answer to the question of Mr. Haar, Mr. Bayley replied that the load factor of thirty per cent. was so close that it

might be said they had advance information; it was a little over 29 per cent.

In reply to the question raised as to why we can build something temporary and make it a unified whole and something of beauty, whereas we fall down in such a remarkable manner when we start to build permanently, Mr. Bayley said he thought the answer was not difficult to see, and it is that they had concentrated control. Take, for instance, the case that so often results in developing civic centers and other monumental groups; one regime will take hold and they will work out a scheme, somebody else will come along a little later, and then another architect will probably succeed him. He referred to a wonderful instance of that in New York in one of the cathedrals; each one of the architects had his own individual ideas. Here, at the Exposition, there is no one man who dominated the architectural situation, but there was an architectural commission. The idea of the block plan made it essential that they all work together. There are different types of architecture, but there is no conflict, because one cannot see three courts at once. One may go around that whole area, the whole length of those buildings, and it was all the work of one man. The result is continuity and harmony. Each man would express his individuality, which, he thought, was really the success of the Exposition; it was due to the fact that they started with a scheme which necessitated harmony; that is, they could not very well go astray, so long as it was decided to have one man, or one element.

PAPERS BY W. H. ADAMS AND A. H. GOLDINGHAM

DISCUSSION

H. R. SETZ called attention to two points of especial interest to all; one is that mentioned in the last paragraph of Mr. Adams' paper, par. 65:

The item of life of the Diesel engine is open for discussion, but no one can yet say definitely what the life of the Diesel engine, properly taken care of, is going to be, as none of our successful plants have been in operation long enough to give the answer.

In order to get an answer, we will have to look to Europe, because it is in Europe where the Diesel engine had its conception, and where it has been perfected to the highest stage of completion. The history of the Diesel engine in Europe has proven that all the parts which are subject to wear, at least in a well-designed engine, can be replaced at a cost of about 35 to 40 per cent. of the initial cost of the engine. These parts include pistons and cylinder liners, for instance, valves, bushings, and all those parts that are subjected to natural wear of the engine. It, of course, does not include any breakages like broken crank shafts. But such a thing doesn't occur in a good Diesel engine. European practice has brought out that these parts will stand up easily from eight to ten years.

Mr. Setz was in 1901 connected with Dr. Diesel, and was then testing a two-cylinder engine, which some of the engineers that were in Europe about two years ago undoubtedly saw. That engine is operating a match factory in Bavaria now, and at that time, had been in operation for twelve years. The pistons and one cylinder liner have been replaced in that engine; all the other parts are practically the same parts as the original engine contained, and that after twelve years' operation.

In one of the two papers that were presented Mr. Setz noticed that the depreciation is figured at ten per cent. In view of these experiences he thought ten per cent. was far too high to figure. It is doing the Diesel engine an injustice if ten per cent is figured, because in less than eight years the whole Diesel engine will have depreciated from its original purchase value to nothing. He would recommend a depreciation of about four per cent. in trying to arrive at the cost of the power produced in a Diesel engine, including the capital charges.

The other question is, of course, the fuel question. There are about as many different kinds of fuel oils as there are of Diesel engine operators, referring to their suitability. A thing which he thought ought to be done in this country, and probably by the American Society of Mechanical Engineers, is to make a systematic study of fuel oils. There is quite a precedent for work along that line in the more recent European literature. For instance, in Switzerland, a very comprehensive study was made by actually running a Diesel engine for two and three weeks at a time on various fuels. Unfortunately, the fuels that were tried were all, with one or two exceptions, European oils, from Galicia and Roumania and Baku. There were only two American samples of oil used; one was an Oklahoma oil and the other a California oil, which means that only asphalt base oils were used in the tests.

Asphalt base oils are what ought to be investigated. The ordinary manufacturers haven't the time, and most of them haven't the inclination to allow the chief engineer to spend any great amount of time in making such investigations, and he thought that if the fund which is now in existence in the Society for carrying on research work could be drawn upon to carry through such experiments in one of the laboratories of our leading schools under the supervision of several faculty members—impartial men—he thought very good results would be obtained.

Referring to a few examples of what his experience had been on asphalt base oils, Mr. Setz said there is no standard definition for asphalt. Asphalt is defined sometimes as the residue which remains after heating the oil for a certain number of hours at a certain temperature in the open air bath, as it is called. What remains after such a heating process is ordinarily called asphalt. But the residue contains many other things than asphalt, so that is not a conclusive test at all.

He had had one of the greatest surprises in his life when he started out the first Diesel engine in the Southwest. They told him the oil contained 50 per cent. asphalt, and he thought he might as well go home, because that engine would never run on that stuff. Yet to his great surprise, the engine ran and is running to-day with nothing else than that particular grade of oil. It is a California oil of 14.6 gravity, Baumé, and the engine can even be started and it it regularly started on that kind of oil—a thing which no engineer in Europe who has had European practice would believe possible unless he saw it.

Another method of determining asphalt is by a chemical analysis, and even in that there is no standardization, as Mr. Setz understood. He said he was not a chemist, and could not give conclusive definitions about it, but he understood that even among chemists, there is a difference of opinion as to just what asphalt is. He thought this question ought

to be cleared up, and a standard adopted by means of which the oil is designated in the future. It would, he said, be a great help to manufacturers, and a far greater help even to users.

Mr. Setz referred to a publication which came out about a year ago, covering a lot of very interesting and important research work by the United States Geological Survey, covering asphalt base oils, California oils especially. The usual method of designating an oil in regard to its suitability for operation in Diesel engines is to give the gravity, either Baume, or specific gravity. If one goes through that pamphlet and plots graphically all the values that are given for these various California oils over the specific gravity, it will be found that the heat values range from 18,000 to almost 20,000 B.t.u. per pound, and that the percentage of asphalt contents given there varies from about 40 to 42 per cent. It will also be found that what is called kerosene varies also within certain limits. All these things indicate that specific gravity is not the only criterion for determining the value of fuel oil. This is one of the points that ought to be settled, and he believed that no better arrangement could be made than to having the American Society of Mechanical Engineers take this matter up, as it is strictly a mechanical engineers' proposition.

Another matter in connection with oils which Mr. Setz said was referred to several times in one of the papers, is the percentage of water. The percentage of water is not in itself enough to designate the oil as to its suitability for Diesel engine use. For instance, he had been operating on a Mexican crude oil which contained over 2 per cent of water, and the engine ran for quite a while very nicely. All at once it began to run jerky, irregular, and finally, it shut itself down. After investigating he found out that this Mexican crude oil was so heavy that the water remained in it suspended in very small drops, and did not separate out but very little. These very small particles of water, had been pumped in gradually with the oil into the injection valve—not into the cylinder, but into the injection valve on the atomizer plates. That piece of apparatus which will be found described in one of these papers, serves the purpose of disintegrating the fuel before it is injected, and the atomizer plates have a temperature high enough to evaporate the water. This water vapor rose inside of that injection valve space to the upper end of the injection valve, and there gradually condensed and formed a drop big enough so that afterwards, when it was blown into the cylinder, it shut the engine down. The Diesel engine will run on almost anything, but not on water, so there is where the water content would have an effect.

Another oil which contained about 5 per cent of water did not cause any trouble at all, because the oil was of such a constituency that the water was easily separated and could be drawn off; no water came into the cylinder at all.

Another feature of California oil especially, Mr. Setz finds, is the contents of the salts. These salts in the oil dissolve, and when the oil is burned in the cylinder, they form a deposit that, being a form of silicate, is a very effective grinding medium, and will wear out cylinders. Some do not show the effect at all, and others show it in very pronounced manner. This is another thing that ought to be investigated in connection with oils. If the Society could make a systematic investigation, Mr. Setz thinks it would be of great benefit

to this new industry, which promises to become of far greater importance here than it has reached in Europe.

R. L. ROWLEY asked Mr. Setz what was the smallest size of four and six-cylinder engines, and also the weight now adopted for Diesel work in European practice?

H. R. SETZ said the question of weight is entirely dependent upon the speed of the engine. Up to a short time ago, in order to meet requirements of smaller submarine construction, speeds were increased and weights reduced beyond what is considered desirable limits to-day. Later practice is tending towards heavier weights and more rigidity in the engine, so as to insure longer life.

C. R. WEYMOUTH said there is no class of investigators, or no class of experimenters that deserve more credit than the men who have developed and are developing the Diesel engine. They have had to face almost insurmountable difficulties, and he thought the degree of success that they have accomplished is remarkable. They have not, however, conquered the field, and there is a great deal to be said that is not in favor of the Diesel engine, and it was that portion of the subject that he wished to cover briefly.

His own experience had not extended to the Diesel field. About fifteen years ago his company undertook to exploit the Westinghouse gas engine on this coast. They installed between half a dozen and a dozen Westinghouse engines averaging from 50 to 100-h. p. Within two or three years time, after these engines were installed, he thought, every one of them was out of commission. He remembered a letter written to an engineer in connection with one of these plants operating a pump, and this letter was by a person who wished to ascertain the reliability of that type of engine. The party answering the letter stated that it was the most satisfactory gas engine that he knew of; they had made some alterations since it was first installed—they had removed the piston rod and the piston and had put an electric motor on the other end of the shaft, and it was then working perfectly.

Following this period there was installed at Martin's station near this city probably the largest gas engine plant in the United States, other than in the steel industry. This plant had four 5000 h. p. gas engines built by the Snow people. These engines were to run on manufactured gas; they were not involved with any problems of moisture, or silt, or asphalt. It is a well-known fact that the engines were never accepted; after a few years trial, at great expense, the engines were rejected, and their failure cost the International Steam Pump Company the sum of about one million dollars.

Mr. Weymouth asked the Diesel gentlemen here why it is that if engines designed to run under less difficult conditions result in failure, that a much greater degree of success can be expected from the Diesel engine. He knew the Diesel engine had attained a great degree of success, but he didn't understand the reasons for it, and would like to hear from them on that subject. He thought all engineers would admit that the Diesel engine is the most efficient type of prime mover known, and it is probable that no other type of prime mover will ever closely approach it in efficiency. He

thought, however, that the majority of engineers would agree that that one advantage is about the only advantage of the Diesel engine, and that, starting from the saving in fuel resulting from its use, there must be subtracted a good many items of operating expense which result in a final operating cost which is not anywhere nearly as favorable as it might appear from the operating efficiency.

When we consider an engine operated with cast iron cylinders, with a temperature of the fire of from 2500 to 3000 deg. and with a piston floating in this flame, the difficulties of complete combustion under those conditions will be appreciated. As a result of the high temperatures and the other attendant troubles from the presence of moisture and silt, the operating troubles of the Diesel engine multiply, and in most of the plants that he had knowledge of, the operating cost is a material figure.

The Diesel engine was developed in Europe where, as a spur to its development, they had the highest fuel cost of any locality, and the saving based on this high fuel cost was such as to warrant a considerable margin in covering such losses as maintenance, high repair cost, operating costs and depreciation. In Europe also they were able to obtain at a comparatively low rate the highest skilled mechanics; they were able to do machine work with a degree of accuracy not formerly known in this country. All of which conditions were conducive to the best development of the Diesel engine. When the Diesel engine is transferred to the Pacific Coast, however, it will find probably the cheapest fuel cost of anywhere in the world. With crude oil at 60 cents a barrel, the fuel is one of the least items of the cost of a power plant, and whatever the percentage of this fuel saved, it means a small saving in dollars and cents.

Furthermore, we have in this country men who are not highly developed in the operation of delicate machinery, and it cannot be expected that the Diesel engine will arrive at its best until after quite a number of years. In our mining regions, where the Diesel engine would find its best development, men are found who are little better than tramps in a great many cases, as men who are skilled mechanics can secure profitable employment in the coast cities, and it is quite a problem to obtain operators who will stay in these unattractive desert locations.

Mr. Weymouth referred to Mr. Adams' paper on page 7: "The Diesel engine is in use to-day in almost all places where a steam engine or turbine might be used." He said that is a very broad statement and might easily be misleading, and the best way to answer a statement of that sort is to go immediately to an extreme. He mentioned that the Commonwealth Edison Company of Chicago is to-day contemplating the installation of a single turbine of 50,000 kw. capacity, and he compared that with an installation of Diesel engines. The largest Diesel engine built in America to-day, that he was aware of, was an engine of about 800 kw. capacity, and of about five cylinders per engine. It would require 60 engines of that size to develop this 50,000 kw. capacity. There should be, say, from five to ten engines reserved; if this reserve figure be called ten, there should be 350 cylinders in a Diesel engine plant to develop the capacity of one steam turbine.

If we go to the question of labor, it will be seen what an enormous number of men would be required. As to the

question of floor space, it would probably be found that there is not a single tract of land in the city of Chicago available for a plant of that capacity. That comparison may be unfair and probably is unfair to the Diesel engine, because he understood they are building larger sizes in Europe, although at the present time these are still in the experimental stage.

On page 14, Mr. Adams gives a comparison of the most efficient steam plant with the most efficient Diesel engine plant. He assumes an efficiency of 34 per cent for the Diesel engine, and an efficiency of 20 per cent for a steam turbine plant. Mr. Weymouth said he knew of his own knowledge that it is possible to operate a steam turbine plant under its most efficient conditions with oil fuel, without undue expense of first cost; that is, with 100 per cent load factor (which is the basis that Mr. Adams is talking on) obtaining 300 kw-hr. per barrel of oil. Taking the ratio of 34 to 20 and multiplying it by 300, that would be for the economy of the Diesel engine plant 518 kw-hr. per barrel of oil. He knew of the records of a number of Diesel engine plants, but he didn't know of any plant which is operating as efficiently as that. The best claims that he knew of are in the neighborhood of 0.7 lb. of oil per kw-hr. And if this be taken on a light oil, which will weigh about 300 lb. to the barrel, it would give somewhere from 400 to 450 kw-hr. per barrel of oil for the Diesel plant. Mr. Adams gives, in his paper, an economy of 447 kw-hr. per barrel of oil, which he thought was a fair comparison.

Mr. Weymouth pointed out that Mr. Adams gives a comparison on page 20 of the cost of the small turbine and the small Diesel engine plant, rating this at 600 kw. He said Mr. Adams had in mind, no doubt, a fair comparison which would be used, thinking of a plant which would be used by a small municipality. In making this comparison the Diesel engine appears at its very best, and the steam plant appears at its very worst. In a plant of 600 kw. maximum capacity, he didn't think that even the advocates of the steam turbine would contend that it is best adapted for this work. There have recently been developed some small steam engines on the uni-flow principle and an engine also of the four-valve type, which are giving remarkable economies; they can be operated on superheated steam and will show better performance in the small units than the steam turbine.

The steam turbine has, of course, an undisputed field in units of larger size, and most people agree that above a 1000 kw. the steam engine has little field. The economies given for the turbine plant may be representative of the steam turbine, but are not representative of the best that is obtainable with steam, and for a steam engine plant properly designed, the fuel consumption would be materially less than indicated.

With respect to the selection of units, Mr. Weymouth didn't think that an engineer would select a 200 kw. and a 400 kw. unit for any municipal plant. The day is past when we put in several sized units in a given station. We don't try to fit the load curve with unit sizes, and in any plant the units should be about the same sizes, for the purpose of duplication and for simplicity in repairs. Even with steam engines he would say that for a 600-kw. plant the unit size should not be less than 300 kw., and probably three units or 300 kw.

For the Diesel plant Mr. Adams selected in one case three

200 kw. units, and in another case one 200 kw., and another 400 kw., but there are no spare Diesel engines. All the Diesel people will agree that a spare Diesel engine is necessary. If this is provided for, it multiplies the first cost of a plant in proportion to the spare, and the fixed charge is increased in this ratio.

On the other hand, in providing the spare engine of the turbine unit, it is not necessary to provide the complement of spare boilers and stacks and boiler house, and the additional spare is provided at a less cost than in the case of a Diesel plant.

Mr. Weymouth said the labor costs are not high enough for the steam plant, and are considerably too low in the case of the Diesel plant. The maintenance cost is taken at eight-tenths of 1 per cent for the steam plant, which is too low, and one-half of 1 per cent for the Diesel engine plant, which is many times too low.

Regarding maintenance, he said that the California State Railroad Commission, in passing recently on the maximum power cost, had allowed 1¼ per cent as the maintenance of a steam plant, and he didn't think the Diesel plant could be figured at anywhere near that cost.

Referring to the fixed charges, 14 per cent has been estimated as both the total of fixed charges for the steam plant and the Diesel plant; in both cases this includes the item of 6 per cent depreciation for both types of unit. The whole question of the selection of a Diesel plant or a steam plant for a small unit station will depend upon the relative figures assigned for depreciation. There are none of us in this country that know anything about it, and any figure today is more or less an intelligent guess. He had talked to a number of people who have had European experience, and they told him that the depreciation of the Diesel plant is about the same as a good steam engine. He had asked one of their marine department for some figures on the life of steam engines, and had received a list of steamers operating on this Coast since 1880 or 1881, over thirty years. The depreciation on that basis would be something under 3 per cent. He knew of Diesel plants which had been entirely rebuilt in less than five years; that is, their vital parts.

Taking the figures that Mr. Adams has given for the total cost of operation on a 25 per cent load curve, on 95 cent oil, his power cost is 1.3 cents per kw.-hr.; on \$1.50 oil it is 1½ cents per kw.-hr. There are any number of steam plants all over the country which will show much lower generating cost than that, including all of the fixed charges. There are steam plants on this coast which are operating at easily one-half of those costs.

The Diesel engine has the same economy and almost the same cost per horse power in small units as large units, and the improvement for the larger sizes would not grow at a rapid rate; it would probably be some better than indicated. He would say that Mr. Adams has made a very unhappy selection in taking a 25 per cent load factor to figure out a Diesel engine. He doubted if the advocates of the Diesel engine would pick a situation of that sort, or even recommend their engine for that load. It is well-known that the Diesel engine is best fitted for loads near 100 per cent load factor, because there the saving in fuel is enough to offset some of the greater fixed charges and operating costs.

In connection with Diesel plants working in desert loca-

tions where there is a scarcity of feed water, where there is generally a large content of scale forming matter, Mr. Weymouth asked if the Diesel engine cylinders and jackets are designed to permit the easy removal of the scale which is certain to accumulate. A steam plant, working with surface condensers, he said, is a good salt factory, due to the evaporation of water, and there is a very rapid accumulation of scale in the tubes. He knew of one plant where it was necessary to shut down the condenser every 28 hours, and to drill out the tubes with a twist drill. That condition would prevail in the jackets of the engine. It can be overcome by designing the engine to remove the scale.

Mr. Weymouth remarked that Mr. Setz gave an interesting record of an engine which had been running something like twelve years, but that he didn't give any information as to the kind of oil used, whether it contained silt or other impurities which would give rise to cylinder wear and cylinder ring trouble.

In connection with the submarine practice of the United States, they have on that Coast the greatest amount of Diesel engine experience. The submarines were among the first Diesels on the Pacific Coast. They began with crude oil, but changed successively until they found it was necessary to run with a rather high gravity oil, something similar to Star oil, of about 30 gravity, before they could overcome their troubles.

In connection with the recent discussion as to why so many of our submarines are out of service, it has been pointed out by some of the authors of the Navy, writing articles for journals such as the Army and Navy Journal, that it has been found very difficult to keep these engines in reliable condition. The first report on the sinking of the submarine F-4 at Honolulu, mentions the difficulties of the Diesel problem in general, the unreliability of them, and the difficulty of keeping them in regular operation, but does not assign that as a reason for the sinking of the submarine.

Mr. Weymouth would say in closing that he thought these papers are both interesting contributions to the Diesel engine situation, but he regretted, and he thought all engineers would regret, that it is either not possible to give more reliable information, or it is not the disposition to give more complete information regarding the actual cost of operation of going plants.

A very complete report on this subject was made by the National Electric Light Association in 1912, consisting of reports on 34 stations. That information, however, is not as complete as it should be, and it is claimed that the engines now being designed are better built than the engines that were then in operation. But if an independent engineer today, is to pass on the problem of the relative merits of the Diesel plant, or a steam turbine plant, or a steam engine plant, he can find a great mass of information as to the operating costs and economies of the steam plants, but he will hardly be able to go beyond the stage of guaranties by the Diesel people as to their operating economy.

What we need are records of the life of Diesel engines so that we can estimate intelligently their depreciation and operating costs in the shape of labor, and the maintenance cost, and when that is at hand we will be able to decide what the future will be in California.

Mr. Weymouth said in closing that about two years ago he had the pleasure of showing Dr. Risert, a prominent Ger-

man engineer connected with the Augsburg factory, over some power plants on the Pacific Coast. As he understood, Dr. Risert was one of the foremost Diesel engine designers in Germany, and he made the statement that while he was very favorable to the Diesel engine from the standpoint of its operation, the fuel cost on this coast was so low that he would not advise his people to attempt to cultivate the field here.

THE CHAIRMAN: Mr. Dickie, then said they had had both sides presented very fully in regard to the Diesel engine. He was sorry that they did not go a little more into the marine Diesel engine, because he was somewhat interested in that. About five years ago a prominent shipowner in San Francisco wanted to try the Diesel engine; he had a boat building for his lumber business, and wanted an engine of 1200 h. p. The owner told him that he could spend \$100,000 on that engine if he wanted to, so he wrote to a firm of engine builders whom he knew very well and could depend on. They asked for samples of the oil to be used, and he sent them some twenty samples of oil from the California wells, just as it came from the wells. They would not undertake to build any Diesel engine that would run and be depended upon with that kind of fuel. On that account the application of the Diesel engine to the Coast shipping service stopped, and there has been no other attempt made that he knew of to bring the Diesel engine to service on that Coast. However, he said they may get to a Diesel engine that can be depended upon—and, really, he said, up to certain sizes, they are dependable to a certain extent, although the operating expenses, as shown by Mr. Weymouth, are pretty high, and the engine room force have to be all skilled men.

Mr. Dickie said they had one ship in there not long ago with 2200 h. p., which is a very small installation for a ship, and it had ten certificated engineers. That wouldn't go here, he said. A Swedish certificated engineer doesn't get very much wages; he is paid about the same as we have to pay a fireman here, and that makes quite a difference. All these things have to be taken into account when we come to the matter of deciding whether the Diesel engine, or some other form of engine is the best thing to use for any specific purpose that we have in view.

A. H. GOLDINGHAM said in response he thought most of the criticisms had been on the Diesel engine rather than on the hot surface type engine. He called attention to the fact that his paper was on the heavy oil engine, both the hot surface and the Diesel. But there were two things that he would refer to.

First of all was the cleaning out of the water spaces. In the later designs of engines this has had particular attention. First, there is a separate liner for removal in the cylinder, so that the scale can be removed, and also hand holes are provided, so that they can be well taken care of, both in the cylinder head and in the cylinder itself.

Second, with regard to the cost of operation, there is no question but that the oil engine, to have its best advantage, must be where fuel is expensive and where the load factor is high. The oil engine, as he had pointed out in his paper, to show to the best advantage, must work at or near full load all the time. Of course, its great advantage is the economy of fuel. Where you get very cheap fuel its advantage fades away slightly.

PAPER BY G. H. MARX AND L. E. CUTTER

DISCUSSION

L. D. BURLINGAME remarked the fact that Prof. Marx has carried out his series of investigations to cover one of the features which go to make up a successful gear whets our appetites for further investigation along the lines of efficiency in gearing, and to cover other important factors which go to make up successful running gearing. Some of the other factors are the matter of wear and the matter of quiet running, and we can only get at the most satisfactory or successful system of gearing by taking all of these matters into consideration, rather than taking one. While an investigation of this character is of value as giving data on which we can base further investigations, before we can decide what is the best system of gearing, we must have these other matters also taken into consideration.

For example, the Committee on Standard System of Involute Gearing, which investigated various systems, found from their tests that the $14\frac{1}{2}$ deg. angle gear gave a decided greater percentage efficiency, and a quieter running gear. In arriving at a compromise which will give us a system of gearing for universal application, these things must all be taken into consideration, and as he understood, the matter could be carried further if funds were available. It seemed to him that a very desirable use of funds which might be available for research work could be made to carry out further experiments along these lines.

The question of strength of gearing, Mr. Burlingame stated, is affected very possibly by this consideration: that with the small pressure angle ($14\frac{1}{2}$ degrees for the Brown & Sharpe system) the pinions being the weaker element, that is, where a small pinion runs into a large gear, the engineering solution is to make the gear of steel, or if further strength is required, to temper the pinion and thus get the benefit of strength without sacrificing the question of wear or of quiet running.

In the paper of Prof. Marx, it is interesting to note on page 7, where the figure is given for the actual breaking load of the Brown and Sharpe gear, that the curve of actual break is materially higher than the theoretical curve on which the figures are based. This is interesting as showing that the figures as given in this pamphlet are on the conservative side and are such as can be used with safety, that is, with a larger margin of safety than perhaps the actual facts would warrant.

It is also interesting to note the suggestion as to contact with more than one tooth during the action of the gearing, with a question mark against the three teeth being in action during certain parts of the action of the gearing. This is largely a matter of accuracy of cutting and of the system on which the teeth are based. He doubted if in many cases three teeth are actually in operation, from the fact that the point of the tooth of the ordinary Brown and Sharpe gear is eased off for quiet running in a machine; that would probably prevent actual contact unless under extremely heavy pressure.

Mr. Burlingame felt that Prof. Marx's contribution is one

of direct value to the engineering profession, and sincerely hope that the work can be carried further.

KATE GLEASON said that one of the very interesting things to her that Professor Marx had found in studying the Lewis formula as compared to the work he is doing, is that the strength did not fall off on high speeds, as he found, as rapidly as Mr. Lewis found it. The trouble they found is just as Prof. Marx found, that the strength does not fall off at the high speeds, but the load is apt to be so much harder—the starting and stopping at the high speed—that a great deal more has to be allowed in practice than in tests.

For instance, in rolling mill machinery, running at a high speed as it often does, if they are trying to run mills with motors almost double the strength has to be given than would in even the Lewis formula, whereas, in the Lewis formula on machine tool gears it is found more than ample. It seemed to her that as the loads come on so quickly, it acts almost like a hammer on the gears and crystallizes the material, and though the material may be plenty strong enough for the first month or two, it will disintegrate if not provided for, perhaps by putting in nickel steel, or something of that kind.

Miss Gleason stated that they found in the same way in testing worm gears, that they will not show up on a test at all as they do in practice. We have had papers here showing efficiencies up to 90 per cent on worm gear drives, but when we go out in practice, where the load comes down and makes so much friction, we cannot get 20 per cent out of it sometimes.

G. H. MARX replied that it had been peculiarly interesting to him to have Miss Gleason discuss the paper, because it was about twenty-five years ago, when he was working for the Gleason works in Rochester, that his first interest in gearing began, in connection with the preparation of a trade catalogue and pamphlet—a small treatise on gearing, which he had to get out. That interest had never failed, and although these experiments have been very tardy in coming off, he was very glad to have them done now.

What has been said by both speakers he heartily agreed with. In the first place, these experiments are limited merely to the question of strength, which is a very small part of the whole problem, and they are limited to cast iron gears. But he said, the only way to get an investigation done is to take a small portion of the field and cover it as thoroughly as can be, and then take the neighboring area and perhaps go into that. It takes a great deal of time, as any one who has carried out any investigation knows, to clean up even a small portion of a question like this.

As to the question of the falling off according to speed, of course, it was as Miss Gleason said, and she must remember that these tests were made under running conditions. He said their plea is that where there is shock, where there are reversals of stress, or where the stress is suddenly applied, that factor should be taken care of by a proper factor of safety and not in a velocity coefficient. So they have separated those and have a factor of safety in their formula, in which the question of the matter of application of load, or the question of reversal of stresses is provided for.

JOINT MEETING AT PROVIDENCE

An unusual joint meeting of local sections of the Society took place recently in the joint gathering of the Boston local section with the affiliated society, the Providence Association of Mechanical Engineers. The occasion was made notable by the attendance of several prominent engineers from distant points, who delivered addresses on engineering topics, and the opportunity for social intercourse was taken advantage of by a dinner gathering at which 520 were seated, preceded by a number of excursions to industrial plants in the afternoon. The meeting was said to be one of the most successful ever conducted by an engineering organization.

A JOINT meeting of the local section of the Society of Boston and of the affiliated society, the Providence Association of Mechanical Engineers, was held at Providence, R. I., on November 18, 1915. Members and friends to the number of 290 arrived in Providence by special train from Boston early in the afternoon, and proceeded at once to visit several of the manufacturing plants of the city.

At five o'clock they arrived at Brown University to inspect the engineering laboratories, and at 6.15 P.M., 520 engineers and friends sat down to dinner at the Narragansett Hotel, the largest gathering of engineers that ever dined together in Providence. Many could not attend on account of lack of room.

After dinner the visiting engineers were welcomed by Mr. Arthur H. Annan, President of the Providence Association of Mechanical Engineers, who said:

We are in the midst of a great industrial centre. Its prosperity depends upon the success of those industries, which in turn depend upon the successful efforts of their engineers. Their work is done singly or in small groups. We are constantly, and increasingly, witnessing the great achievements of organizations by concerted action, and who more than the engineers should appreciate and profit by such proceeding? I believe that we may profit and extend our influence and coöperation to every phase of our industrial, commercial, educational, social or any other function of a civilized community which is influenced by the work of engineers.

Dr. W. H. P. Faunce, President of Brown University, was then introduced by the toastmaster, William Howard Paine. Dr. Faunce said that he represented the "poor college professor," while the engineers represented, not the "malefactors," but the factors of great wealth. Continuing, he told of:

A certain country preacher, who met a famous baseball pitcher, and said to him: "What is the cause of the difference in our salaries? I get \$500 a year and you get \$5000. Moreover, I work twelve months in the year and you work only three and yet my salary is \$500 and a miserable little parsonage thrown in, and you get \$5000. What is the reason for that?" And the famous pitcher said: "I suppose the difference is all in the delivery!" While there is a great deal of difference in our delivery, yet there may not be after all so much difference in the things we are aiming at. On an evening like this I am conscious of the unities rather than the divergencies.

It has often been assumed in America that the men of thought were utterly distinct from the men of action; that the men of thought are to be found inside of the college fence, and that the men of action are outside in the world doing things without any deep intelligence. But the engineering profession stands for the union of thought and action. It stands for intelligence and labor, for thoughtfulness put into industrial and commercial enterprise, and says to all the world: "Your labor is thrown away, unless you think as

you work." On the other hand, it is equally clear that thinking will come to little unless somehow it is harnessed into the great creative activity of the age."

Following Dr. Faunce, addresses were given by Professor Charles E. Munroe, Washington, D. C., on Explosives and the Engineer; by Morris L. Cooke, Philadelphia, Pa., Mem. Am. Soc. M. E., on Experiences of an Engineer in Public Office, and by M. C. Rorty, New York, on The Development of a National Telephone System.

After Mr. Rorty's address moving pictures were shown of the construction of and scenes along the transcontinental telephone line. At 9.30 P.M., through the courtesy of the American Telephone & Telegraph Co., telephone connections were made with the Exposition grounds at San Francisco, Cal., every person present having a receiver connected to the transmission line so as to hear the long-distance conversation.

EXPLOSIVES AS AN AID TO ENGINEERING

BY CHARLES E. MUNROE,¹ WASHINGTON, D. C.,

Non-Member

Engineering is one of the oldest of the professions. But as we contemplate the temples, the tombs, the pyramids, the obelisks, the fortifications, the highways, the aqueducts, the viaducts, the mines and tunnels and the other monuments to man's achievements which have come down to us from most ancient civilizations in many parts of the world, in view of the tools, appliances and materials now at the command of and in use by the engineer, one is led to inquire into the means by which such work was then accomplished.

Although gunpowder is recorded as having been used as a propellant at the siege of Baza by the king of Granada in 1323, its first appearance in military engineering operations, as recorded, was at the siege of Merat in 1397, where it was used for springing mines. In 1585 it had come to be used in marine devices, for, in that year a bridge in Antwerp was destroyed by a floating torpedo. The first reputed application of this agent to peaceful pursuits is attributed to Martin Weigold (Weigel) at Freiberg, Saxony, in 1613. Guttman doubts this because as late as 1617 Lohmeyss wrote "on the soft veins they work with pick-axes, but in the solid ones with gad and mallet." Guttman recognizes that the art of blasting was naturally an evolu-

tion and holds that the first practical application of which there is authentic record was made by Caspar Weindl on February 8, 1627, in the Oberbiberstollen of Schemnitz in Hungary.

For over two centuries gunpowder remained the only available blasting agent, but in 1845 Schoenbein discovered gun cotton, in 1846 Sobrero discovered nitroglycerine, in 1866 Nobel invented dynamite and a new era in explosives for engineering uses began. Guttman dates the application of these new sources of energy to blasting as 1854, but without citing person, substance, or place. In the early days of blasting the charge in the bore hole was ignited through the stemming by spills or squibs, consisting of straws, quills or rush tubes filled with fine powder. In 1831 William Bickford invented the running fuse in use to-day wherein a thin, continuous core of powder, along which the fire might slowly travel at uniform and determined rate, was enclosed in a jute tube. In 1867 Nobel introduced detonators.

To-day the preferred method of firing blasts is by electricity; therefore Americans should be interested to know that history states that Franklin, in his Letters on Electricity (June 29, 1751), was the first to suggest the employment of frictional (or static) electricity for the ignition of gunpowder, and that in 1831, Moses Shaw of New York, made the first application of this method to the firing of mines. Meeting with practical difficulties in putting his invention into industrial operation Shaw, on June 1, 1831, appealed to Dr. Robert Hare of the University of Pennsylvania for advice and assistance, and the latter applied his famous delagator or voltaic battery and a wire bridge to this use with such complete success that, though the generators for the electric current have been altered in form and character, and the detonators in details, the method devised by Dr. Hare is the method which is to-day in universal use throughout the world for the firing of blasts, mines, or torpedoes by electricity. This method was demonstrated for use in warfare when in 1843 Samuel Colt blew up a brig under full sail in the Potomac from Alexandria, which was 5 miles distant from the brig, though in 1839 Sir Charles Pasley had removed the wreck of the Royal George at Spithead by the use of low tension fuses.

The blowing up of Flood Rock in Hell Gate, in New York City, was successfully accomplished October 10, 1885. Flood Rock had a superficial area of nine acres, about 250 sq. ft. of which was above water. The rock consisted of horn-blende gneiss, with intersecting cross-veins. A sea-wall 7 ft. high was built around the island, and two shafts were sunk, one 67 and the other 40 ft. deep. The main shaft was used for removing the excavated rock in blasting out the headings. The smaller shaft was used for the tubes conveying the compressed air which drove the drills. The first series of headings branched out from the main shaft at a depth of 40 ft., and from the bottom of the shaft another series diverged directly under those above. The headings branched at right angles every 20 ft. and were 60 in number in each tier. The double system of headings was employed to gain a sufficient depth after the explosion without the necessity of dredging out to the extent that was found necessary at Hallett's Point. The total length of tunneling was about four miles, consisting of 24 galleries running north and south and 46 running

east and west. The longest of these was 1200 ft. in length, 6 ft. wide and 10 ft. high. There was a thickness of from 10 to 25 ft. between the roof of the top tier of galleries and the water. There were 467 pillars, 15 ft. square, left to support the roof. The whole rock was honeycombed with tunnels, about 80,000 cu. ft. of rock having been removed.

There were drilled in the pillars and roof 13,286 chambers for holding the cartridges, each chamber being 3 in. in diameter and about 9 ft. deep. These chambers were filled with rackarock cartridges, of which there were about 47,000 used, each being 2½ in. in diameter and 2 ft. in length, and containing about 6 lb. of the explosive. In addition to the rackarock cartridges, several hundred ordinary dynamite cartridges were used, to which the wires leading to the firing batteries were attached. The shock resulting from the explosion of these dynamite cartridges caused the explosion of the rackarock. Upwards of 285,000 lb. of explosives were used in the charge.

The wiring in the mine was divided into 36 circuits, the batteries attached to these circuits being stowed in a tool-house on the rock. The wire of the primary circuit which actuated the electro-magnet that closed the secondary circuits was led across to the Astoria shore on the morning of the explosion. The firing-key was about 1200 ft. from the mine.

Two siphons, one 12 in. in diameter and the other 3 in., were set at work at 10 A.M., October 9, flooding the mine, and they completed their work early the following day. The first effect of the explosion was to produce a rumbling noise, and then to project a mass of water over an area of about 1200 sq. ft. to a height of about 150 ft. Masses of rock rose in the midst of this water to a height of from 40 to 50 ft. The explosion lasted about 30 seconds. As the water fell a dense cloud of yellowish smoke arose and floated over the Astoria shore.

After the explosion the rock appeared undisturbed, though on close examination it was found to be somewhat fissured. However, it slowly settled, and by October 13th the entire rock was below water. It was not intended that the rock should be broken very fine, since with the appliances at hand pieces of from ten to fifteen tons in weight could be most economically handled. The operation covered nine years, and cost upwards of \$1,000,000. (Proc. Nav. Inst. 9, 755; 11, 281.)

More than 30 years ago the author began a study of the conditions of efficiency in the use of explosives and in a paper published in Van Nostrand's Engineering Magazine for January 1885, which dealt with attacks on armor, demonstrated that the maximum degree of confinement for the explosive and penetration by the projectile were the essential conditions. In 1898, apropos of the use of the dynamite gun at Santiago, I returned to the problem and published my results in Cassier's Magazine of that year, of which I gave a resumé in an address to the citizens of Cleveland on behalf of the American Association for Advancement of Science and which appears in the Popular Science Monthly for February 1900 as follows:

There is a widespread misapprehension in regard to the devastating effect of these high explosives, for when unconfined the effect even of large charges of them upon structures is comparatively slight. At the Naval Ordnance Proving ground, so long ago as 1884, repeated charges of dynamite, varying from five to 100 lb. in weight, were detonated on the

face of a vertical target consisting of eleven 1-in. wrought-iron plates bolted to a 20 in. oak backing, until 440 lb. of dynamite had been so detonated in contact with it, and yet the target remained practically uninjured; while at Braamfontein the accidental explosion of 55 tons of blasting gelatin, which was stored in railway vans, excavated but 30,000 tons of soft earth. This last may seem a terrible effect, but the amount of explosive involved was enormous and the material one of the most energetic that we possess, while if we compare it with the action of explosives when confined, its effect becomes quite moderate.

At Fort Lee, on the Hudson, but two tons of dynamite placed in a chamber in the rock and tamped brought down 100,000 tons of the rock; at Lamberis, Wales, 2½ tons of gelatin dynamite similarly placed threw out 180,000 tons of rock; and at the Talcen Mawr, in Wales, seven tons of gunpowder, placed in two chambers in the rock, dislodged from 125,000 to 200,000 tons of rock. We might cite many such examples, but on comparing these we find that the gunpowder confined in the interior at the Talcen Mawr was over forty-two times as efficient as the explosive gelatin on the surface at Braamfontein, while the dynamite at Fort Lee was over ninety times as destructive.

These views have received but little consideration from officials in this country and our Government has gone on spending money in the testing and use of devices which were certain to prove ineffective. However, I confidently point to Liege, to Namur, to Antwerp and to the effects of a multitude of perforating high explosive shells used in the present war in confirmation of the principles I developed. One has but to scrutinize the pictures in the *Scientific American* for October 30, 1915, showing the effect of shell fire on the Emden to be convinced of the accuracy of these conclusions.

Shortly prior to 1898, and while he was Chief of Bureau of Ordnance, U. S. N., I was asked by Captain Sampson to assist in the tests of armor piercing projectiles then being conducted at Indian Head by Comdr. Conden by securing a high explosive charge for them. This was done and after proving an excellent degree of fragmentation in the fragmentation pit a shell containing 8.25 lb. of the explosive was fired through 14.5 in. of the Harveyized armor of the U.S.S. Kentucky and exploded on the inner side. So far as records go this had then never been approached.

When Admiral Sampson took command of the fleet he wrote me asking my assistance in securing high explosive charges for the armor piercing projectiles of his fleet. I delivered his message and used my best endeavor, but the material called for was not sent and it remained for the Japanese to be the first to demonstrate in practice the soundness of these principles.

This study was continued and extended to bore-holes in blasting operations by my pupils, Clarence Hall and W. O. Snelling, and their results and conclusions were published in 1912 as Technical Paper No. 17 of the Bureau of Mines under the title "The effect of stemming on the efficiency of explosives." It was naturally of interest to learn that a manager of a considerable mine reported a saving of \$50,000 in his explosives' account in a single year by following the methods for using stemming taught by this research.

More recently Edgar A. Collins has stated in *Min. Sci. Press*, Vol. 110, p. 790, 1915, that he has found in practice where 30 per cent ammonia gelatin was being used in a given mine a saving of 25 per cent in quantity of the explosive was effected by increasing the depth of the tamped stemming above the charge and that as a consequence the amount of

explosives issued to the miners had been cut to from 10 to 20 per cent of that formerly issued.

It should always be remembered that the gases produced by explosives in exploding have other properties than that of yielding larger volumes than the solids from which they are produced, for some of them are poisonous. The kind of gases produced differs with the kind of explosives used and the way in which it is used. Nitric esters and nitrosubstitution compounds and the mixtures, such as dynamite, made from them, may yield poisonous nitrogen oxides and cyanogen, and poisonous and inflammable hydrogen sulphide and carbon monoxide. But if the explosive be properly compounded, well confined, and fully detonated, these harmful gases will not be produced, for the gaseous products will then be largely composed of water and carbon dioxide; and though carbon dioxide may cause unconsciousness and even death, it does so only when it forms a large proportion of the atmosphere. Blasting powder and gunpowder-like mixtures give off poisonous and inflammable hydrogen sulphide and carbon monoxide under all conditions of explosion.

The production of inflammable gaseous products underground, especially in coal mines and bitumen mines, is most hazardous. The production of poisonous gases, either below ground or on the surface, is a source of danger, and if such gases are formed they should be removed by ventilation before anyone is allowed to approach the working place. Neglect of this precaution led to the death of 7 persons and the rendering of 40 others unconscious from gas poisoning following the firing of 21,000 lb. of blasting gunpowder at the Cranae quarry, Loch Fyne, Scotland, on September 25, 1886. The quarry was situated in a basin in a hill with sides rising 25 to 250 ft. and was approached by a narrow gorge. The blast was fired in the presence of an audience of over 1000 persons and at least half an hour after the blast 120 got into the quarry to observe the effect, and within five to six minutes after entrance they began to fall, overcome by the poisonous powder gases entangled in the crevices of the rock that had been thrown down.

In a large engineering project in the West nine men lost their lives as a result of the poisonous gases produced on the detonation of 40 per cent strength gelatin dynamite in a long tunnel. After igniting the blast the men retired about 500 ft. to wait for the smoke to clear, and while they were waiting the smoke drifted slowly over them, and then, owing to some change in the air current, drifted slowly back again. The men felt the usual symptoms of carbon monoxide poisoning—slight choking, nausea, profuse perspiration, and headache—but they all revived upon reaching the open air about an hour and a half after the blast had been fired. Within a short time, however, the men began to cough and spit bloody mucus and show other symptoms of nitrogen peroxide poisoning. In less than three days 9 out of the 13 men who had been in the tunnel and exposed to the fumes had died; the other four, as well as those who went in with the motor to bring out the men, were ill for days and even months after the catastrophe.

It was soon after the accident mentioned above that special studies of the noxious gases evolved on the detonation or combustion of different explosives were undertaken by the Bureau of Mines to determine whether improvements could be made in the composition of explosives with a view to increasing safety in mining.

EXPERIENCES OF AN ENGINEER IN PUBLIC OFFICE

BY MORRIS L. COOKE, PHILADELPHIA

Member of the Society

Mr. Cooke prefaced his remarks by saying that he must admit experiencing somewhat of a thrill as a result of this large and enthusiastic meeting of engineers—more than could crowd into the hall. This event and the recent accomplishment of the engineers of his home city in their remarkable campaign for increasing the membership of the Philadelphia Engineers Club, by which it was raised from 560 to 2300, indicated to him a growing strength on the part of the engineering profession, and of a corresponding opportunity open to the profession.

He said that municipal administration, in which he had had a part, had been conducted on the assumption that there were almost no fundamental differences between public and private businesses. He believed that he and his associates had the right to claim that this was distinctly a novel idea in municipal administration, and that as the years went on it would be looked upon more and more as an important step forward. He said further:

The public official cannot do at all times all that he would like to do, which is as true also in private establishments. We sometimes assume that those in nominal control in business really control. But whether we speak of the men or the management, such control is only relative—never absolute. If much that we dreamed during the past four years was frustrated by those opposed to us, we must admit that it would be just as true in industry or anywhere else.

As an offset it can be claimed that anything good which is accomplished carries further because of the publicity which frequently comes to public business. The difficulty usually is that public officials are not always able to get publicity, nor to make the people understand their purposes and work. A man in private business frequently answers that he does not have to give his reasons—even resents being asked for them; but a public official should beg for widespread public discussion of public problems, for only in this way can he get the necessary public support for those things which deserve support. Too frequently the public has either half information or misinformation.

This assumption about the similarity of public and private business has stood us in good stead at every turn. Thus we have assumed that our Civil Service laws were only a codification of the best practices of private business and that considerations which would make John Wanamaker, Baldwin Locomotive Works, or any other good employer, either employ, discharge or discipline, should hold with us. Acting on this theory we have not once failed to get the man we wanted through Civil Service and the courts have not reinstated a single man, although it has been necessary to discharge hundreds.

In the broad group of municipal engineering activities none are of more importance than those classed broadly under the head of public utilities, including therein steam and electric railroads, gas, water and electric plants, and telegraph and telephone companies. When we came into office the municipality exerted almost no control over these prop-

erties, most of them both privately owned and privately operated.

The city had almost no reliable information about these utility companies and therefore was in no position to enforce the most modest demands either for improvements in service or readjustments in service. No one will ever know the difficulty we have experienced in ascertaining enough of the facts to put us in a fair negotiating position. Practically every American city is in the same situation. And yet every city should at all times be in possession of all the facts about every utility which serves it. We will look back some day upon this period of utility hide-and-seek as one does on the dark ages.

We look upon our activity in this field as our greatest accomplishment. We have not only wrought many local improvements in the utility situation in Philadelphia, but our influence has been felt all over the country. Largely as the outcome of our local difficulties, has come the National Utilities Bureau with a distinguished directorate, which with headquarters in Philadelphia is acting as a counselor and guide in utility matters to cities all over this continent. As a standardizing and economizing agency the influence of this bureau is already making itself felt. It provides the only forum in this country for the expert and untrammelled discussion of utility problems.

However great we may feel to be the opportunity of the engineer in this municipal field, the public will come only half way. As a profession we must go forward to meet our opportunity. No narrow view as to the scope of engineering can be tolerated, and we should bring to our aid the most exalted conception of service which we can command. Ever since I have been a member of The American Society of Mechanical Engineers, I have made the effort to arouse the interest of my fellow members in our responsibilities to the public as contrasted to those we owe to our profession. After four years of direct association with the engineering problems of the third largest city in this country, the necessity for your cooperation is all the more apparent. There is no national engineering society taking a special interest in municipal engineering. I wish ours could do so.

William Ostwald—one of the greatest leaders of present-day Germany—has called our attention to a fundamental difference between the science of the future and science as we know it to-day, or more particularly as we have known it in the past.

The change from a pseudo-science to a real science only comes when we begin to use the knowledge we have as to the present and the past to build a future which we then proceed to make come true. The astronomer bases his predictions as to the future on the race-long accumulation of data. The hour at which to-morrow's sun will set may have been figured out centuries ago and perhaps with an inspiring degree of accuracy, and yet such figurings have not the slightest influence on the event. In the same way species have come and gone and their life histories have been in no wise influenced by man.

In California, however, a Burbank pictures a flower with heretofore unheard of qualities—a new color, a new shape, or perhaps a new perfume. Then by combining and recombining known varieties under laws, some of them known and some of them not even recognized, and—presto! the sought-for flower. Again a Flexner in New York or an Erlich in

Frankfort draw the specifications for a bacillus that shall bear down some enemy of the race, and forthwith it is produced.

It does not require a great imagination to picture this force broadly at work in the field which has to do with the inter-relations of men. In greater and greater degree in the science of human institutions we will have the power, if we can get that point of view, to write the formulas for the future according as we see what will be for the benefits of our kind.

Engineering has had much of service in it. I am told by municipal researchers that, taken the country over, no other class of officials has a better record for probity or the painstaking execution of public trusts than have our municipal engineers. No one of us will underestimate the meaning of such a statement. Inspiring though a good record may be, all its value is lost if we do not use it as a stepping stone to something greater, to deeper service, to a more profound understanding of all that life of which we may be a part.

Engineering must more and more be looked upon as the great coördinating branch of human endeavor. To bring order out of chaos can be rightfully claimed as our job. More and more our client must be all the people.

THE DEVELOPMENT OF THE NATIONAL TELEPHONE SYSTEM

BY M. C. RORTY,¹ NEW YORK

Non-Member

Man has been called the "tool using animal," and his progress has been so closely identified in the past with his skill in the manufacture and use of tools that we hear frequently of the stone age, the age of bronze, and the iron age, as representing broad divisions in human evolution. But it is not proper to speak in terms of tools of the hand alone. We might, perhaps, more accurately speak in terms of the development of the tools of the mind, and might divide the years of man into the dumb ages, the age of speech, the age of picture writing and hieroglyphics, the age of the alphabet, the age of printing, and, finally, the ages of the telegraph and the telephone.

It was no accident when Alexander Graham Bell, more than 39 years ago, in the City of Boston, spoke into such an instrument to his assistant, Thomas A. Watson, over a line less than 100 ft. long, the first words ever transmitted by electrical telephone. Bell had been an instructor of the deaf and dumb, and, perhaps more than any man of his day, was practically familiar with speech and the mechanism of speech. He had that vision, inspiration, and enthusiasm which, in the inventor, is without price. His years of study and experimentation gave wings to that first telephone message.

It was no accident, also, that in the development from crude beginnings, which reached its logical climax on Monday afternoon, January 25, 1915, this same Alexander Graham Bell, in our offices in New York, talked with this same Thomas A. Watson in San Francisco, over a circuit stretching 3400 miles across the continent, and serving to unite into one great sys-

tem 9,000,000 telephones connected by 21,000,000 miles of wire.

And, finally, it was no accident that, in the last few days, this apparently finished work has been added to by trans-oceanic speech by wireless—with a whisper swelling, if need be, to hundreds of horse power, and spreading simultaneously in vast etheric waves, from Washington to the Eiffel Tower in Paris, on one side, and, on the other, to the distant Island of Hawaii.

Hundreds of inventors and engineers, in the 40 years since Bell and Watson held their first telephonic conversation, have labored ceaselessly for these great results, and levies have been made upon every branch of science and mechanics.

The problem has been a difficult one, not from its magnitude, but rather from the very subtlety and delicacy of the forces with which the engineers had to deal. It was not much more difficult to string wires from Denver to San Francisco than from New York to Denver, but the physical construction of the line was the least of the troubles. The real problem was to make that line talk, and to send 3000 miles with the breath as its motive power. The voyage of the voice across the continent is practically instantaneous. If its speed could be accurately measured, a fifteenth of a second would be nearly exact.

But the breaking of speed records is not the only thing which the telephone must accomplish. It must also guarantee safe delivery of the millions of tiny passengers which it carries every few seconds in the form of electrical waves created at the rate of about 2100 per second.

A breath against a metal disk changes air waves into electric vibrations, and these vibrations, millions upon millions of which are required for a single conversation, must be carried across the continent and produce the identical sound waves in San Francisco that were made in New York or in Providence. This task is so delicate and so fine as to be gigantic.

The transcontinental telephone line is much more than a mere scientific achievement. No one who stands in a modern telephone exchange in a great city and watches the tides of human activity ebb and flow—rising now swiftly with some great public crisis, falling with equal swiftness when the crisis passes—can fail to realize that this line is but the last link in the building up of a vast, sensitive, and truly universal service.

Such a service was anticipated in a remarkable way by the inventor-prophet Bell when he wrote, just two years after his first telephonic conversation had taken place:

It is conceivable that cables of telephone wires could be laid underground, or suspended overhead, communicating by branch wires with private dwellings, country houses, shops, manufactories, etc., etc., uniting them through the main cable with a central office, where the wires could be connected as desired, establishing direct communication between any two places in the city. Such a plan as this, though impracticable at the present moment, will, I firmly believe, be the outcome of the introduction of the telephone to the public. Not only so, but I believe, in the future, wires will unite the head offices of telephone companies in different cities and a man in one part of the country may communicate by word of mouth with another in a distant place.

But even so farseeing a man as Bell must seek aid when it comes to establishing a public utility of continental scope. And we shall fail in our duty to-night, if, in paying tribute

¹ Engineer, American Telephone and Telegraph Co.

Presented at joint meeting of the Providence Association of Mechanical Engineers and the Boston local section of The American Society of Mechanical Engineers, held at Providence, R. I., November 18, 1915.

to the inventor, we fail to pay tribute, also, to the organizer, the constructor, and the engineer.

For many years this line from ocean to ocean has been the dream of Mr. Theodore N. Vail, president of the American Telephone and Telegraph Company, the goal toward which he has pushed and toward which he has steadily led his associates. This has not been an idle fancy of a dreamer, but the prophetic vision of a practical, forceful, capable man of unlimited business knowledge, who can see everything in telephony, except impossibilities. He not only cannot see impossibilities, but he will not admit that they exist.

At Mr. Vail's side through most of these years has been a slightly built, active, keen-eyed man, John J. Carty, chief engineer of the American Telephone and Telegraph Company, and the organizer and directing head of what is, perhaps, the most remarkable group of technical workers that has ever been assembled for the accomplishment of a specified purpose. Mathematicians, physicists, chemists, experts in design and manufacture, and experts in field construction—each man has been selected with the utmost care, and practically every university and scientific school in the country can count its graduates within the group. Team work, imagination, and thoroughness have been the secrets, if secrets there be, of their success. To award individual credit among so many who are deserving would be a hopeless task. The greatest element in the whole sustained program has been leadership.

As a mere piece of construction, the building of a telephone line across the continent is impressive. For instance, the line crosses 13 states; it is carried on 130,000 poles. Four hard-drawn copper wires, 165 1000 of an inch in diameter, run side by side over the entire distance, establishing two physical and one phantom circuit. One mile of single wire weighs 435 lb., the weight of the wires in the entire line being 5,920,000 lb., or 2,960 tons of copper. This amount of copper is required for the transmission lines alone. In addition, each one of the physical circuits

has some 13,600 miles of fine hair-like insulated iron wire 1/1000 of an inch in diameter, in association with it for the magnetic cores of its loading coils.

Simply to string this immense amount of wire across the continent, to set the poles and insure insulation, to conquer the innumerable difficulties offered by land, water, forests, mountains, desert, rivers and lakes, was in itself a task of no mean magnitude.

But a still greater task has been the building of the human organization that maintains the line day by day in operative condition and that maintains also the millions of active telephone terminals spread from ocean to ocean, without access to which the copper of the transcontinental circuits might as well be back in the mines from which it came and the poles back in their original forests. No group of isolated companies could build a transcontinental telephone line, or, if it were once built, could maintain it for a week in operative condition. The single-minded purpose that caused the line's construction must operate with equal singleness of mind each minute and each hour of the day to maintain it in service.

Such an organization, also, and all of the many similar organizations that are lending themselves in good spirit to the public service must have the wherewithal to work, the assurance of reasonable profits and public good will and co-operation to-day and for the future, if they are to do the great constructive work that the nation demands.

For a final word, it is something more than a pet phrase to say that, in this country, we need only transmission—not translation. Differences in language are vital things. The great European conflict is perhaps even more a war of languages than it is a war of peoples and dynasties.

It may be an extreme statement to say that if we had had a national telephone system before 1860, the Civil War would not have been fought, but it is probably true that the railroads, the new canal, and our universal telephone service have all combined to weld our people together in a lasting unity.

FOREIGN REVIEW AND REVIEW OF THE PROCEEDINGS OF ENGINEERING SOCIETIES

At a meeting of the Council on October 8, 1915, it was voted to approve the recommendation of the Publication Committee to include in The Journal a review of the world's technical press. In accordance with this resolution, the Engineering Survey will contain, in the future, in addition to the material as hitherto published, abstracts from engineering publications in the English language. This feature will be developed gradually, however, beginning with the publication of a few abstracts in each issue, selected with a view to placing on record the more important developments in mechanical engineering.

ENGINEERING SURVEY

In engineering, there are still a good many "traditions" which have been accepted some time in the past and persist mainly because a general impression prevails that the thing is right and is therefore to be accepted by everybody as being right. This condition continues until some one takes the trouble to investigate when and how such a law or rule was proved to be right, in which case it often develops that it never was proved to be right, and that it is, in fact, entirely wrong. Such a situation existed in the early days of electrical engineering, when, with respect to direct current motors, there was a sort of accepted dogma to the effect that the external resistance should be equal to the internal resistance: This held the efficiency of the generator down to about 40 per cent. Then came Thomas A. Edison, who stated that he did not see why the internal resistance should be so high; that what he wanted was to deliver current outside and not inside. The Jumbo was built and showed an efficiency of over 80 per cent. Apparently similar considerations led to the assumption that a valve on an air compressor or pump will close without shock if the closing occurs exactly at the dead point in the motion of the piston. As a matter of fact, this is not only practically impossible, but theoretically wrong, and in order that the valve should close free of shock, the closing must occur *after* a reversal in the motion of the piston. This, and several other considerations of a very interesting nature, are brought out in the article on the analysis of the motion of valves, by Klepal, in this issue.

THIS MONTH'S ARTICLES

In the section, Aeronautics, are abstracted two interesting articles—one of direct practical importance, on aeronautical timber, by J. E. Huson, in which the author, among other things, calls attention to the great variation in the mechanical properties of timber, depending upon the original size of the log, time of felling, interval between felling and sawing, and the position of the test pieces relatively to the heart of the tree. The other article in the same section refers to the application of the law of similarity to balloon models, and among other things, brings out the importance of the variation of the coefficient of air resistance with the nature of the surface of the body moving through the air.

A description of an improved type of suction producer gas locomobile is given. Its main feature is an arrangement permitting the separation of the cooler from the producer and, as a result, a far more effective cooling than has previously been obtained on locomobiles of this type.

An extensive and well illustrated abstract of an article on German apparatus for the measuring of pressure and velocity of gases will be found in the section on Measuring Apparatus. The question of apparatus of this nature became of particular importance in Germany since the adoption by the German Society of Engineers, of the standard rules for testing air compressors and blowers.

An article on the holding power of nails is abstracted indirectly from the Indian Textile Journal.

In the section, Steam Engineering, are described some tests of a 300 h.p. superheated steam locomobile, of interest because it shows a comparatively low fuel consumption and the ability of the plant to carry a very large overload. A brief description of an improved dry back marine boiler and some data of tests of same are given.

A description of a laundry for the handling of ships' washing is abstracted from a German publication.

In a paper before the American Society of Civil Engineers is described the automatic volumeter, an apparatus intended to gage the flow of fluids by the collection of a proportional part of the flow, or its equivalent, in a small vessel where it can be readily measured at any time. In order to design this apparatus, the coefficient of flow through small orifices had to be established, and experiments along these lines, partly reported in the abstract, have revealed totally unexpected conditions. These experiments were made both with water and with oil.

Professor G. L. Larson, in a paper before the American Society of Heating and Ventilating Engineers, reports tests on the recirculation of washed air, in which, among other things, he calls attention to the fact that recent investigations (some of which have been reported in the Engineering Survey), have shown that what is known as bad air is caused preeminently by the physical conditions of the air with respect to temperature, humidity and movement. It is both unnecessary and uneconomical to supply large volumes of air in order to obtain good ventilation. Carbon dioxide as high as 20 parts of 10,000 does not have a bad effect upon ventilation, and ventilation by recirculation is both efficient and economical.

An important series of tests on the shearing resistance of reinforced concrete beams is published in the Transactions of the Canadian Society of Civil Engineers. Of especial interest is the establishment of the fact that stirrups tend to quite materially raise the ultimate strength of the beam and that when they are set 4 in. apart, shearing failure is practically eliminated.

From the Memoirs of the College of Engineering of the Imperial University of Kyoto, Japan, is briefly abstracted a

paper on the Leonard control applied to mine hoists, of interest because it gives general equations of the resisting moment of hoist as well as equations from which may be found the mechanical relations between acceleration and retardation.

The Purdue Engineering Review reports some tests of standard and clasp brake rigging for passenger train service, made lately on the Lake Shore and Michigan Southern Railroad, and indicating that on the whole, the clasp type of brake is the more proper design to use for heavy passenger equipment.

Vulcanizing experiments on plantation Para rubber, made at the laboratory of the Department of Agriculture of the Federated Malay States, indicate that if the rate of cure be known or ascertained under specific conditions, vulcanized rubber having similar chemical properties, can be made from all good samples of "first latex" rubber so that both plantation and wild rubber may be used equally well. The same tests have established the fact that the rate of cure itself is due to the presence of some substance in the latex, which probably acts as a catalyst and accelerates the rate of cure. The paper suggests the issuance of certificates giving the correct rate of cure and mechanical properties at that cure.

From the bulletin of the University of Illinois are reported experiments made for the purpose of determining the influence of temperature on the strength of concrete.

Aeronautics

AERONAUTICAL TIMBER, J. E. Hanson

The paper discusses the question of the use of various timbers for aeroplane construction from a purely technical point, without regard to the special conditions of supply created by the current events in Europe.

The natural fallacy in considering timbers which besets engineers used to calculations in metals is the unconscious assumption that all perfect specimens of timber are homologous, which is by no means the case. A flawless piece of ash sawed from the outside of a tree will vary in specific gravity, tensile strength, elasticity, etc., from a piece of the same log sawed nearer the heart and both would differ from timber riven instead of sawed. Timber sawed from young trees would differ from that obtained from older trees grown in the same locality. Timber only partially seasoned gives different values from timber "bone dry." Ash grown in sandy soil differs from that grown on a clay or chalk soil and that grown in a coppice from that in the open field. That grown at a high altitude and bleak aspect differs from that in a lower and more genial position.

Tables of tests therefore are to be handled with caution and their information would be more valuable if they were supplemented with full descriptive notes as to the region, original size of log, when logs were felled, interval between the felling and sawing, how long in the stick after sawed, and the position of the test pieces relatively to the heart of the tree.

Two important points should be steadily borne in mind: *first*, that timber is mainly a natural growth and therefore varies with all of the many factors affecting growth, and *second*, that time is an essential factor in proper seasoning. When ordering timber for aeroplanes, it should be remembered that the smaller the dimensions asked for, the greater the choice of timber for quality and no attempt

should be made to get large planks of such a size as will cut economically for two or three different sizes.

It is much more difficult to obtain ash straight in the grain for a good length than it is to procure silver spruce absolutely straight. Further, there is a greater variation in the properties of ash than there is in those of silver spruce; hence, when designers have the option of specifying silver spruce or ash, and can afford the extra bulk and increased head resistance to bring the strength of spruce up to that of ash, it would seem prudent to prefer the former.

As to hickory, although the best grade is stronger than the best ash, yet it is a wood which varies considerably and it is doubtful whether on the whole, weight for strength, it has any advantage over ash. It is, however, extremely tough and is probably the best wood for skids. It should not be used in hydroplanes as it is subject to rot in water.

The writer does not recommend kauri pine for aeroplane work. It is extremely liable to be knotty, is heavier than silver spruce and inferior to it in physical properties. Rock elm has no advantage over ash in strength and other properties and has the disadvantage of being usually sold in solid logs.

Mahogany is used by two or three contractors. In working out designs it should be borne in mind that the actual thickness of mahogany is a saw-cut less than the normal thickness. It is valuable in that it is not affected by water and if carefully chosen should be a very good wood for aeroplane work.

Yellow cedar will not rot in water and hence it is suitable for hydroplane boats. Parang is a species of mahogany, stronger and more fibrous than the Honduras variety. It has been used for dirigible propellers. Teak is a highly suitable wood for workings in hot climates. Oak is not used in aerial construction (*Aeronautics* (London), vol. 9, no. 102 (new series), p. 219, September 29, 1915, 2 pp., pp).

LAW OF SIMILARITY AND BALLOON MODELS, C. Wieselsberger

At the Model Testing Laboratory of Aeronautics connected with the University of Göttingen, a series of tests have been carried on for some time on the application of the law of similarity to the case of balloon models and on the influence of the nature of the surface of the model on the air resistance. In this article are described tests on four models, the purpose of which was to establish, *first*, the applicability of the law of similarity in general, and *second*, the variation of the coefficient of air resistance with the nature of the surface.

The four models had the general shape shown in Fig. 1A, having been made by electro deposition of copper. The surface was carefully smoothed with emery and then covered with a layer of japan varnish so to prevent oxidation. The midship diameters were respectively 93.6, 132.1, 188.7 and 268.8 mm. (3.68, 5.13, 7.42 and 10.58 in.). Measurements were made in an air stream having velocities up to 23 m. sec. (75.46 ft. per second). The data of these tests are shown in Fig. 1B, by the full drawn lines, the coefficient of air resistance ψ being plotted as a function of the Reynolds coefficient,

$$R = \frac{vd}{\nu}$$

In accordance with the law of similarity, the coefficients of resistance of all models ought to lie on a single curve. Actually, however, each model seems to have a curve of its

own, which is principally due to the fact that it proved to be impossible to construct models absolutely similar to one another, and there are, in each case, slight deviations from the accepted shape. Experiments have shown that these deviations have an unexpectedly great influence on the resistance of the body. It has been further found that the coefficient of resistance rapidly decreases with the increase of the Reynolds coefficient, but when the Reynolds coefficient becomes very large, an increase begins in the coefficient of air resistance. The strong decrease of the coefficient of resistance with the increase of air velocity corresponds to the transition from a laminar to a turbulent flow and when the Reynolds coefficient exceeds 200,000, the flow is dis-

est velocity available. Next the cloth-covered model was treated by the Cellon-Emaillit process as usually applied to aeronautical cloth (this process usually requires the application of three layers of Cellon-Emaillit A, which is then rubbed off by fine sandpaper, after which two layers of Cellon-Emaillit B are applied). This treatment reduced the resistance to still lower values than had the models with smooth copper surfaces. Next, the models so treated were provided with a layer of High-Brilliance Emaillit varnish, which gave them a mirrorlike surface. A further reduction of resistance was obtained, within the region of velocities available, only with the Reynolds coefficient below 160,000, but at higher velocities the ϕ curve rises again somewhat.

In the next article, the same author describes investigations on the measurement of air resistance in a free air stream and in a tunnel with circular plates and flat planes (*Mitteilungen aus der Göttinger Modellversuchsanstalt, Zeits.*

FIG. 1. RELATION BETWEEN NATURE OF SURFACE OF BALLOON MODEL AND AIR RESISTANCE

tinctly turbulent. The velocity of air could not be reduced sufficiently to obtain values of ϕ for the laminar state.

The models were then covered by balloon cloth with the rough non-rubberized side upward, and the resistance measured anew. The data of these measurements are indicated in Fig. B by the broken lines. It was not to be expected that the law of similarity would hold for this case since the roughness of the surface could not be geometrically the same for all the models. What is remarkable, however, is the entirely different shape of the ϕ curves, which in this case rapidly increase with the increase of the Reynolds coefficient and assume an irregular wave-shaped formation.

The influence of the nature of the surface was further investigated on one of the models (No. III): first the bristling fibres on the surface of the model were burned off by a rapidly moving flame and the resistance then determined. The result was very remarkable (Fig. C'). The coefficient of resistance which was formerly quite small at low velocities, increases to two and a half times at the great-

Internal-Combustion Engineering

LOCOMOBILE DRIVEN BY SUCTION PRODUCER GAS, Gwosdz

Description of an improved modern type of suction gas producer locomobile built by the machine factory of the Royal Hungarian State Railways.

The important requirement in the design of a suction gas locomobile lies in compactness of arrangement of the main elements of the plant: i.e., the gas producer, cleaner and engine. In older designs, the producer and gas cleaner were located in the same shell, which served also as a support for the engine. In addition to the fact that such a construction made access to the gas producer in case of repairs considerably more difficult, there was also the disadvantage that the cleaner, which had the duty of not only cleaning the gas, but also of cooling it, was too much exposed to the heat from the gas producer and received the gases at too high a tem-

perature, which increases the difficulty of cooling. The next step was to arrange the producer and cleaner separately, but even here they were so close together that a free cooling of the gas before entering into the cleaner did not prove feasible.

The Machine Factory of the Royal Hungarian State Railways has placed on the market two designs, in both of which

(the latter has an annular shape and is placed around the evaporator *c*). The gas is first cooled to quite a considerable extent in this connecting pipe, and also by contact with the front wall of the cleaner, likewise exposed to the atmosphere. This boiler wall is also part of the entrance chamber *e*, which on the other side is separated from the washing chamber by a wide wall, *f*, ending in a sharp edge

FIG. 2 IMPROVED SECTION PRODUCER GAS LOCOMOTILES

the above difficulties are said to have been obviated. The first of these designs is shown in longitudinal section in Fig. 2A. The producer *a* and the engine are located on separate under frames, with the engine lying directly on the flat cooling and cleaning shell *b*. The producer is separated from the cleaner by an intermediary space, fully exposed to the atmosphere, and connected with it by a wide conical pipe *d*, which branches off at the level of the gas collector

and coming down to nearly the water level. From the entrance chamber, the gas goes to two scrubbers *g*, and from them, through a dryer *h*, filled with wood fibre, to the gas engine. The water which collects in the cleaner is allowed to escape through the overflow pipe to the trap *k*. On the front side of the gas producer there is located a hand driven fan for blowing the fire. All the cleaning chambers have side openings, closed by tight covers.

As fuel, coke, anthracite and charcoal may be used. With the latter, the attendance is especially simple and the cleaning is no more trouble than with a gasoline engine. This is due, of course, to the low ash content and the easy gasification of the charcoal. The favorable experience in running a producer on a suction gas locomobile with charcoal led to a still greater simplification of the cleaner.

In the design, shown in longitudinal section in Fig. B, the cleaner no longer supports the engine frame, but is a separate container located between the gas producer and engine frame, so that the gases in passing through it encounter considerably less resistance than in the former design. The gas producer *a* is suspended in the front part of the frame, and the gas passes from it through pipe *b* into the container *c*, located between the U-shaped beams of the frame. In the angle arm between pipe *b* and container *c* is built in the cooling water pipe *e*, provided at the opening with a nozzle *f*. The container *c* is equipped in its lower part with an overflow pipe *g* and sieve-shaped wall *h*. The latter is passed through in the middle by the tube-shaped drying tank *i*, located concentrically to the sides of the walls of the container *c*, this drying tank *i* being in its turn built in its lower part like a sieve. The top is connected by an elbow element, *k*, to the rear wall of the container *c*, and is connected with a long transmission pipe *l*, leading to the cylinder head of the engine. Container *c* carries both sieve *h* and some filtering material (coke) and the dryer space, *i*, is filled with clean iron filings.

The gas flowing through the bend *d*, goes therefore to the upper chamber of the container *c* through a sheet of water, and in doing so is effectively cooled. After it has passed through the coke filter of the scrubber and then through the dryer, it goes to the pipe *l*, in which it is further cooled on its way to the engine. This simplification of the cleaner and cooler results in a reduction of the power consumed in the suction. (*Neue Sauggaskomobilen*, Gwosdz, *Zeits. für Dampfkessel und Maschinenbetrieb*, vol. 38, no. 49, p. 329, October 1, 1915, 3 pp., 3 figs., *d*).

Measuring Apparatus

GERMAN APPARATUS FOR MEASURING PRESSURE AND VELOCITY OF GASES, E. Stach.

Descriptions of various apparatus for the measurement of pressure and velocity of flow of gases.

The simplest and most widely used apparatus for measuring pressure in gases is the vertical U-tube with alcohol or water for low, and mercury for average pressures. In order to increase the movement of the column of liquid there may be used two liquids of different densities as shown in the apparatus of Dr. Rabe, Fig. 3A. The liquids differ here both in specific gravity and in color and their dividing plane forms the zero point. Because of the displacement of the level of the liquid under pressure on the side of the lighter liquid, the displacement of the dividing plane is influenced by the ratios of cross sections and specific weights and, generally, dimensions and liquids are so selected that the deflection is at least twice as great as it would be with a water column. In order to throttle the movement of the liquid and to reduce the tendency of the two liquids to mix under strong variations of pressure, there is produced in the right hand tube of the apparatus a throttling by means of the glass ball *c*. When the pressure to be measured is above atmospheric the apparatus is connected at *a*, and when below atmospheric, at *b*.

Another apparatus, for fine measurements of pressures from $+0.01$ to $+25$ mm. of water, is diagrammatically shown in Fig. B. The vessel which contains the measuring liquid (distilled water) is divided by a partition into two airtightly separated chambers *a* and *b*. When a pressure above atmospheric is measured, the connection is made at *d* and for measurements of pressures below atmospheric, at *e*. By means of a millimeter screw provided with a measuring wheel divided into 100 parts, the needle *s* can be screwed down until the galvanoscope *f* shows a deflection. Full millimeters are to be read on the scale *m* and fractions on the micrometer. The apparatus must be protected from vibration.

A manometer for fine measurement of fluctuating pressures is shown in Fig. C. It has a vertical measuring tube and is filled with absolute alcohol. It consists of a wide vessel made of cast iron provided with hose connections and a vertical stand pipe. Between the vessel and pipe there is located a cock shown in the front part of the drawings, by which may be effected either a direct connection or one through narrow brass tubes of different lengths located under the vessel. These last tubes act as a damper of the fluctuating deflections of the apparatus in accordance with their length which in its turn depends on the position of the cock. At first the pressure is connected without any damping and the oscillations are then quieted down by means of a gradual insertion of tubes of various lengths, whereupon rapid and correct reading of pressure can be taken. The reading is done through a small magnifying glass located adjustably on a laterally held bar. With this magnifying glass is connected a little mirror, giving an inverted image of the meniscus. A fine adjusting screw is moved until it appears through the magnifying glass that the tip of the screw and the image of the meniscus touch each other. The reading is actually effected by means of a nonius and magnifying glass on a micrometer scale divided into fractions of a millimeter. For measuring average pressures, both above atmospheric and vacua, mercury filled manometers constructed on the principle of a barometer are mainly used. Fig D shows such a vacuum gage built by R. Fuess. The sign "Marke z" indicates the exact level of mercury when the gage is not connected. The connection between the glass tube and screwed pipe-joint *mr*, which leads to the condenser or a similar apparatus, is made by means of a heavy hose *s*. The left tube (with the scale) is not as long as a barometer, since usually, for example in condensers, vacua from 60 per cent. on are of interest only. The scale to the left reads in millimeters of mercury, and to the right in absolute pressures. For gage pressures above atmosphere, such as occur for example with blowers, the left part is also made like a barometer tube, but of a length of about 1.6 m (41.7 in.) and pressures are likewise given in absolute units. For reading very low pressures, a so-called micromanometer is used, which is usually equipped nowadays with an adjustable reading tube and either a variable or a permanent zero point. The article describes the micromanometer of Recknagel and Berlowitz. They are not described as another micromanometer (Fuess) has already been described in *The Journal*, (October, p. 194).

Indicating and Recording Pressure Gages: The older types are described, such as the Oelwaldt gage. Of greater interest is the gage designed by de Bruyn, Fig E, and the line of apparatus built by the Hydro-Apparatus Company. As shown in Fig. F, in the latter motions of the float are

transferred to the indicator hand in the same way as in a spring manometer. In Fig. G is shown a combination of a recording pressure gage and a differential draft indicator. The recording of the differential draft with simultaneous re-tension of the indicating scale has been secured by raising the diagram drum and providing a second scriber. If it is

and below it, due to the reversal of the valves of the chambers. For the variation of pressure above and below atmospheric, alternating by about the same amount, the zero point is located in the middle of the diagram. The section of such a diagram is shown in Fig. K. The abscissae give the times and the ordinates, pressures ± 50 mm. of water. The nearly

FIG. 3 A, RABE DRAFT GAGE; B, G. A. SCHULTZE PRESSURE GAGE FOR FINE MEASUREMENTS; C, PRANDTL MANOMETER FOR MEASURING FLUCTUATING PRESSURES; D, R. FESS VACUUM GAGE; E, DE BRUYN PRESSURE RECORDING GAGE; F, HYDRO PRESSURE GAGE; G, HYDRO PRESSURE INDICATING AND RECORDING GAGE; H, PRESSURE RECORDER FOR SIX POINTS OF MEASUREMENT; K, DIAGRAM OF A PRESSURE RECORDING GAGE ON AN OPEN-HEARTH FURNACE

required to record the pressures from several points of measurement, the gage shown in Fig. H (for six points of measurement) can be used. It is self-explanatory.

For measurements on regeneration firing plants, such as open-hearth furnaces, coke ovens and glass melting furnaces, it is important to be able to record the time sequences as well as the height of alternating pressures above atmospheric

vertical lines indicate the times of reversal of the gas or air valves.

The article also describes the pressure recorder of de Bruyn for high pressures. (*Messgeräte für Druck und Geschwindigkeit von Gasen*, E. Stach, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 41, p. 832, October 9, 1915, article not finished, d).

Mechanics

ANALYSIS OF THE MOTION OF SUCTION AND PRESSURE VALVES,
O. Klepal

The motion of a valve embraces four stages: 1. Opening of valve; 2. Forward motion, away from seat; 3. Backward motion, toward seat; 4. Closing. In theoretical investigations it has hitherto been the practice to treat the stages 1 and 2 combined, but the author proposes to show that this method of procedure is not correct and may lead to wrong conclusions.

The opening of the valve is brought about by the motion of the piston. In order to overcome the pressure p , over the area F , above the valve (Fig. 1), the motion of the piston must exert below the valve a pressure p_1 , which may be calculated from the equation

$$p_1 = p \frac{F}{F_1}$$

where F and F_1 are valve areas above and below. To this must be added the pressure required for the acceleration of

FIG. 4A VALVE MOTION DIAGRAM FOR PUMP

the valve mass, for lifting the weight of the valve (when the valve moves vertically) and for overcoming the friction at rest in the valve guides, together with overcoming resistance, due to the action of the valve springs. The difference in pressures $p_1 - p$ must be as small as possible. This presupposes narrow valve seats, and small weight and mass of valves as well as small friction and the balance of the mass.

Up and Down Motion of the Valves: After the pressure below the valve has forced an opening and a slit is formed between the seat of the valve and its cone, there commences a flow of fluid (either in drops or as a gas), through the cross-section F , this flow proceeding with a velocity which increases with the increased velocity of the motion of the piston (upward stroke) and decreases with its decrease (downward stroke). There act, at any point of its path h (valve stroke) on the area of the valve, the following main and auxiliary forces:

Main Forces

- a Impact of the stream of fluid P (called in the discussion following, "stream impact").

- b In the case of valves loaded by springs, the force of the spring P' acting in the opposite direction.

Auxiliary Forces

- a In vertically moving valves, the weight on the valve G .
- b The friction in the valve guides $\pm R$, which acts always in a direction opposite to that of the motion of the valve and therefore changes its sign.
- c The force $\pm B$, which produces acceleration of the mass of the valve and is supplied on the upward stroke by the stream impact and on the downward stroke by the valve

FIG. 4B VALVE MOTION DIAGRAM FOR AIR COMPRESSOR

spring. Hence, to the upward stroke of the valve applies the equation

$$P' = P' + R + B + G \dots \dots \dots [1]$$

and for the downward stroke of the valve

$$P + R + B = P' + G \dots \dots \dots [2]$$

In the above equations, P , P' and B are variable, R may be assumed to be constant, and G is constant. G may be assumed to be known, as it depends entirely on the design of the valve. All the other variables are dependent on the magnitude of the stream impact and for the present this essential for the knowledge of the valve motion element is taken to be unknown, and the author considers it quite problematic whether its value can be at all established with a precision sufficient for practical purposes. If it can be done, it will require extensive and costly experimentation.

In this connection the author quotes what Professor Körner wrote in 1908 (*Zeitschrift des Vereines deutscher Ingenieure*, page 1842 and following): "Even with stationary valves and very simplifying assumptions, the direct analytical determination of the pressure (stream impact) exerted by the stream of water, presents insuperable difficulties. My experiments in this connection have not resulted in obtaining values which would be sufficiently complete and in agreement with the actual values, even though a certain functional dependence could be found. Still less soluble proved to be the problem when the motion of the valve itself exerted an influence on the pressure to be determined and hence, this method of research had to be abandoned."

It appears, therefore, that the magnitude of the stream impact cannot be determined by calculation. It may, however, be found graphically. Let F represent the area of the piston in cm^2 , f , the area of free passage of the valve in cm^2 ; maximum v , the greatest piston velocity equal to the velocity of the crank pin in m ; maximum u , the greatest velocity in the valve cross-section which can be calculated

$$\text{from the equation: } \max u = \frac{F \cdot \max v}{f} \text{ in } m \dots \dots \dots [3]$$

It will be assumed for the present that the magnitude of the stream impact is proportional to the square of the instantaneous velocity in the valve section. In Figs. A and B, the magnitude of the stream impact is represented separately for liquid pumps on the one hand, and compressors, air pumps and blowers on the other, respectively.

In correctly working pumps, it has hitherto been assumed that both the suction and the pressure valves remain open or closed during the entire stroke of the piston and that the stream impact acts on the valve during the entire stroke. It will be seen that this view is only approximately correct. Of decisive value so far as the motion of the valve is concerned is, however, the operating pressure and its influence will be here considered. In the case of pumps, compressors, etc., we have to distinguish two kinds of working pressures: *the working pressure exerted on the suction valve, and that with which the pressure valve is working.* Usually, except in the case of multi-stage compressors and air pumps, the working pressure at which the suction valve is operated, is approximately equal to atmospheric in the case of a compressor and is below atmospheric with pumps, in accordance with the suction head. Because of the final width of the valve seat there must be in the working cylinder above the suction valve a pressure below atmospheric which produces the opening of the valve. When the valve is lifted, the pressures above and below the suction valve are equalized and the suction pressure ceases to act on that particular valve.

The processes in the pressure valve occur in exactly the same manner. In the working cylinder, because of the final width of the seats, there must exist a pressure above atmospheric as is shown in equation [1]. Here again, when the valve lifts, the pressures equalize and the working pressure then prevailing no longer exerts any action on the lifted valve. In both cases, with the suction as well as with the pressure valve, the opening of the valve occurs *after* the piston passes its dead center; and not, as has hitherto been assumed, exactly when it is in dead center. The latter would involve an assumption of an infinitely narrow valve seat area, which is impossible to attain in practice. The recognition of this fact is of importance for our further investiga-

tion, viz., for the determination of conditions of quiet valve play.

In Fig. 4A, in the lower part, is given a theoretical indicator diagram of a pump (a rectangle). In this and in the following figures, at is the atmospheric line and vt the line of the absolute vacuum. The ellipse E represents piston velocities with infinitely long connecting rods and maximum piston velocity $\max v$ in the middle. From equation [3] can then be calculated the maximum velocity of the fluid in the valve cross-section, $\max u$, and its square plotted in Fig. A. The other points of the curve E , the ordinates of which represent the magnitude of the stream impact acting on the valve area at any point of the piston stroke, are calculated from the equation

$$u^2 = v = \max u^2 : \max v,$$

or

$$u^2 = \frac{v \cdot \max u^2}{\max v} \dots \dots \dots [4]$$

The values thus calculated, when connected by a smooth curve, give the curve E_s , which, together with the horizontal line below, encloses an area which represents the power transmitted to the valve area during one valve stroke. Its area is sectioned. The meaning of the black strip will be explained later.

In compressors, air pumps and blowers, the amount of power transmitted to the valve area is different for suction and pressure valves and in addition to that depends on the working pressure. In Fig. B in the middle is represented a theoretical indicator diagram of the compressor. After the expansion of the gas in the clearance space, the suction valve, because of the existence of the pressure below atmospheric in the working cylinder, opens theoretically at the point of intersection b of the expansion line of the clearance space with the atmospheric line at ; the gas flows into the cylinder and its impact lifts the valve. The amount of power from the stream impact, transmitted to the valve area, is represented in Fig. B, at the bottom, by the area enclosed by the curve E_s , the vertical line at b and the horizontal line below. This area is likewise sectioned, and the meaning of the black strip will be explained later. In a similar manner has been determined the amount of power transmitted from the stream impact to the pressure valve (see Fig. B, top). The area is a section and the curve E_s has been determined in the same manner as in the case of the pump. The points b and c shift in accordance with the working pressure of the compressor and this causes a change in the power supplied by the stream impact.

From what has been said above, it appears that the action of the stream of fluid on the valve occurs not at the dead center of the piston, with pumps, and at points b (suction valve) and c (pressure valve) with compressors, but somewhat after that. The importance of this fact will appear later.

If the magnitude of the impact stream could have been analytically computed beforehand, the dimensions of the machine and the speed at which it will run would predetermine the required loading of the valve. In the case of spring loaded valves (hence, valves without rigid limitation of the length of the stroke which is in this case elastic), the opening of the valve lags behind the dead center of the piston and occurs without shock. The shock in the valve motion can occur only when the valve hits the seat. The opening of the valve and its forward and backward motion occur

without shock. If, now, we investigate the conditions under which a free-of-shock closing of the valve occurs, we see the following: *the action of the stream of the fluid ceases exactly at the instant of reversal of the motion of the piston.* At the same instant, and hence theoretically within an infinitely short time, the valve must close, which would require a theoretically infinitely great closing force necessary for the acceleration of the mass of the valve, and this is practically impossible. Hence the closing of the valve cannot take place when the piston is at its dead point and the closing of the valve before that instant is likewise obviously out of the question. The opening of the valve without shock occurs after the reversal of the motion, since it cannot be otherwise as the action always follows the impulse.

Vice versa, a shock-free closing of the valve may be expected if it occurs after the reversal in the motion of the piston and hence not, as has hitherto been assumed or striven after, exactly at the dead point in the motion of the piston. The valve closing must occur after the reversal of the piston, since action always lags behind the impulse, and in this particular case the acting force is the stream impact. Beside, to the case of the free-of-shock valve closing applies the same rule as to all other motion which occurs free of shock—to wit, the sum of all forces or works occurring during the motion must be, at the beginning and at the end of the motion, equal to zero.

Let us now follow up from Fig. A the motion of the suction valve.¹ The valve rises with the increase in the piston velocity up to the highest point of stroke; then its stroke decreases up to the dead point in the motion of the piston. Let us imagine that the valve, at the dead point of the piston, is not yet quite closed and that between the valve and its seat there is a tiny slit. Then, at the instant of the reversal of the piston, the liquid begins to flow back through that slit, the stream impact changes its direction and helps to close the valve. Simultaneously, at the reversal of the piston, there occurs in the working cylinder a slight increase of pressure above atmospheric, since in the slit between the valve and the seat the liquid is throttled. There is, therefore, a small difference in pressure between that above and that below the suction valve, which, together with the reversed stream impact, forces the suction valve against its seat. To the negatively acting (as far as the direction is concerned) stream impact, and the closing pressure of the liquid, there must be opposed a negative load on the valve, produced by the spring. In other words, the valve must be loaded negatively (in the direction away from the seat).

If we denote the pressure above atmospheric above the valve by D , then the equation [2] for valve closing will have the following form:

$$P + G + D = P' + R + B. \dots \dots \dots [5]$$

or

$$P + G + D - P' - R - B = 0. \dots \dots \dots [6]$$

This equation can be constructively satisfied by proper appliances, and with it can be satisfied the conditions of shock free valve closing; viz., that the sum of all forces or works at the end of the valve motion be equal to zero. How this is done may be seen from Figs. A and B.

The opening of the valve in Fig. A lags behind the dead point of the piston by the time Δt ; the valve closing lags be-

hind the other dead point of the piston by the time Δt . In accordance with this, the cross-sectioned area representing the work of the stream impact is reduced by the little black area having the abscissa Δt . Because of the reversed flow of the liquid, there occurs on the left side a negative working of the stream impact, which is limited by the abscissa Δt and by a part of the curve E_s . The curve E_s is the same as the curve E_p , but, in accordance with its negative sign, is curved downward. In the case of pumps handling liquids, the above applies to both valves.

In compressors, air pumps and blowers, the suction valve indicated in the lower part of Fig. B opens not at the point b , but at b_s , lagging by the time Δt , and the work of the stream impact is reduced by the amount of the black strip. The valve closing, lags behind the dead point of the piston by the time Δt . The negative working of the stream impact is limited by the abscissa Δt and the curve E_s and is marked in black.

The opening of the pressure valve occurs not at the point c , but lags behind it at the point c_s ; the working of the stream impact is reduced by the black strip (Fig. B, upper part). The valve closing occurs behind the dead point of the piston and the negative work is marked in black (*Betrachtungen über die Bewegung der "freigängigen" Ventile*, O. Klepal, *Die Fördertechnik*, vol. 8, no. 19, p. 145, October 1, 1915, 6 pp., 8 figs., *td*).

THE HOLDING POWER OF NAILS

The subject of the holding power of nails in wood, and especially in hard wood, does not appear to have been sufficiently investigated and the information contained in the present abstract may therefore be of particular interest.

As the writer states, a glance at the interior of any coasting boat will show that although every nail is clinched and a length of 3 in. is allowed for that purpose, while the spread of the head barely amounts to 1 in., the waste of iron in nails alone cannot be less than from 20 to 25 per cent.

A nail holds itself in place in two ways; by friction of its sides against the wood, and when clinched, by the resistance of the clinch, which resembles a second and smaller head. Square nails are usually tapered on two sides and straight on the other two sides. The tapered sides should bear against the end grain of the wood, crushing it gradually as the nail enters. All woods, when soaked in water or when green, may be nailed with less risk of splitting than when they are dry, but there are limits to the depth that a long nail may be driven into any wood before it begins to bend. When a nail begins to bend, it shows that a hole must be made beforehand. The object of the hole is to reduce the friction so as to allow the nail to be driven without bending, but if made too large, the holding power of the nail will be reduced and clinching will be a very imperfect remedy.

If many nails of one size have to be driven, as in boat building, it is advisable to experiment on a piece of wood of the necessary thickness in order to find out the right size of hole that will avoid splitting the wood or bending the nail. When wire nails of a large size are to be clinched, they should be softened at the point by heating to redness. A wire nail is hard drawn to enable it to be driven without bending in soft woods, but it does not clinch well for this reason and therefore needs softening. To ascertain the holding power of a nail, it may be driven into an upright post, leaving the head projecting just enough to be seized by a

¹ This refers apparently to pumps handling liquids.

nail-puller. This instrument is then attached and weights added to the outer edge until the nail begins to move.

Nails that have rusted after being driven have an increased holding power, but if rusted before use they tend to make a slightly larger hole than a smooth nail. In cases where clinching would be liable to split the wood, nails may be cut and riveted over a small washer, which makes a strong and durable joint. There is also a way of clinching a nail within the wood. The point is filed away on one side to a wedge shape and then bent over the filed part until the point is level with the side of the nail. The hole is drilled to the size of the nail which is inserted with the filed surface parallel to the grain of the wood. When driven, the point takes the form of a hook and has a strong hold on the wood. The point of this nail should be heated and softened so as to facilitate the turning of the point.

Nails driven in wood that is exposed to alternate wetting and drying are liable in time to work loose because the wetting swells the wood and increases its dimensions around the nail, and as the nail is non-elastic itself, a compression is formed at the point of the nail to the amount of the swelling of the wood. When the timber dries again, the nail does not return to its original place, and if tapered, it tends to draw outward every time the wood is wet and dried. (*The Canadian Engineer*, vol. 29, no. 18, p. 519, October 28, 1915, abstract from the *Indian Textile Journal*.)

Steam Engineering

DRY BACK MARINE BOILER. Arthur C. Meyers

Description of an improved marine boiler designed to obtain better circulation.

To accomplish this, a tube sheet was fitted in the rear end of the furnace and the furnace connected with the combustion chamber by 4 in. tubes. It was expected that this would set up a more rapid circulation than was possible by the usual method of attaching the furnace directly to the combustion chamber. Short tests were made to determine the capacity of the boiler, but the shell was not insulated and the feed water was very low in temperature (45 deg. Fahr.). The data of tests are given in Table 1. Natural draft was used, the stack being 40 ft. high and 18 in. in diameter (*International Marine Engineering*, vol. 20, no. 11, p. 511, November, 1915, 2 pp., 1 fig., de).

TABLE 1. TEST OF AN IMPROVED MARINE BOILER

Duration of test.....	1 hr. 34 m. 35 s.
Grate Surface.....	85 sq. ft.
Heating Surface:	
Furnace crown.....	21 sq. ft.
19 4-inch tubes 12 in. long.....	18.52 sq. ft.
41 3-inch tubes 6 ft. 8 in. long.....	199.72 sq. ft.
Back tube sheet (effective).....	3.45 sq. ft.
Total Heating Surface.....	242.79 sq. ft.
Ratio H. S. ÷ G. S.....	2.839
Average Steam Pressure by gage.....	95.95 lbs.
Average Steam Pressure Absolute.....	109.75 lbs.
Average temperature of Feed Water.....	45 deg. Fahr.
Total water fed to boiler during test.....	1,845 lbs.
Total water fed to boiler per hour.....	1,165 lbs.
Quality of steam, per cent.....	97
Water evaporated per hr., corrected for quality.....	1,139 lbs.
Factor of evaporation, $\frac{1,139}{(11 - (t + 32))}$	1.212

Where H = total heat of steam at 109.75 lb. absolute = 1,183.9.
t = average temperature of feed = 45 deg. Fahr.
Water evaporated from and at 212 deg. Fahr. = $1,139 \div 1.212 = 1,593.95$.

TESTS OF A 300 H.P. SUPERHEATED STEAM LOCOMOBILE

The article describes tests of a 300 h.p. superheated steam locomobile plant made, first, at acceptance and then, after the plant had been in operation for two years.

The plant comprises a double-expansion superheated steam

locomobile with Lentz valve gear, condensation by water injection, multitubular boiler with withdrawable fire-box and flues, and superheater built in in the smoke chamber. It has automatic powdered coal firing, operated by a small motor. The plant is used to drive a 550 volt polyphase generator of 240 kw. output, at 600 r.p.m. In order to avoid long interruptions during boiler cleaning, there has been provided a complete reserve set of fire box and flues. In addition to the measuring apparatus prescribed by law, the boiler is equipped with a superheater thermometer and differential draft gage. The draft is created by a suction fan driven by an electric motor and provided with a governor which regulates the output of the boiler in accordance with the power demand. The engine is governed by a Lentz eccentric governor placed on the crank shaft. The piston rods are provided with Lentz metal packing.

The article describes fully the method of making tests and in several tables reports the results obtained. The following are the most important data:

The steam consumption at rated output was 4.59 kg. (say 10 lb.) per h.p. While the engine is rated at 300 effective h.p., it carried during the test, in a satisfactory manner, a peak load of 429 effective h.p. for 10 to 12 minutes and the steam pressure could still be maintained with powdered coal firing. The mechanical efficiency of the steam engine was found to average over 94 per cent, while the efficiency of the boiler plant and superheater together was established by the first test to be around 80 per cent.

During the preceding two years, the locomobile was in operation on an average of 14 hours per day. The coal consumption established during this continuous operation was found to be, including all losses of firing up and removing clinker, on an average of 0.88 kg. (1.9 lb.) per effective h.p.-hr. in the daytime and 1.06 kg. (2.4 lb.) at night. It must be remembered that the fuel was cheap washed powdered coal of a low heating value which makes these results appear quite favorable. It was found that when the load on the locomobile increased, the coal consumption decreased relatively; on the other hand, when in the period of August to November, 1911, because of lack of water for injection, a very low vacuum was maintained, the coal consumption went up quite noticeably. In this connection a rather curious thing was observed, viz., that the powdered coal, contrary to the case with lump coal, increased in heating value from 5 to 8 per cent with storage. (*Leistungsergebnisse bei der Abnahme und in der Praxis einer 300 PS Heissdampf-Lokomobil-Anlage, Zeits. des Oesterreichischen Ingenieur- und Architekten-Vereines*, vol. 67, no. 38, and 39, pp. 486 and 502, September 17 and 24, 1915, 8 pp., ed).

BOILER INSPECTION ON PRIVATE RAILROADS IN RUSSIA, B. B. Sooshtinski

In 1912, the technical inspection of steam boilers on private railroads was given by the government under the charge of an organization called the Society of Private Railroads for the Inspection of Steam Boilers.

Twenty-five railroads, practically the entire private railroad system of Russia, are in this Society. The latter not only inspects the boiler, but has charge of a large part of the research work connected with the boiler proper, or firing. An extensive program of boiler testing is under consideration. One of the most important elements of success of this Society is that being in the hands of private

companies, it is not deeply involved with red tape (*Nadzor za paravymy kotleni chastykh zheleznykh dorog*, B. B. Sooshtinski, *Bulletin of the Permanent Committee of the Consulting Conferences of the Agents of Various Branches of Service on Russian Railroads* (in Russian), vol. 14, no. 8, p. 872, August 1915, 4 pp., gs).

Strength of Materials and Materials of Construction

BEHAVIOR OF IRON AND STEEL UNDER COMPRESSION IN TESTS,
H. Menden

The article describes a series of tests of considerable interest made in order to determine how the shape of the test piece affects the results of the test. Among other things, the tests are of interest because in them an attempt was made to test iron and steel under compression. In addition to this, there were carried out tests on hardness. The following results have been obtained:

1. As regards the influence of the shape of the test piece in compression tests; the tension at the yield point — σ is not affected by the shape of the test piece within the limits investigated in so far as its magnitude is concerned, but is affected in so far as its visibility is concerned. The elongation — ϵ is increased with the increase of the ratio of h/\sqrt{f} within the limits applied from [(0.5) to 3] and with equal ratio of h/\sqrt{f} they are smaller when the cross section is circular than when the cross section is square.

2. As regards alternating relations, it has been found that the tension at the yield point in compression is equal to that in tension, or $\sigma_{+s} = \sigma_{-s}$. The stress at the yield point σ_s is materially affected by the size of the grain of the material, in such a way that, all other conditions being equal, the stress decreases with an increase in the size of the grain.

The linear relation established by Kürth, for the improvement of the yield point and Brinell hardness by the cold working, viz.: $\sigma_s = 1/c (H - H_0)$ holds for the types of wrought iron and steel used for technical purposes in that the constant $1/c$ remains of the same magnitude for all kinds of wrought iron, while the constant H_0 is a function of the size of grain in that it decreases with the increase of the latter (*Ueber das Verhalten mehrerer Eisen- und Stahlsorten beim Druckversuch*, Herbert Menden, *Stahl und Eisen*, vol. 35, nos. 40 and 41, pp. 1022 and 1052, October 7 and 14, 1915, 11 pp., 10 figs., r.t.).

BINARY ALLOYS OF ALUMINUM, II. Schürmeister

The article describes an interesting series of tests on binary alloys of aluminum.

In so far as good rolling and normal annealing is concerned, zinc is probably the metal which produces by far the greatest improvement in the mechanical properties of aluminum, although the strongest alloys, containing from 25 per cent to 28 per cent of zinc, depart from the very low specific weight. Further, the higher percentages of zinc materially lower the melting point and strongly affect the resistance of the alloy to weathering conditions. The next strongest alloy is that of aluminum with 5 to 6 per cent magnesium, but this alloy has only a low resistance to chemical action. In the third place stand copper alloys, which attain the greatest mechanical strength when the addition of copper is about 3 per cent. It resists atmospheric reactions very well and has still quite a high melting point. From a practical point of view, therefore, this system is

the most available and the most widely used. Next to this come the alloys of aluminum with silicon, nickel, cobalt and iron. Of the rare metals only chromium produces a really material improvement, while manganese, vanadium and molybdenum are also of certain advantage. With all other metals the advantage obtained is so insignificant that it is hardly worth while to add them at all.

The methods of production and machining of the alloys have also been investigated. With proper methods of melting, the difference between the results obtained with the use of graphite or clay crucibles, as well as the various temperatures of pouring, are not substantial. On the other hand, a rapid rolling at high temperatures produces, as a rule, considerable improvement in the elongation obtained, while a cold working which is as thorough as possible, produces a not inconsiderable improvement in tensile strength even after annealing. The resistance of the alloy to chemical actions appears to be somewhat affected by the mechanical and heat treatment of the metal, but it depends essentially on the chemical composition of the alloy. It can be determined with certainty only by thorough tests of long duration made under conditions approximating those of the actual working of the alloy.

As far as casting in molds is concerned, shrinking has also a great importance, since the less is the tendency of the alloy to shrink, the better adapted it is for casting. In general, the author comes to the conclusion that material for casting must be more highly alloyed than that for rolling.

Finally, he found for all aluminum alloys, without exception, that additions of very small amounts, such as tenths and hundredths of one per cent, did not affect either the mechanical or chemical properties of aluminum. This is only natural, since even what is known in the trade as pure aluminum contains usually about 1 per cent or more of "impurities," which are nothing but alloyed elements (*Zur Kenntniss der binären Aluminiumlegierungen*, Hermann Schürmeister, *Stahl und Eisen*, vol. 35, nos. 34 and 39, pp. 873 and 996, August 26 and September 30, 1915, r.).

Miscellaneous

LARGE LAUNDRY FOR HANDLING SHIP WASHING, Wm. Scholz

Description of the large laundry installed by the Hamburg-America line, at Kuhwärder Harbor (leased by that Company).

The necessity for such a laundry was created just before the war by the construction of ships of the *Imperator* type, having a passenger list of more than 4500 and making the trip between Hamburg and New York in from five to six days. During such a trip, both ways, up to 30,000 kg. (say, 65,000 lb.) of wash accumulates, and this has to be taken care of in a very short period of time, between the arrival and departure of the steamer at Hamburg, unless a very large extra stock of linens be kept. To this was added the fact that sending the wash to a private laundry inland involved a lot of troublesome custom formalities. It was decided by the company, therefore, to install a plant of its own which would take care not only of the washing proper, but also the removal of spots and the repair of the linen. That there would be sufficient business for the plant was shown by the fact that it would be called upon to take care of the washing for more than 200 seagoing vessels.

In view of the fact that ships of the *Imperator* type can-

not come in close to the shore in the harbor selected for the site of the laundry, the washing has to be delivered by lighter, which required particular installations to make the handling of it, in and out of the lighters, convenient. For the loading and unloading at shore, a special loading bridge of reinforced concrete, with the exception of the roof, was built. The laundry delivered from the land side is taken in at the east wing of the building and delivered directly to the reception and weighing room. That taken in from the water side is delivered in sacks, weighing 30 to 40 kg. (66 to 88 lb.), to the loading platform in batches of 15 to 20 sacks each, by means of a portable electrically driven loading crane. From the platform, it is delivered inside the building, where it is sorted and weighed.

The washing machinery is not described in great detail; some features, however, are of interest. In order to reduce the number of attendants at the steam mangles, a special device designed by the author of the article, was introduced for handling the washing put in; this device is particularly convenient for mangles handling large numbers of pieces of the same type, such as handkerchiefs, napkins, etc. (In this connection it is mentioned that a steamer of the *Imperator* type brings, after a return trip, something like 40,000 napkins).

The usual output of the laundry for a nine-hour working day, is 8000 to 10,000 kg (17,600 to 22,000 lb.) of fully washed and packed linen. In order to prevent deterioration of large and valuable linen, each piece, which during the sorting process is found to be injured, however slightly, is delivered immediately to a repair shop, equipped at present with 20 electrically driven sewing machines.

The washing machines, centrifugals and steam mangles, are illustrated in the article. The water supply and ventilating systems are briefly described (*Die Grosswascherei der Hamburg-Amerika-Linie in Hamburg-Kuhwärder*, Dr. Wm. Scholz, *Zeits. des Vereines deutscher Ingenieure*, vol. 59, no. 40, p. 815, October 2, 1915, 7 pp., 17 figs., d).

ENGINEERING SOCIETIES

AMERICAN SOCIETY OF CIVIL ENGINEERS

Proceedings, vol. 41, no. 8, October 1915, New York City.
THE AUTOMATIC VOLUMETER, E. G. HOPSON

The paper describes an apparatus intended to gage the flow of fluids by the collection of a proportionate part of the flow or its equivalent, in a small vessel where it can be readily measured at any time. The apparatus is arranged in such a way that the pressure head under which the discharge into the collecting vessel takes place, is at all times equivalent to, or a constant ratio of, the velocity head of the liquid or gas being measured. The name volumeter is somewhat of a misnomer since actually it is the velocity or pressure due to velocity that is its operating force.

The volumeter operates by the velocity head of the fluid which is being measured. Not only is velocity head communicated, but a very small proportion of the actual flow is diverted into the apparatus, though this proportion is so small and the velocity of flow in the diverting pipe so insignificant that there are no appreciable losses of head by friction in the pipe to disturb the basic plan of operation by velocity head. A return pipe from the volumeter to the stream carries away the surplus liquid created by the influent flow. The apparatus may be attached to a pipe with

communication through a Pitot tube, or at submerged orifices, or on a short pipe or box flume of varying cross-section, or in several other ways. The method must only be consistent and be such that the head communicated to the volumeter is a constant factor of the velocity head, which latter is the essential condition.

The most difficult feature of the apparatus to work out was an arrangement whereby the head under which the interior jet operates is kept identical with or a constant factor of the velocity head of the stream. It is necessary for the apparatus to be absolutely automatic and its response to the most minute changes of head to be immediate and of the most delicate sensitiveness. It works in the following manner: The influent entering the upper part of the lower vessel (Fig. 5) creates a pressure at its point of entry equal to the sum of the static and velocity heads of the entering water, the frictional losses in the influent pipe and orifice being negligible, due to their great size and the very low velocities in them. The lighter medium (liquid or gas) con-

FIG. 5 AUTOMATIC VOLUMETER

tained in the lower vessel is thus put under pressure. The upper vessel is connected with the flowing water in such a manner that only the static head is communicated to it. The flow through the small orifice connecting the two vessels, therefore, is for all practical purposes that due to the velocity head or a constant factor of the velocity head only.

The operating details are shown in the figure. The influent enters the lower vessel or container at its upper part through an orifice at A. The pressure communicated is due to the static head of the water being measured plus the velocity head due to the rate of flow. This pressure is communicated to the medium (oil, air or whatever may be used) in the lower vessel and in turn is transmitted through the medium to the lower side of the point of connection with the upper vessel at the orifice C. The water in the effluent pipe is only under the pressure due to the static head of the stream being measured. This pressure is communicated directly through the water in the lower part of the upper vessel down to the upper side of the orifice, C. When there is no velocity, the static head of the stream is communicated to both the upper and lower sides of the orifice, C, and there

is no movement. Whenever there is velocity the corresponding head is at once communicated to the lower side of the orifice C ; the balance of forces is overthrown and a movement is started proportioned to $\sqrt{2g}$ multiplied by the square root of the velocity head less what head is required to overcome the various frictional resistances.

In order to work out this device, the coefficient of flow through very small orifices had to be established and experiments along these lines revealed totally unexpected conditions. It has been necessary to deal here with flow through orifices not exceeding 0.001 to 0.004 ft. in diameter, and apparently with these small openings, the ordinary laws of flow did not apply with the lower heads. Another marked difference between results obtained with these small orifices and with the larger ones is that apparently the former have distinctly greater coefficients under certain heads than the latter.

In addition to experiments with water, runs were made using oil. It was necessary to find an oil having a viscosity which did not change very materially under changes of temperature, such as would be encountered in a water measuring device under working conditions. The oils most nearly approaching these conditions were kerosene, a petroleum product known commercially as white neutral oil, and another petroleum product known as glymol (a thick clear oil, used generally for medicinal and surgical purposes). From experiments, it was found that a very appreciable force was necessary to break the seal of surface tension and induce a flow between the different media through the small orifices required on this apparatus. A study of the curves of coefficients of flow seems to indicate clearly that the reduction of the coefficient with the small orifices under low heads is due largely to some obscure retarding force, such as surface tension, which actually absorbed a portion of the operating or velocity head applies and is, to a considerable extent, a constant in itself.

The principal sources of error in this device are temperature changes affecting the specific gravity of the measuring medium or its bulk. Changes in the air density will also influence the results to a small extent. Some of the causes of error can be avoided or obviated. Others are inherent but tend to a considerable extent to balance and neutralize each other. The apparatus must be set by one who understands the principles of its operation, but its further operation is so simple and automatic that any ditch rider of average intelligence will be able to reset and read it each day or whenever necessary (17 pp., 9 figs., ed.).

TESTS ON THE RECIRCULATION OF WASHED AIR, PROF. G. L. LARSON

Recent investigations have shown that what is known as

bad air is caused by neither depletion of the amount of oxygen present nor excess of carbon dioxide, and symptoms of discomfort in a poorly ventilated place are due mainly to the physical conditions of the air with respect to temperature, humidity and movement, and not to its chemical properties. The present paper describes tests (Wisconsin High School), undertaken in order to ascertain the advisability of installing similar systems in the future buildings of the University of Wisconsin.

The high school building is heated partly by direct radiation and partly by indirect, the system being of the one-pipe direct steam type throughout. Ventilation of the building is provided by a blast fan discharging through ducts on the ceiling of the basement that rise to the rooms to be ventilated and enter the rooms near the ceiling; special systems of ventilation are used for the toilet rooms and the chemical laboratory. The paper describes fully the apparatus and methods used.

Considerable difficulty was experienced in determining the true volume of air entering the rooms. Readings were taken at the duct leading to the gymnasium. First a series of readings were taken at the register and then the register was removed and another set of readings taken, holding the anemometer horizontally in the vertical duct leading to the room. The readings at the register showed an average of 482 ft. per minute and those in the duct showed an average of 810 ft. per minute. The registers are unusually heavy and the net area of the particular size in the gymnasium is only 96 per cent of the area of the vertical duct leading to the room. Therefore the velocity through the register should check very closely with the velocity in the duct, which was, however, very far from being the case. These and other tests showed conclusively that the register deflected air currents inside and gave velocity values which were very much lower than the actual values, so that the readings taken with the anemometer placed against the register are absolutely unreliable.

The author comes to the following general conclusions:

1. The tests show that it is both unnecessary and uneconomical to supply large volumes of air to obtain good ventilation.

2. That 15 cu. ft. of air per student would be ample, providing it enters the room at a fairly high velocity and carries the proper amount of moisture.

3. With humidity ranging from 50 to 70 per cent, the occupants of the rooms are perfectly comfortable at a temperature of 65 deg. or even less.

4. With humidity of about 60 per cent, the air can enter the rooms at a temperature of 60 deg. without creating any discomfort; in fact it seems to give life to the air and aids in the efficiency of ventilation.

5. Carbon dioxide content as high as 20 parts in 10,000 does not have a bad effect upon the ventilation.

6. Ventilation by recirculation is both efficient and economical. At the end of a year's run the teachers are almost unanimous in their praise of the system.

7. With a recirculating system such as this, it requires from 40 to 50 per cent less steam to heat the building, while the fan is in operation, than would be required if the air was drawn from outdoors for the same length of time.

8. Air movement keeps the temperature uniform in various parts of the room and decreases the amount of steam

required for heating. The tests show a minimum saving of about 8 per cent due to this air movement; this would be true whether the system is a recirculating one or otherwise.

9. The air washer absorbs a considerable amount of the carbon dioxide contained in the air passing through it.

10. The air washer is apparently quite efficient as a dust remover but it does not remove bacteria from the air when the washer water is recirculated. The tests show that it actually supplies bacteria to the air under such conditions.

11. In spite of the poor showing of the washer, the air entering the rooms carries no more bacteria than outside air when the relative velocities in which the plates were exposed are taken into account.

Further tests are being planned (41 pp., 11 figs., *de*).

TESTS ON THE SHEARING RESISTANCE OF REINFORCED CONCRETE BEAMS, E. BROWN, H. M. MACKEY and C. M. MORSEN.

The paper describes the results of tests carried out by the authors in connection with the work of a committee of the Society, on concrete and reinforced concrete. The authors state that the formulae derived (for the allowable shearing stress intensities and for computation of stirrups), are admittedly inadequate as a representation of the actual conditions in a beam, but, used in conjunction with experimental data as a means of fixing allowable unit stresses, they may serve as a satisfactory means of estimating the amount and disposition of steel required to reinforce the beams adequately against shears.

Four distinct lines of experimentation were followed, to determine the behavior of beams reinforced with (a) straight rods only on the tension side; (b) combination of straight and bent rods, the latter assisting in carrying the tension due to shearing; (c) straight rods as in (a) assisted by vertical stirrups of different spacing, and (d) a combination of straight and bent rods as in (b) assisted by vertical stirrups of different spacing.

It was found, broadly speaking, that the beams in which some of the main reinforcement is bent up diagonally deflect less than corresponding beams in which all of the main reinforcement is straight. This is a definite action of the diagonal rods. The effects of different stirrup spacings on the deflections are irregular. In many cases, the cracking of beams was checked noticeably by the stirrups and marked increases of ultimate strength resulted by adding stirrups to beams having straight rods only as tension reinforcement. Sometimes a crack would extend directly through the body of a beam so as to enable an observer to see through it, but the stirrups held the two elements of the beam and prevented collapse.

The general effect of stirrups was to raise the ultimate strength very noticeably and when spaced 4 in. apart, shearing failure was eliminated. Shear failure may also be ob-

viated by bending up some of the tension reinforcements in a diagonal direction. The diagonal bending up of rods also greatly increases the ultimate strength and the addition of stirrups to the beams having such diagonal rods, affects the manner of failure rather than the load at failure.

The tests were carried out mainly with reference to the clause of the specification adopted by the Canadian Society of Civil Engineers (clause 28) (20 pp., 2 figs., *c*).

COLLEGE OF ENGINEERING, KYOTO IMPERIAL UNIVERSITY

Memoirs, vol. 1, no. 4, August 1915, Kyoto, Japan.

ON LEONARD CONTROL APPLIED TO MINE HOISTS, Risaburō Torikai.

The paper considers the load diagram, the gradual rating and the theoretical durations of acceleration and retardation of a direct current mine hoist motor controlled by the Leonard system, without entering upon discussion of the equalizing apparatus. It is to a certain extent an extension of the paper by Wilfred Sykes on large electric hoist plants in the Proceedings of the American Institute of Electrical Engineers, Vol. 29, Part I, 1910.

The paper gives the general equations of the resisting moment of hoist as well as equations from which may be found the economical relation between acceleration and retardation. An equation is given from which may be determined, though with some difficulty, the capacity of the hoist motor, taking iron losses into account. The subject is treated mathematically. (33 pp., 3 figs., *m*).

TESTS OF STANDARD AND CLASP BRAKE RIGGING FOR PASSENGER TRAIN SERVICE, E. F. LICKEY

The paper is mainly an extract from a report submitted to the officials of the Lake Shore and Michigan Southern Railway by the engineers who carried out these tests.

Several years ago, the L. S. and M. S. Railway had, in common with other roads, a great deal of trouble with skid flat wheels, caused by the heavy braking pressures necessary on account of the increased weight of equipment and aided by the cold winter weather and frosty rails. The clasp type of brake rigging was proposed as a means of overcoming the trouble and in order to determine what advantage, if any, the clasp brake arrangement possessed over the standard foundation brake rigging, a series of tests were made near Toledo, O., by a group of engineers representing the Westinghouse Air Brake Company and the L. S. and M. S. Ry. The track was equipped with a chronograph and the necessary circuit breakers. The necessary speeds were obtained by running the train back several miles distance, depending upon the speed desired and then making the run toward the tripping point; at the trip, the engine was cut loose from the train and the latter was braked by making the desired brake pipe reduction. The speed was judged from a Boyer recorder on the engine and by experience. Brake cylinder pressures were recorded by indicators attached to them.

Under like conditions of standing piston travel and brake pipe pressure, the clasp brake ears stopped slightly shorter than the standard brake ears. It was found that with approximately 150 per cent nominal emergency braking power on the clasp brake ears and 170 per cent nominal emergency braking power on the standard braking ears, the difference in running piston travel with the two equipments will be such that the actual percentage of braking power realized will produce practically the same stop with each type of rigging.

The stops with the three clasp brake ears vary through a considerably narrower range than that for the three standard brake ears with the same percentage of braking power, which indicates that the clasp brake insures a greater uniformity of brake action. A single ear emergency test made to find out if there was any greater variation in rates of retardation on individual ears with the standard brake than there was on ears with the clasp brake, indicated that on the basis of the same amount of braking power, the individual ears vary but little and approximately the same amount for both types of rigging.

Comparative tests of standard brake ears with and without emergency reservoirs have shown that there was an average increase of about 166 ft. in the length of stop when the emergency reservoirs were cut out, which is, however, only the difference between the best and the poorest stops by the standard brake ears with the emergency reservoirs cut in. Practically the same relation between the emergency stops with emergency reservoirs in and out was found to exist with the clasp brake ears as with the standard brake ears.

With the standard brake rigging, it was observed that the high pressure exerted by the single shoe on one side of the wheel, tilted the axle bearing brasses sufficiently to lift one side of the brass a considerable distance away from the journal, so that a wide space was opened for waste to be caught between the brass and the journal when the brake was released; these effects were noted in service applications of the brake as well as in emergency applications. With the clasp brake arrangement, however, nothing of this kind was noted.

No record of the amount of brake shoe wear, by weighing of the shoes, was taken. It was noted, however, that the temperature of both wheels and brake shoes with clasp brake ears was uniformly much lower than with the standard brake rigging. On the whole, the conclusion was arrived at that the clasp type of brake was the proper design for use on heavy passenger equipment (7 pp., 2 figs., c).

SOCIETY OF CHEMICAL INDUSTRY

Journal, vol. 34, no. 19, October 15, 1915, London.

VULCANIZATION EXPERIMENTS ON PLANTATION PARA RUBBER.

THE CAUSE OF VARIABILITY, B. J. Eaton and J. Grantham.

The writers call attention to the controversial statements made during the last two or three years, concerning variability in plantation Para rubber. While some manufacturers claimed that the variation is considerable, even in the case of "First latex" rubber when compared with fine hard Para, or first grade of wild Para rubber, leading rubber technologists maintain that the best grades of plantation Para rubber, especially sheet, are superior to fine hard Para. The writers, on the basis of an extensive series of experi-

ments made at the testing laboratories of the Department of Agriculture, Federated Malay States, claim that both opinions may be taken as correct and are not necessarily contradictory.

They come to the following conclusions:

(1) Considerable variation occurs in plantation Para rubbers, even in the case of "First latex," both among rubbers from the same estate and from different estates.

(2) This variation is connected principally with the behavior of the rubber on vulcanization, i. e., its rate of cure and not in respect to its strength, elasticity, and general mechanical properties, especially in the case of properly prepared "first latex" samples.

(3) If the rate of cure be known or ascertained under specific conditions, vulcanized rubber having similar chemical properties can be made from all good samples of "first latex" rubbers.

(4) A difference in mechanical properties does exist, even among so-called first quality rubbers, but these differences are greater between high and low grade plantation rubbers; some rubbers never attain the maximum mechanical properties reached by others, whatever period of cure is adapted. These differences, in the case of the "first latex" rubbers, however, are not so important to the manufacturer as the differences in rate of cure, and are not of the same order. Indeed, the remarkable uniformity in type of curve points to the fact that the variation of mechanical properties in our samples, at any rate, is of an accidental nature, for at points below the breaking point the mechanical properties are the same.

(5) The rate of cure is due to the presence of some non-caoutchouc substance in the latex, possibly protein or some other organic constituent, or to some degradation product derived from these substances, which acts as a catalyst, and accelerates the rate of cure.

(6) This substance may be already present in the latex, and its amount in the raw rubber determined by the mode of preparation and coagulation, or it may be subsequently formed in the latex by decomposition and taken up by the rubber in variable quantity, according to mode of preparation, or, alternatively, it may be formed in the coagulum in variable quantity, depending on the amount of serum (or moisture) left in the coagulum or the presence of preservatives which hinder or prevent its formation. The alternative theories await investigation.

(7) Smoking, removal of excessive serum in the washing and machining processes, and preservatives are among the artificial factors which either hinder the formation of this substance, or, if it already exists in the prepared rubber, partially destroy it.

(8) The catalytic substance is probably not affected greatly by the heat, since in the process of mixing and vulcanization, the rubber is subjected to relatively high temperature. Whether heat destroys it or prevents its formation in the latex or freshly coagulated rubber awaits investigation.

(9) The rate of cure of a rubber under specific conditions is not indicated in any way by the apparent mechanical or any other apparent properties of the raw material, hence the worthlessness of the present methods of valuation of rubber.

(10) *Ceteris paribus*, a manufacturer probably prefers a rapidly curing rubber, since it represents economy in heat, labor, and time costs, and secondly, a rubber which cures

rapidly is said to have better keeping qualities after vulcanization.

(11) Uniformity between "first latex" rubbers from different estates will probably be very difficult of attainment with present methods, owing to the number of factors involved, but should not be so difficult among such rubbers from the same estates.

(12) Two alternatives are suggested: (a) The issue of certificates giving correct rate of cure and mechanical properties at this cure; (b) The attainment of more uniformity by the method suggested in this paper and elsewhere, in which rubber from latex collected during a series of days forms part of one ball or block, which may be described as the method of averages (11 pp., 5 figs., *cpd*).

UNIVERSITY OF ILLINOIS

Bulletin, vol. 12, no. 47, July 26, 1915, Urbana, Ill.

INFLUENCE OF TEMPERATURE ON THE STRENGTH OF CONCRETE. A. B. McDaniel

A

FIG. 6. A, RELATION OF STRENGTH TO TEMPERATURE FOR DIFFERENT AGES; B, PERCENTAGES OF STRENGTH FOR DIFFERENT TEMPERATURES

The purpose of the bulletin is to furnish information based on experiments to determine the influence of temperature on the attainment of strength in concrete. The author comes to the following general conclusions:

First. Under uniform temperature conditions, there was an increase of strength with age within the limits of the tests. For any temperature the rate of increase decreases with the age of the specimen; and this rate of increase is less correspondingly at the lower temperature conditions. For the specimens tested, under normal hardening temperature conditions of from 60 to 70 deg. fahr., the compressive strength of the concrete subjected to a uniform temperature at the ages of 7, 14 and 21 days may be taken as approximately 50 per cent, 75 per cent and 90 per cent of the strength at twenty-eight days, respectively. For lower temperatures the percentage values are less, and for higher

temperatures the percentages are higher. The relation between the percentage values at the age of 7, 14, 21 and 28 days is nearly the same for temperature conditions from 30 deg. to 70 deg. fahr. However, the values for the lower temperatures should be used with caution.

Second. Concrete which is maintained at a temperature of 60 deg. to 70 deg. fahr. will at the age of one week have practically double the strength of the same material which is kept at a temperature of 32 deg. to 40 deg. fahr.

Third. Figs 6A and B may be used to determine the representative strength of concrete similar to that used in these tests, for various temperature conditions and for ages up to 28 days. These diagrams may be used with a fair degree of approximation to ascertain the relative strengths which concrete of ordinary practice may be expected to attain at the different temperatures. It should be noted that generally in this investigation the specimens were stored under temperatures which were nearly uniform during the whole storage period. The tests summarized in Fig. A and B cover a

B

wide range of temperature conditions, the average temperature varying from 20.4 deg. fahr. to 90.6 deg. fahr., and are fairly consistent; and hence it is believed these values are sufficiently accurate to furnish suggestive information which may be useful in determining the time when forms may be removed and loads applied. The results accord with the well-known effect of freezing and thawing upon green concrete (24 pp., 15 figs., *c*).

CLASSIFICATION OF ARTICLES

The various articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of exceptional merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society.

MEETINGS

CINCINNATI, OCTOBER 21

The regular October meeting of the Cincinnati Section of the American Society of Mechanical Engineers was held as a joint meeting with the Engineers' Club of Cincinnati, on October 21. The speaker was O. Monnett, of the American Radiator Company, formerly Associate Editor of *Power*, and Chief Smoke Inspector of the city of Chicago. His remarks were based upon a very fine collection of lantern slides which had been accumulated during his efforts to eliminate smoke in Chicago. Mr. Monnett began by describing and showing the dutch oven construction for hand-fired furnaces under boilers. He reviewed the experiences with this form of setting before it was abandoned, and showed that its failure to burn coal smokelessly, or nearly smokelessly, was due to a rapid distillation of the volatile matter in the coal from the intense heat of the top arch. The speaker then took up in detail the various furnaces for hand firing that were developed in Chicago until the latest form of double arch bridge wall furnace was devised. The speaker mentioned the fact that this furnace had been quite successful in Chicago, and that it had been adopted by the city of Cincinnati for burning of high volatile fuels.

Mr. Monnett said that the chief factors in smokeless combustion are temperature, mixture, time, and oxygen. In other words, that there must be present sufficient oxygen to burn volatile hydrocarbons, that there must be an intimate mixture of the oxygen and hydrocarbons, that there must be sufficient time for the burning before the comparatively cool surfaces of the boiler itself are touched by the gases.

After a very thorough discussion of the principles underlying the design of hand-fired furnaces for high volatile coals, Mr. Monnett showed slides illustrating the application of the most general principles to various forms of mechanical stokers. He stated that the chain grate stoker was very satisfactory for the non-caking coals that are generally used in Chicago, while experience has shown that the non-caking coals, coming to the Cincinnati market from West Virginia, Pennsylvania, Kentucky, and other states, were not readily burned with high efficiency on the chain grate. He also referred to a careful study of heatings of various boilers, the measurements having been taken from hundreds of tests.

The presentation of the paper was followed by a vigorous discussion. Among those taking part in the discussion were A. G. Hall, J. J. Nels, J. T. Faig, Members Am. Soc. M. E., and the Chief Smoke Inspector of the city of Cincinnati. There were about 100 members and guests present.

PHILADELPHIA, OCTOBER 26

The first regular meeting for the coming season of the Philadelphia section of The American Society of Mechanical Engineers was held at the Engineers' Club on Tuesday evening, October 26. The paper was by J. A. Steinmetz, Mem. Am. Soc. M. E., and President of the Pennsylvania Aero Club. The paper reviewed in an interesting manner the development of the aeroplane in France and Germany and finally described, with lantern slide illustrations, methods of aeronautical warfare. The speaker said that as well might a blind man go forth to battle as an army without its aerial eyes. The old days of cavalry reconnaissance and of surprise turning movements of the flank are impossible be-

cause of the all-seeing eyes of the flying man high in the cloud land.

The French and German aeroplane fleets of today were built largely by public subscription. In February 1912 the potentiality of the air service was demonstrated in France, but the French government failed to allow the appropriations necessary for its development. But in every part of France the people, rich and poor, old and young, united their efforts with the press and various organizations to give France a large aerial fleet. A huge public subscription was raised which gave France 208 aeroplanes, 62 landing stations for aeroplanes and 75 trained aviators. The interest created was tremendous and the government took up the matter until in 1914 the army possessed 1200 aeroplanes and 28 dirigibles.

Germany's aeroplane fleet was built almost entirely by public subscriptions, started by the Aerial League of Germany in 1912. As in France, this popular movement led to action by the government and the Reichstag provided a plan for an expenditure of 35 million dollars for military aeronautics during the five years following. In 1914 the inducements offered by the Aerial League led to the breaking by German aviators of all the world's flying records. For instance, continuous flights of nearly 22 hours were achieved, a distance of 1336 miles was covered in one day and an altitude of 21,654 feet was reached.

The author held that just as the people in every part of France and Germany had united their efforts for the advance of aviation, so here in America the same could be accomplished, for "surely we Americans with our greater resources can do even better."

ST. LOUIS, OCTOBER 26

Under the auspices of the St. Louis Section of the Am. Soc. M. E., the Engineers' Club, together with the associated local societies including the American Society of Civil Engineers, the American Institute of Electrical Engineers, and the American Society of Engineering Contractors, held a meeting in honor of the President and guest of the Am. Soc. M. E., Dr. John A. Brashear, on October 26 and 27. Dr. Brashear was met at the station by the Executive Committee of the Am. Soc. M. E. and William Haren, a personal friend of Dr. Brashear's, and owner of the first Brashear lens ever brought to St. Louis. After a visit through the St. Louis park system and to the Art Museum, Dr. Brashear was escorted to the City Club for lunch after which he gave a short address entitled, "Reminiscences." Dr. Brashear's talk touched on some of the most prominent facts that astronomical work has brought forth in the last century, and was interspersed with many interesting personal anecdotes. Dr. Brashear was personally a stranger to most of the St. Louis Section, and had been heralded as a maker of scientific apparatus and an astronomer, and the audience was delighted to find him also one of the most human of human beings.

The afternoon was spent in showing Dr. Brashear parts of the old section of St. Louis including the famous Shaw's Garden. At 6:30 an informal dinner was served at the Washington Hotel, at the close of which Dr. Brashear spoke a few words which left the audience with a feeling that in studying the stars and their distances into the millions of light years he was also studying divinity and humanity in the largest way. Following his remarks, Prof. Nipher gave a

short talk on the infinitely small divisions of the atom at which he was working which signified that he is studying the same vast subject as Dr. Brashear at the opposite extremity of dimension.

At eight o'clock, 1200 engineers of St. Louis with their guests assembled in the Soldan High School and listened to Dr. Brashear's illustrated story of the great telescopes of the world and the discoveries made by their use.

The next day Dr. Brashear addressed the students at Washington University at chapel and at a luncheon tendered him by the University.

PROVIDENCE, OCTOBER 27

A meeting of the Providence Section of Mechanical Engineers was held in Brown University on October 27. The special feature of the meeting was an address, fully illustrated, by Arthur W. Dow, Mechanical Engineer of the Dow & Smith Company of New York, on the subject of Modern Highway Pavements. Invitations to the meeting were sent to city and state authorities both in Rhode Island and southern Massachusetts, and there were a great many representatives from these authorities present.

BUFFALO, NOVEMBER 3

At a meeting of the Engineering Society of Buffalo, held on November 3, Mr. Hunt, Chief Engineer of the Packard Motor Car Company, gave a paper on the Multiplicity of Cylinders. He dwelt on the engineering relations of balance, and inertia forces, on the four, six, eight, and twelve cylinder gasoline engines. He came to the conclusion that the last is the most satisfactory. There were nearly 400 members and guests present.

NEW YORK, NOVEMBER 9

A meeting of the New York local section, at which John J. Swan, Mem. Am. Soc. M. E., presided, was held on November 9.

Under the title, An Investigation of Gas Producer Power Plants in New York City and Vicinity, Charles Meigs Ripley, in the paper of the evening, reported the results of a census of opinions obtained from owners of private gas plants in this city regarding repairs, labor, depreciation, satisfaction with their plants or otherwise, and future installations.

The author had tabulated these data, as well as sizes, costs, loads, fuels, attendance, and ages of the plants, and presented it in the form of charts, the plants represented in which he discussed in considerable detail.

The paper was discussed by John H. Norris, Mem. Am. Soc. M. E., H. G. H. Tarr, E. Rathbun, Mem. Am. Soc. M. E., and Wm. T. Price, Mem. Am. Soc. M. E. Both paper and discussion are published in this issue of The Journal.

MILWAUKEE, NOVEMBER 10

An interesting meeting of the Milwaukee Section was held on November 10, at which about 130 members and guests were present. At the meeting, Robert Cramer, Mem. Am. Soc. M. E., gave a paper on High Pressure Boiler Design:

High steam pressures at the present time are an established fact. A steam turbine of 20,000 kw. capacity to work under 600 lb. steam pressure is in the course of construction and is to be installed, together with boilers capable of giving this pressure, in a large power house.

The theoretical comparisons referring to the advantages of high steam pressure form the subject of a paper to be delivered by the author at the Annual Meeting of the Am. Soc. M. E. in New York City on December 8. This matter is therefore referred to very briefly here.

In the gradual development of practice in steam engineering the limit of temperature has been apparently reached with 600 deg. Fahr. The limit of pressure, however, has not been reached with the current practice of slightly over 200 lb.

The justification for the introduction of high steam pressures lies in the gain in fuel economy while the practical difficulties lie in the structural parts of the steam boiler. It is necessary to retain the essential characteristics of circulation such as are found in water tube boilers at the present time, because these characteristics make it possible to handle the regulation of the fire and the feed independent of each other. The question whether circulation can be obtained in a boiler constructed entirely out of tubes is therefore of prime importance.

The characteristics of the water tube boiler, provided with steam drum and water level, are compared with that of another type of boiler made of tubes only. The point is brought out that with the latter type of boiler, steady circulation is obtained.

In realizing this point in practice, the boiler is built up of a number of so-called *Sections*, each section consisting of two headers which are connected by a number of horizontal tubes. The headers are connected to a common steam drum and a common water drum. The difficulties which arise from the operation of a number of sections in groups are illustrated, and means for meeting them are described.

The advantages of this sectional construction are also apparent in practical operation. It is possible to remove any section at any time for the purpose of cleaning and repairing. This operation can be done in day-light under conditions of perfect accessibility. After removal of the sections the interior of the furnace is easily accessible for inspection and repair.

If steam pressures of 600 lb. are employed the water in the boiler is approximately 100 deg. hotter than it is if the boiler carries only 200 lb. pressure. Other conditions being equal this will cause the flue gases to leave the heating surface of the boiler at a temperature of approximately 100 deg. higher than what is the usual practice. To offset the consequent loss in efficiency, without a large increase of heating surface, it is necessary to install a certain amount of economizer surface. The amount of economizer surface sufficient to offset this loss in efficiency is easily provided in the tubes which connect the feed drums to each individual section. These tubes of the boiler structure form a natural part of the boiler construction.

Under pressures as high as 600 lb. per sq. in., difficulties are encountered with glass water level indicators. A new construction of steel water level indicator is shown. The changes in the water, in this apparatus, influences the temperature of a mass of mercury, the expansion of which indicates the change.

In conclusion, it is pointed out that in judging any attempt to realize the advantages of high steam pressure it becomes necessary to balance the gain in fuel consumption against any increase in cost of the necessary apparatus. It is claimed that the boiler construction as shown, even under pressures

as high as 700 lb. per sq. in., does not involve a cost higher than that of present types of boilers for pressures not higher than 200 lb. per sq. in. It is therefore expected that the full theoretical benefit of high steam pressures can be realized in practice.

LOS ANGELES, NOVEMBER 13.

The Los Angeles Section of The American Society of Mechanical Engineers held a very successful meeting on November 13. During the afternoon and evening the members and their guests visited the laboratory of the Mt. Wilson Solar Observatory and inspected the new 100 in. mirror for the reflecting telescope now being erected on Mt. Wilson, as well as the grating ruling machine, and the mechanical and physical equipment of the laboratory. Dr. Hale spoke briefly in regard to the purpose and aims of the Observatory illustrating his talk with actual photographs and slides.

Dinner was served at the Hotel Maryland, forty-three members and invited guests being present. After the dinner, F. G. Pease, Mem. Am. Soc. M. E. and of the Observatory staff gave a talk that was profusely illustrated with lantern slides illustrating the mechanical equipment of the laboratory and its work. The laboratory and the observatory equipment are unique in that they are designed and built in the observatory shops, the equipment being designed from the standpoint of the mechanical engineer rather than the standpoint of the instrument maker.

BUFFALO, NOVEMBER 17

The Engineering Society of Buffalo held a successful meeting on November 17 at the J. P. Devine Company's plant in Buffalo, at which John Calder, President of the Metals Coating Company of America, addressed the Society on the Schoop Process of Spraying Metals. The lecture was accompanied by a very interesting demonstration of a process new to America, the coating of wood, paper, iron, steel and other substances with metals.

The importance of the process which was brought to this country by Mr. Calder from Switzerland, is, as regards steel-and-iron construction, the arrest of corrosion and rust. Mr. Calder explained that that tuberculosis which iron and steel suffers from, has been arrested to some extent temporarily by paints, enamels and their substitutes.

It is important in the preparation of food products that the vessels used do not corrode. It is important also in construction that the irons and steels do not rust; that the other metals used resist decay. Each material can be coated, to any practicable thickness desired, with electro-positive, non-corroding metals.

Bronze wires, brass wires, aluminum, lead and copper wires were melted a tiny drop at a time during the demonstration. These drops of melted metal were thrust through a spraying brush with oxygen at the rate of 3,500 ft. a second. The metal thus treated is, theoretically, blown into its component molecules. These are thrust into the fiber, grain or texture of the object and, as the spraying continues, a hard surface or coat of the metal is deposited. The coated surface may be polished if desired.

The coating process had developed a new business in novelties. Various articles, apparently metal, are now being marketed at low prices which, the lecturer explained, are really wood coated with bronze or other metals. For the engineers the chief interest was, of course, the demonstration

of the claimed effective prevention of decay, which threatens all structural metals. The paper called forth considerable discussion regarding the possibilities of this process. Nearly 250 members were present.

NEW HAVEN, NOVEMBER 17

The splendidly managed fall meeting of the New Haven section was held in the Mason Laboratory of Sheffield Scientific School on Wednesday, November 17. Afternoon and evening sessions were held and about one hundred and fifty were in attendance.

Dr. L. P. Breckenridge, Mem. Am. Soc. M. E., presided in the afternoon while Charles L. Warner, Mem. Am. Soc. M. E. presented a paper on the ingenious wire-forming machines made by the Baird Machine Company, of which he is president. Albert A. Dowd, consulting engineer of New York City and on the staff of Machinery, gave most valuable information and shop hints on work-holding devices for lathes, boring mills and planers.

It is papers like the latter which return to the member of the Society many times the amount of a member's dues. The other papers were highly interesting and instructive and presented by authorities in their respective specialties, but Mr. Dowd was able to give suggestions which would save shops hundreds of dollars.

At the completion of the afternoon session, a dinner was served in the inspiring Yale Dining Club Hall.

Prof. J. W. Roe, Mem. Am. Soc. M. E., presided in the evening, when Calvin W. Rice, Secretary Am. Soc. M. E., spoke for a few moments. He stated that it would be taken for granted that the Society was especially successful so he wanted to emphasize the success of all the societies and the profession generally. Coöperation of the societies in the International and Panama Congresses, in legislative matters, with the United States in the Naval Advisory Board and in the as yet unannounced work with the War Department, indicated the more leading part the engineers are taking in society generally. Coöperation between the engineering societies in local affairs was urged and a joint meeting for the 1916 spring meeting in New Haven suggested.

Ralph E. Flanders, Mem. Am. Soc. M. E., followed with a splendid presentation of the subject of gear cutting machinery. Geo. O. Gridley, Mem. Am. Soc. M. E., who has contributed perhaps more than anyone to the advancement of the art of automatic screw machines, closed the session.

MINNESOTA, NOVEMBER 18

The November meeting of the Minnesota Section of the Am. Soc. M. E. was held at the University of Minnesota on November 18. At the afternoon session three papers were read, one by Ray Mayhew, Mem. Am. Soc. M. E., and Mechanical Engineer of the Minneapolis Steel & Machinery Company, on Stationary Gas Engines, one by S. C. Shipley, Mem. Am. Soc. M. E., and Assistant Professor of Machine Construction of the University of Minnesota, on Gas Engine Ignition, and one by W. G. Clark, Engineer for the Wilcox-Bennett Carburetor Company of Minneapolis, on Carburetion in Gas Tractor Work. Following this a dinner was served in the Minnesota Union.

At the evening session two papers were presented, one by E. Russell Greer, Mechanical Engineer for the Lion Tractor Company, on Gas Tractor Engines, and one by S. L. Hoyt, Assistant Professor of Metallography at the University of

Minnesota, on the Use of Special Steel in Gas Tractors and Automobile Construction. There was a total attendance of 145 members, visitors and students.

PROVIDENCE-BOSTON, NOVEMBER 18

A very successful joint meeting of the Providence Association of Mechanical Engineers and the Boston Section of the Am. Soc. M. E. was held in Providence on November 18. In the afternoon a choice of excursions was given to the Gorham Manufacturing Company, the largest firm of silversmiths in America; the General Fire Extinguisher Company, the largest fire prevention company in the world, and the Brown & Sharpe Manufacturing Company, so well known for the high grade tools and machines manufactured. The last part of the afternoon the members and guests were cordially received and entertained by the Brown University authorities in the engineering laboratories. Following this, a banquet was served at 6:15 at the Hotel Narragansett. The meeting was presided over by A. H. Amman of the Providence Association, and he introduced William Howard Paine as toastmaster. The visiting members to the city were cordially welcomed by His Honor Mayor Joseph H. Gainer. Following this, Dr. W. H. P. Faunce, President of Brown University, spoke of the engineers, not as malefactors but as factors of great wealth, and said that to judge by the attendance of over 500, engineering appears to be as popular as politics. He mentioned the need of applied science and the necessity of harnessing thinking with practical work to bring results and value to the world at large.

Prof. Charles E. Munroe, Dean of George Washington University, gave a very interesting and instructive discussion of the subject of Explosives and the Engineer, pointing out the various characteristics in different kinds of explosives, giving their history and important results achieved. To illustrate the enormous amount of explosives used he mentioned that nearly 9,000,000 lb. per year had been used at Panama, and that on October 10, 1885, Hell Gate was blown up by a charge of 285,000 lb. of dynamite and rackerock, this being the largest charge ever set off at once, and blowing up an area extending over nine acres.

Morris L. Cooke, Director of Public Works at Philadelphia, spoke of his experiences as an engineer in public office. He stated that public business should be modeled on private business, that city governments as a rule have little control over, or knowledge of public service corporations, and that the greatest accomplishment of a municipal engineer or contractor of public works can be in connection with public utilities. He stated that people did not object to authorizing the expenditure of money, provided they got objective evidence that they were to receive one dollar's value for one dollar expended.

Next followed an exposition of the development of an international telephone system by M. C. Rorty, Engineer of the American Telephone and Telegraph Company, illustrated by moving pictures, and later by actual conversation with San Francisco, each one present being provided with an individual receiver. This feature was carried out through the courtesy of the management of the American Telephone and Telegraph Company.

The joint meeting was a very successful one and there were nearly 600 members present at the banquet. The papers which were presented appear in the technical section of this issue of The Journal.

PHILADELPHIA, NOVEMBER 23.

A meeting of the Philadelphia local section was held on November 23, 1915, at which W. P. Barba of the Midvale Steel Company presented a paper on Industrial Safety and Principles of Management. This paper is printed in full in another part of this issue.

NECROLOGY

ROBERT A. MCKEE

Robert A. McKee was born on September 12, 1873, in Towanda, Pa. He graduated from Lehigh University with the degree of M. E., in 1895. For a short time after graduation he was employed by the Brooks Locomotive Works of Dunkirk, N. Y., as draughtsman and designer. He then went to Cornell University to take a course in Marine Engineering, receiving in 1897 the degree of M. M. E. Returning to the Brooks Locomotive Works, he worked in the capacity of designer. In 1899 he became connected with the Baldwin Locomotive Works, remaining there until 1900, when he took a position with the Holly Manufacturing Company of Lockport, N. Y. Here he started as a tracer and was rapidly advanced to the position of leading designer. After fifteen months he left this position to enter the employ of the Westinghouse Machine Company at East Pittsburgh, Pa. In 1904 he was engaged by the Allis-Chalmers Company to take charge of the development and construction of steam turbines. It was due to his efforts more than those of any other individual that the steam turbine department developed along lines which have proved to be based on correct fundamentals. His advice on steam problems was sought by leading engineers and his reputation as a steam turbine engineer extended to foreign countries. Mr. McKee was a member of the American Institute of Electrical Engineers. He died in New York on September 5, 1915.

RAYMOND EARL CRANSTON

Raymond Earl Cranston was born in Providence, R. I., on November 25, 1883. He was educated in the Providence schools, spent one year in Brown University, and graduated with honor in 1906 from Massachusetts Institute of Technology with the degree of B. S. He then entered the employ of the Manufacturers' Mutual Fire Insurance Company of Boston. Later he was sent to the Providence office and became associated with John R. Freeman in his private engineering work. In 1912 he went to California with Mr. Freeman as assistant on the Hetch-Hetchy water supply for San Francisco. Soon after he became assistant engineer for the insurance company.

Mr. Cranston was a member of the Providence Society of Mechanical Engineers. He died at his home in Providence on June 25, 1915.

JOHN LOYD

John Lloyd was born in Newton, Mass., on May 1, 1837. He received his education in the public schools, and learned the machinist and engineering trades. At the outbreak of the Civil War he entered the United States Navy. He was commissioned as acting third assistant engineer and was later promoted to first assistant engineer. On May 7, 1867, he was ordered to the Portsmouth Navy Yard as assistant engineer, and was granted an honorable discharge Decem-

ber 27 of the same year. Shortly afterward he started into business in New York City in the manufacture of machinery, knives and dies under the firm of McLoughlin, Grover and Leyd. On the death of his partners he continued the business under the name of the John Loyd Company.

Mr. Loyd was a member of the Military Order of the Loyal Legion, the Navy League, the Society of Naval Architects and Marine Engineers, the American Society of Naval Engineers and the Metropolitan Museum of Art. He died at his home in Brooklyn on October 5, 1915.

HORACE WYMAN

Horace Wyman, whose death occurred on May 8, at his country home in Princeton, was born in Woburn, Mass., on November 27, 1827. He was educated in the academies at Woburn and Francestown, N. H., and began his business career in 1846, when he became a machinist in the works of the Ameskeag Manufacturing Company at Manchester, N. H. He was later employed by the Lowell Machine Company and by the Hinkley Locomotive Works at Boston, and served as draughtsman with the Holyoke Water Power Company.

About 1860 Mr. Wyman became associated with George Crompton of Worcester. He was made superintendent and manager of the Crompton Loom Works, holding that position until the consolidation of the business under its present name of Crompton & Knowles Loom Works. Mr. Wyman was then made vice-president and consulting mechanical engineer of the company, retaining that position until his death.

All through his many years of service with the Crompton and the Crompton & Knowles Loom Works he applied himself to invention of looms and textile machinery until he had practically perfected looms as they are now used. His inventions made it possible for woolen, gingham and silk fabrics to be woven in more than one color and in larger pieces than before. Through the processes developed by him, rugs and carpets can now be manufactured in size large enough to cover the floor of a room. Textile mills all over the country are using every day machines invented by Mr. Wyman. He is regarded as having done more for the loom industry than any other man in Worcester and possibly in the country. His inventions were the largest single factor in the success of the Crompton & Knowles Loom Works.

He was a member of the Worcester County Mechanics' Association and the Worcester Society of Antiquity.

WILLIAM WATSON

William Watson was born in Nantucket, Mass., on January 19, 1834, and died at his home in Boston on September 30, 1915. He graduated from Harvard in 1857, and took the Boyden prize for mathematics in which he excelled in his work in engineering. The same year he became an instructor at Harvard in differential and integral calculus. Later he took a course of special study at the École Nationale des Ponts et Chaussées in Paris. On returning to this country he became university lecturer at Harvard. While in Europe, Prof. Watson collected from 1860 to 1863 information on technical education which was made the basis of a plan of organization in 1864 of the Massachusetts Institute of Technology, where from 1865 until 1873 he was professor of mechanical engineering and descriptive geometry.

Professor Watson was United States Commissioner in 1873 to the Vienna Exposition and he served as a member of the International Jury of the Paris Exposition in 1878.

He had been honorary president of the Paris Congress of Architects and vice-president of the engineering section of the French Association for the Advancement of Science, serving several terms, and vice-president of the International Congress of Construction in 1889.

He was a member of the French National Academy at Cherbourg, Société des Ingénieurs Civils de France and the American Society of Civil Engineers. He was a fellow of the American Academy of Arts and Sciences, member of the American Association for the Advancement of Science, the Colonial Society of Massachusetts and the Mathematical Club. He was the author of many notable works on technical education and science, engineering, architecture and other subjects.

WALTER SEAVER BALL

Walter Seaver Ball was born March 17, 1867, at Upton, Mass. He was educated in the Upton schools and graduated from Worcester Polytechnic Institute with the degree of S. B. in 1889. He was associated for a short time with the Dean Steam Pump Company at Holyoke, and in 1894 he became connected with the McKay Metallic Fastening Association as assistant to the superintendent. He then became assistant superintendent with the United Shoe Machinery Company and later moved from Winchester to Beverly with this company. For twenty-three years Mr. Ball held a position of great responsibility with the allied companies making this great industry. He died on September 11, at the Beverly Hospital.

TEILE HENRY MÜLLER

Teile Henry Müller was born January 18, 1841, at Grossensiel-Oldenburg, Germany, and was educated at the Polytechnic School of Hannover, completing the course in mechanical engineering in 1862. He then entered the service of the North German Lloyd Steamship Line as ship engineer. In 1865 he came to New York and was engaged first as machinist and later as draughtsman by the Root Steam Engine Company. He left this firm in 1866 to accept a position as superintendent engineer with the Convex Weaving Company, designing and building their mill and machinery. He then took the position of superintendent with the Eagle Pencil Company to redesign their machinery and revise the processes of manufacturing pens, pencils and other articles. In 1877 he entered the employment of S. S. Hepworth & Company, sugar engineers, as superintendent. He designed the California Sugar Refinery in San Francisco for Claus Spreckels and the Belchers Refinery in St. Louis, and built a large part of the machinery for these factories. Later he designed and built the Spreckels Refinery in Philadelphia, the National Sugar Refinery in Yonkers, and designed and partly built the Camden Sugar Refinery. In 1900 he was engaged by the Federal Sugar Refining Company as constructing engineer and built their works in Yonkers in 1914. Mr. Müller continued in this position until the time of his death, which occurred on September 21, 1915.

WALTER K. MITCHELL

Walter K. Mitchell was born October 13, 1866, in Glasgow, Scotland, and came to this country very early in life. He was educated in the schools of Pittsburgh and served an apprenticeship as machinist with the Jones & Laughlin Steel Company. From 1889 to 1899 he was employed as sales engineer by Best Fox & Company of Pittsburgh, piping

engineers and contractors, going to Philadelphia as their eastern representative in 1893. In 1899 he formed the partnership of W. K. Mitchell & Company, specializing in high pressure piping and its accessories. When this partnership was changed to a corporation in March 1909, Mr. Mitchell was elected president and treasurer. He continued actively in these offices up to the day of his death, which occurred on November 6, 1915.

AUGUSTUS JAY DU BOIS

Augustus Jay DuBois was born April 25, 1849. He was graduated from the Sheffield Scientific School in 1869, and was awarded the degree of civil engineer in 1870 and the degree of doctor of philosophy in 1873. Later he studied mechanics for two years at the Mining Academy in Freiburg, Saxony, and from 1875 to 1877 he was Professor of Civil Engineering and Mechanical Engineering at Lehigh University. In 1877 Professor DuBois was appointed Professor of Mechanical Engineering in the Sheffield Scientific School and in 1884 was transferred to the Professorship of Civil Engineering which position he occupied until his death.

Professor DuBois was the author of some of the best-known treatises on mechanics and stresses in the English language. His book on Graphic Statics, published in 1876, was largely instrumental in introducing to American engineers the graphic method of determining stresses in framed structures now so widely used. This was followed by his translations of Röntgen's Thermo-dynamics, Weyrauch's The Calculation of the Strength and Dimensions of Iron and Steel Construction, and Hydraulics and Hydraulic Motors and Heat, Steam and the Steam Engine from Röntgen's Mechanics. In 1883, his elaborate and original book on Strains in Framed Structures took its place as one of the most important contributions to engineering literature, being perhaps the first comprehensive treatment of the subject. A series of books on mechanics culminated in his Mechanics of Engineering published in 1901.

Professor DuBois was a member of the American Society of Civil Engineers, the American Institute of Mining Engineers, the Connecticut Society of Civil Engineers and the Society for the Promotion of Engineering Education. He died on October 19, 1915.

DWIGHT E. LYMAN

Dwight E. Lyman was born in Marshall, Oneida County, N. Y., on October 12, 1845. He was educated in the Deansville schools, and served an apprenticeship at the Willowvale Machine Works of Utica. Later he was employed for four years as superintendent and draughtsman by Keeney Bros. of Manchester, Conn. At the age of 20, he went to Hartford, and soon entered the employ of Asa S. Cook, serving as superintendent and mechanical engineer from 1875 to 1882. After this for one year he held a similar position with the Syracuse Screw Company, returning in 1883 to the Asa S. Cook Company as superintendent, the position he held at the time of his death. Mr. Lyman died at his home in Hartford on July 8, 1915.

JOHN E. WARREN

John E. Warren was born in Grafton, Mass., on October 7, 1840; but when he was still an infant his parents travelled West as pioneers and settled on a farm in Wisconsin, where the boy grew up. The short term country schools of the day

supplied all there were of his opportunities for schooling, except that he supplemented them afterward for a time by teaching, and then by entering Ripen Academy shortly before the outbreak of the Civil War. He promptly enlisted in the Union Artillery, and served with it through to the end.

Not long afterward he entered the employ of S. D. Warren & Co., makers of book paper. It was to this company at its plant at Cumberland Mills, Maine, that Mr. Warren devoted his business and professional service to the close of his life. He began as a mechanic, worked upward through various capacities, until in 1883 he was appointed Agent of the Mills, thus becoming the head and leader of its organization, the position which he retained for thirty-two years, up to his death. His interest turned naturally to engineering. The expansion of the mills, their growth which multiplied their capacity and value over four times during his administration of them, brought out the need for engineering services of high order.

Mr. Warren had been a member of the Society since 1886. He died on August 13, 1915.

PERSONALS

Gustave Eiffel, Hon. Mem. Am. Soc. M. E., has been appointed by the French Minister of War on the Consulting Committee of Experts on Military Aeronautics.

Charles E. Burgeon has resigned from the position of inspector of mechanical and electrical engineering with the Panama Canal, Washington, D. C., and has been appointed chief mechanical and electrical engineer with the Carbolite Chemical Company (Tennessee Copper Company), Copperhill, Tenn.

Thomas C. Shedd has resigned his position as instructor in mechanical engineering at Brown University, Providence, R. I., and has accepted a position with the Phoenix Bridge Company, Phoenixville, Pa., as draftsman.

Forrest W. Manker has become associated with the Moulton Engineering Corporation, Portland, Me. He was until recently connected with the B. F. Sturtevant Company as manager of their Hartford, Conn., office.

Cleon E. Phelps, formerly affiliated with the physical laboratory of the American Steel and Wire Company, Worcester, Mass., as mechanical engineer, has accepted a similar position with the American Optical Company, Southbridge, Mass.

Fred J. Beebert has resigned his position as instructor of mechanical engineering in the Texas Agricultural and Mechanical College, College Station, Texas, and has accepted the position of assistant examiner in the United States Patent Office, Washington, D. C.

The Lavigne Gear Company, Racine, Wis., one of the most extensive manufacturers of steering gears for pleasure and commercial vehicles in the United States, has been reorganized, its corporate name being changed to Lavine Gear Company. Mr. Herman A. Uiblein is president and treasurer of the company.

B. A. Behrend is the author of a brief article on Balanced Engineering which appears in the November issue of the Electric Journal.

John C. Parker has resigned as head of the engineering department of the Rochester Railway and Light Company, Rochester, N. Y., to accept the chair of electrical engineering at the University of Michigan, Ann Arbor, Mich.

Some Facts about Insulation by Henry A. Cozzens, Jr., is published in the November number of Electrical Age.

P. D. Wagoner was elected one of the directors of the Electric Vehicle Association of America at the October 18 and 19 convention in Cleveland.

Dr. Charles P. Steinmetz was elected, on November 2, president of the Common Council of the city of Schenectady, N. Y., on the ticket of the local socialistic party.

One of the many papers presented at the 23d annual meeting of the Naval Architects and Marine Engineers, November 18 and 19, in New York, was Some Comparisons Relating to Electric Propulsion of a Battleship by W. L. R. Emmet.

George K. Miltenberger, who has been stationed at Hickman, Ky., for several months in the capacity of local manager of the Public Service Company, which operates the city light and water plants, has been transferred to St. Louis.

A. J. Purinton, who was formerly manager of the East St. Louis, Ill., Light and Power Company, has accepted a position as general superintendent of the Atlantic City and Shore Railroad Company at Atlantic City, N. J.

Harold Carpenter, resident engineer of the Astoria Tunnel, Astoria Light, Heat and Power Company, New York, has contributed an article on Flooding and Recovery of the Astoria Tunnel to the November 1 issue of The Gas Age.

The Chamber of Commerce of Worcester, Mass., announces that an International Road Congress will be held in that city December 14 to 17, inclusive. The Massachusetts Highway Association and the Federal Government will cooperate with the local authorities in conducting the meeting. Among the engineers on the program for the Congress are Clifford Richardson, W. W. Crosby and Ira N. Hollis.

Nathan C. Johnson is a member of the advisory committee appointed by the United States Bureau of Standards to report upon the advantages of the use of hydrated lime in concrete.

Walter N. Polakov has resigned as superintendent of power of the New York, New Haven and Hartford Railroad, to engage in consulting practice. In the 18 months he had charge of the operation of the power plants of the New Haven, he effected a saving of 25 per cent in the cost of electric power.

Paul M. Lincoln has resigned from his position in the engineering department of the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., to devote his time to the manufacture of a meter which he has recently developed.

A. C. Dinkey, formerly president of the Carnegie Steel Company, Pittsburgh, Pa., now president of the Midvale Steel Company, Philadelphia, was tendered a farewell banquet by 60 operating officials of the Carnegie Company, October 30, at the Duquesne Club, Pittsburgh. Judge J. H. Reed presided.

Among those presenting addresses at the 19th annual convention of the National Founders' Association which was held at the Hotel Astor, New York, November 17 and 18, were M. W. Alexander and Albert G. Duncan.

Henry D. Sharpe, treasurer of the Brown and Sharpe Manufacturing Company, Providence, R. I., has given \$1000 toward a fund for a new home for the Providence Boys' Club, and also \$100 to the military aeroplane fund of Rhode Island.

Dr. John A. Brashear, President Am. Soc. M. E., has been appointed a delegate to the Pan-American Scientific Congress, which will meet in Washington, D. C., December 27 to January 7.

F. C. Trobridge has been elected president of the Manufacturers' Association of Hamilton, O., which has recently been organized. The object of the association is to bring about closer cooperation between employers and their em-

ployees and later on it is proposed to take up the matter of industrial education.

Frank A. Burr, formerly associated with the Spray Engineering Company, Boston, Mass., has been appointed instructor in power plant design at Pennsylvania State College.

Among those who took part in the addresses and discussions given at the conference on valuation held in Philadelphia, November 10 to 12, were: Morris Knowles, H. P. Gillette, Morris L. Cooke, Manager Am. Soc. M. E., John R. Freeman, Past President, Am. Soc. M. E., and Leonard Metcalf.

The November issue of Machinery which is largely devoted to safety and welfare work in manufacturing plants and selling organizations, contains a contribution by Forrest E. Cardullo on A Study of Safety and Welfare Work in Manufacturing and Selling Organizations. This article covers comprehensively safety and sanitation, housing of employees, cooperative organizations, profit-sharing systems, pensions, workmen's compensation, etc. Another article on this subject, entitled Safety Organizations of a Machine Shop, has been contributed by Luther D. Burlingame.

Frank O. Hoagland, works manager of the Union Metallic Cartridge Company, Bridgeport, Conn., has resigned the position to become assistant to B. M. W. Hanson, vice-president and works manager of the Pratt and Whitney Company, Hartford, Conn.

W. H. Winterrowd is the author of an article on First 4-8-2 Locomotives in Canada which appears in the November issue of the Mechanical Edition of the Railway Age Gazette.

A. L. Graburn, mechanical engineer of the Canadian Northern at Toronto, Ont., Canada, has been appointed assistant superintendent of rolling stock of the Eastern lines, with office at Toronto.

A. E. Ostrander has been appointed mechanical engineer of the American Car and Foundry Company, New York, succeeding John McE. Ames who recently resigned. Mr. Ostrander entered the service of the American Car and Foundry Company in 1903 and has been with the company continuously since that time.

Alan A. Wood, previously at the Providence, R. I., office of the Builders Iron Foundry as sales engineer in the venturi meter department, has become associated with their Pacific Coast agents, Norman B. Livermore of San Francisco and Los Angeles, in an engineering and sales capacity.

George H. Thorpe, until recently connected with the Millville Manufacturing Company, Millville, N. J., has accepted a position with John A. Stevens of Lowell, Mass., in the capacity of mechanical engineer.

H. O. Hem, formerly vice-president and superintendent of the H. N. Strait Manufacturing Company, Kansas City, Mo., has become a member of the engineering staff of the Toledo Scale Company, Toledo, O., in the capacity of consulting engineer.

Frank E. Watkins has become connected with the East Jersey Pipe Corporation, Paterson, N. J., as works manager. He was formerly associated with the Canadian Fairbanks-Morse Co., Ltd. of Toronto, Ontario, Canada.

Williams Alston Stevenson, former member of the Society and brother of A. A. Stevenson died on October 22. He was a graduate of Lehigh University of the class of 1890. Shortly after graduation he was made superintendent of the Stearns Manufacturing Company at Erie, Pa., and later superintendent of the Akron Plant of the Wellman-Seaver-Morgan Company. For a number of years previous to his death he was general manager of the Keystone Drop Forge Works at Chester, Pa.

J. Harland Billings has become associated with Johns Hopkins University as instructor in mechanical engineering.

STUDENT BRANCHES

ARMOUR INSTITUTE OF TECHNOLOGY

The opening meeting of the Armour Institute of Technology Student Branch was held on October 21. The meeting was in the form of a smoker to which the Junior students in mechanical engineering were invited. J. M. Byanskas, president of the branch, opened the meeting and outlined the policy for the coming year. Professor Gebhardt further discussed the plan which is to have more open discussion of important topics in which everyone takes part rather than have outside speakers.

CARNEGIE INSTITUTE OF TECHNOLOGY

The Student Branch of the Carnegie Institute of Technology held its first meeting of the school year on October 13. A. V. McNamara, president of the Machinists Union, spoke on the Relation that should exist between the Engineer and the Workmen in the Shop. He explained fully his position as leader of the movement that is making such a strenuous campaign to procure better wages, working hours and working conditions for the workmen. He declared himself to be strongly in favor of woman suffrage and expressed his opinion that that movement would be a great effect in producing a more desirable situation for workmen.

He then made an analysis of the relation between the workmen and the engineer. He showed how deplorable it is that many concerns maintain such a wide gap between the engineering department and the shops. In this connection, he pointed out with examples how the workman discovers and rectifies points that the engineer has not recognized, and which the workman cannot bring to the engineer's attention. Mr. McNamara called attention to the fact that all labor laws and improvements were brought about through the efforts of organized labor and that the engineers benefited just as much by them as those who had brought them about.

Following the address, there was an extended discussion upon open shops, the violation of labor laws by manufacturers, the bad effect of liquor and future prospects. Mr. McNamara expects that the next big movement in labor organization will be the consolidation of all of the unions.

CASE SCHOOL OF APPLIED SCIENCE

The first regular meeting of the Case School of Applied Science Student Branch was held on November 3. An illustrated address on The Electrification of Steam Roads Within the City Limits of Cleveland was given by E. P. Roberts, City Smoke Inspector. Mr. Roberts showed the importance of the problem of the electrification of the steam roads entering the city, since the citizens as well as the railroads are benefited by the increased prosperity of the city. He urged that no construction work should be allowed that would interfere with electrification whenever it should come. The advantages to the city that would come as a result of this step would be: first, the elimination of smoke and cinders; second, the increased traffic facilities; third, the possible suburban traffic and the improvement of the interurban. The areas affected by the smoke and cinders of the steam roads now in use represent 65 per cent of the entire city area, the affected zones being taken a thousand feet on either side of the track. Of this the cinder area is one fifth or 13 per cent of the city area. The greater part of the smoke is from switching engines which are used every day at the rate of 122 per hour, against 24 freight and 12 passenger locomotives per hour. The only method of smoke abatement possible with present systems is a change in equipment, which would be almost as expensive as electrification. In comparing the smoke emitted by locomotives and that from other sources, it was stated that black smoke is emitted much oftener and in larger quantities by the locomotives because of their construction, and the damage and annoyance due to smoke from locomotives is greater, since there is no high stack to carry up the smoke and fumes and so spread them out over large areas. The speaker discussed also the various systems of electrification available, including both direct and alternating current types using trolley wheel, pantograph or

third-rail contractors. He concluded by recommending careful and immediate consideration of this problem.

KANSAS STATE AGRICULTURAL COLLEGE

At a meeting of the Kansas State Agricultural College Student Branch held on November 4, A. Douglas was elected treasurer. Prof. G. B. McNair gave a talk on a Summer at the Westinghouse School for Teachers. J. H. Welsh read a paper on The Flour Mill at Kansas State Agricultural College. This is a model mill with all the modern equipment. Mr. Welsh told of the different processes the whole wheat must pass through before it is converted into flour, and described the arrangement of the machinery. Gabe Sellers reviewed an article on the Panama-Pacific International Exposition, which appeared in the October issue of The Journal, and J. J. Abernethy gave a talk on Clayton's Analysis, taken from a bulletin publication of the University of Illinois.

LEHIGH UNIVERSITY

The first meeting of the Lehigh University Student Branch was held on October 28 at which M. W. Kresge, '16, gave a talk on Military Engineering and L. Mardaga, '16, gave a talk on Surface Condensers. Mr. Kresge's talk dealt with his experiences with Engineer Companies at Student's Military Instruction Camps. He spoke briefly on field engineering, permanent fortifications, building of bridges and reading and drawing military maps. Mr. Mardaga spoke of condensers as connected with their use in the low pressure steam turbine. He also spoke of various apparatus used to produce the necessary vacuum and made a few remarks affecting the design of a surface condenser.

At a meeting on November 18 the best talk was by Prof. T. E. Butterfield, who spoke on "Diesel Engines." Professor Butterfield gave a brief history of the early development of these engines and also a general talk on the modern Diesel Engines illustrated by lantern slides.

The second speaker was J. M. Wells, '16, who described the trip of the Senior Mechanicals to the L. C. & N. Co.'s power plant at Hante on November 3.

J. M. Bausman, '16, spoke on "Schrapnel." He described manufacture of cases, schrapnel, and fuse, giving methods of pressing out cases and steel casings and finishing them. He also spoke on the contents of the steel casing and the workings and object of the fuse.

LELAND STANFORD, JR. UNIVERSITY

A business meeting of the Leland Stanford, Jr. University Student Branch was held on October 13, 1915. A large part of the meeting was devoted to a discussion of an amendment to the constitution whereby the dues of regular members shall be fixed at \$4.00 per year with an additional initiation fee of \$1.00 for new members. This will include a subscription to The Journal. This amendment will be put to a vote at the next meeting of the Branch.

At this meeting, J. L. Reynolds gave a very interesting talk on a plant for the extraction of gasoline from the "wet" natural gas which comes from wells producing oil with a paraffine base.

On October 27, thirty-six new members and Department members of the faculty were entertained at a smoker given at El Campo. Prof. W. F. Durand spoke on the advantages derived from the formation and work of Engineering Societies and Associations and the value of being connected or affiliated in some way with one of them.

Prof. G. H. Marx spoke on the initiative of the western student, and made a brief forecast of engineering activities for the next few years.

OHIO STATE UNIVERSITY

The Student Branch of the Ohio State University of American Society of Mechanical Engineers held a regular meeting on November 12 and were entertained at the home of Prof. and Mrs. Wm. F. Magruder.

Officers for the present semester were elected, and the programme for the year was discussed. It was decided to fea-

ture the meetings with talks from prominent engineers in the City of Columbus, and by papers written by members of the society.

The officers elected were as follows: Harold H. Brooks, president; Hugh V. Walhorn, vice-president; Ray Ellis, secretary; Maurice A. Nettleton, treasurer; Alex. F. Landefeld, sergeant-at-arms.

PENNSYLVANIA STATE COLLEGE

The regular monthly meeting of the Pennsylvania State College Student Branch was held on October 28. An illustrated lecture on the Panama Canal was given by H. P. Vail, who was employed in engineering work there during the past summer. Mr. Vail discussed the methods used in the construction of the canal and told of its operation as a waterway and of the improvements in sanitation which this Government has brought about. He also described the operation of the locks, explaining how the lock engineer, at a switchboard with a miniature layout of the system, has full control of a whole system of locks.

PURDUE UNIVERSITY

The first meeting of the Purdue University Student Branch, held on September 28, was a general get-together meeting, at which refreshments were served and talks were given by some of the professors.

At a meeting on October 12, William Borgard spoke on Electric Starting, Lighting and Ignition Systems and Their Failings.

At the third meeting of this Branch on October 26, an interesting talk was given by J. H. Enrick of the Senior Class on Automatic Adding Machines of the National Cash Register Company and also on the Company's Products, Organization and Welfare Work.

The idea for the cash register came to the originator on an ocean liner where he saw a revolution counter in use. The first register built counted only to a dollar, but great and rapid advancements have been made until now, it is a necessity in stores, both as a protection and an aid to the store manager against employees. Those of the latest design even furnish the customer with a receipt.

It is very essential that the cash register be designed and made very accurately and carefully. Often careless and inexperienced clerks operate the machines and certain parts have to be made heavier to withstand abuse. Above all, the machine must add correctly.

For the purpose of giving information, separate counters, separate transaction counters, customer counters, total counters and a variety of others are provided.

When Mr. Enrick had finished his talk on the cash registers, he was asked to tell about the welfare work which the Cash Register Company is doing for its employees. Apprentice courses are provided in every profession and trade found in the plant, and both day and evening classes of every kind are held. The lecture course is of a very high type and very often motion pictures illustrating the making of several kinds of manufactured products from rough material to the finished products are used in connection with the lecture. A library is also provided at a nominal cost to the readers. Athletic sports of all kinds are provided, including a country club for golf, and there is a well organized medical department, which is at the disposal of the employees for a small fee.

STATE UNIVERSITY OF KENTUCKY

At a meeting on September 24, the State University of Kentucky Student Branch was organized and the following officers were elected: Prof. F. P. Anderson, honorary chairman; J. D. Garrett, chairman; H. Worsham, vice-chairman; G. L. Cherry, secretary and treasurer. The chairman appointed T. C. Taylor chairman of the program committee, to be assisted by H. Worsham and H. E. Melton. The governing committee, composed of the officers and Professor Anderson as ex-officio member, was appointed.

At a meeting of the branch on October 29, N. C. Johnson's paper on the Hydration of Portland Cement, which appeared

in the September issue of The Journal, was discussed and illustrated by means of a projector. The other articles discussed were The Connors Creek Plant of the Detroit Edison Company and Graphical Tables for Calculating Reciprocating Compressors.

UNIVERSITY OF CALIFORNIA

At a meeting of the University of California Student Branch on October 26, a paper on Electric Arc and Percussive Welding was read by E. Eichler.

The following officers were elected at a meeting of the branch held August 31: C. Sebastian, chairman; M. Jones, vice-chairman; E. Eichler, secretary; H. Crow, treasurer.

UNIVERSITY OF CINCINNATI

Afternoon meetings of the University of Cincinnati Student Branch of the American Society of Mechanical Engineers were held October 7 and 28 for the purpose of explaining to the undergraduates, in Sections I and II, what the American Society of Mechanical Engineers is, its mission and work in the University. Talks were given by Prof. J. T. Faig, Prof. A. L. Jenkins, and C. Joerger. At the close of the meetings opportunity was given to the visitors to become members and forty men signed up.

On the afternoon of October 21 an open meeting was held, at which G. A. Monnett, formerly Chief Smoke Inspector of Chicago and Associate Editor of Power, was the speaker. His main topic was boilers, boiler settings and draft. A great many slides of different makes of boilers in their settings were shown, accompanied by tables showing the draft at different points in the setting. An interesting history of the development of the Chicago Standard Setting was given.

The first evening session and smoker was held October 29 at which Mr. Mittendorf, Assistant Chief Engineer of the Cincinnati Traction Co., spoke on tests of different coals, carried on by him, in order to determine the most economical coal for use in their power plants. The tests were run in their own plants, under ordinary working conditions, with the same draft, and with average firemen. The coal in Cincinnati comes from five or six different states, and the coal from each field is different from that of every other.

In order to show high over-all economy for a company, the coal must not be too expensive, must be adaptable to the present furnaces of the company, must show a high number of lb. of water evaporated per lb. of coal, must not be too high in ash, be free from clinker, and comparatively near for low freight rates.

A chart was shown, giving the results of these tests on the different kinds of coal. The advantages and disadvantages of the different coals were clearly shown.

UNIVERSITY OF COLORADO

At a meeting of the University of Colorado Student Branch on October 28, F. G. Gardner of the Department of Safety of the Interstate Commerce Commission read a paper on Mechanical Engineering on the Commission. This paper was the first of a series to be given by Mr. Gardner before the branch on the mechanical engineering side of the work of the commission. He discussed especially the legislation providing for safety devices and their development on railway rolling stock for the safety of the employees.

UNIVERSITY OF MAINE

The first regular meeting of the Student Branch of the University of Maine was held on September 28 at which the following officers were elected: J. M. Dodge, president; L. T. Rowley, vice-president; A. G. Smith, secretary and treasurer; Prof. C. H. Lekberg, honorary chairman, and L. E. Mulloney and G. C. Marble, executive committee.

UNIVERSITY OF MICHIGAN

The first regular meeting of the University of Michigan Student Branch was held on October 21, at which a special election was held. H. S. Manwaring resigned the secretaryship to become president of the branch. Frank C. Riecks

was elected vice-president and corresponding secretary; Gordon Smith, treasurer, and E. H. Merritt, recording secretary. Plans were discussed relative to the membership campaign and to holding a smoker for the purpose of stimulating interest in the branch. A motion was carried to raise the renewal rate for The Journal for graduates from \$2.00 to \$2.50 and to use the extra \$0.50 toward the support of the branch.

UNIVERSITY OF MINNESOTA

The second regular meeting of the University of Minnesota Student Branch was held on October 16. Lieut. E. P. Rollman of Battery F, First Field Artillery, M. N. G., spoke on the manufacture and use of shrapnel. After giving briefly the history of the development of this modern shell and describing the styles used by the European nations, he explained with the aid of two section models the construction and firing mechanism of standard United States shells.

UNIVERSITY OF MISSOURI

A meeting of the University of Missouri Student Branch was held on October 21. Professor W. J. Shephard of the Political Science department of the University of Missouri spoke on City Managership, a New Field for Engineers. In his talk, Professor Shephard said that our city governments and civic affairs were coming to be run as a business proposition, instead of under the corrupt and inefficient political rule of politicians.

The city's business must be organized and managed the same as that of any business firm or corporation. The corporation, which would adopt the practice of having its officers and employees elected, as is the case in the management of most cities, would soon go into bankruptcy on account of the inefficiency resulting. The same is true of the present election system in most cities it results in inefficiency, which in some instances has become so bad as to be brought forcibly to public attention throughout the whole country. The professional element is as necessary in the management of city government as in that of a corporation.

The speaker then showed by the use of a diagram how things are run under the present elective system, and how there is a lack of the responsibility element present of the worst sort. He then explained the new commission form of government for cities, and used as examples several of the cities of this country, which have adopted it, especially Dayton, Ohio. Dayton's system consists, first, of a commission of five men, who are elected by the people. They, in turn, appoint a city manager, in whose hands rests the active management of the city's affairs. It is not necessary for him to be a resident of the city at the time of his appointment; in fact, this is hardly ever the case. In most cases he is an engineer, and has charge of the hiring of the men under him. In other words, he is to the city as the chief engineer of a manufacturing company is to his company. Wherever this system has been tried, it has brought increased efficiency over that of the old system, for the lack of the responsibility element is no longer present, and each employee must be efficient to hold his job.

The speaker then outlined what he considered the three chief characteristics of the city manager, namely: *a* He should be a good all around engineer. Under this head, he mentioned some of the duties, classified under the various branches of engineering, which would fall to the city manager, especially in the small city. Under mechanical and electrical engineering he placed supervision of power and light plants, water works, heating and ventilation for public buildings, etc. Under civil and sanitary engineering he placed care and building of roads and pavements, sewerage systems, etc. *b* He must be a good business man. *c* He must have a thorough knowledge of men, and know how to manage them successfully. He pointed out how this position for the engineer, not only was one of dignity and honor and of good compensation, but it gave him an opportunity for the accomplishment of big things, and also that the number of cities using this form of management was increasing rapidly, thus enlarging this field of engineering activity. So he urged those who were students in mechanical engineering to

consider seriously the advantages and opportunities offered in this field.

The following officers were elected for the first semester 1915-16: J. C. Squires, president; Fred P. Hutchison, secretary-treasurer; Ralph Coatsworth, corresponding secretary; Professor J. R. Wharton, Troy Russel and F. Nelson Westcott, Governing Board.

UNIVERSITY OF NEBRASKA

A meeting of the University of Nebraska Student Branch was held on October 2. Practically the entire evening was devoted to a discussion of several practical problems of interest to the engineer in general. These problems were sent in by outside engineers in practical work. Professor Hoffman announced the problem by sketch and explanation. The discussion was very enthusiastically entered into.

YALE UNIVERSITY

At a meeting of the Yale University Student Branch held on October 5, the following officers were elected: E. B. Ripley, chairman; W. B. Day, secretary, and W. C. Keeley, treasurer.

EMPLOYMENT BULLETIN

The Secretary considers it a special obligation and pleasant duty to be the medium of assisting members to secure positions, and is pleased to receive requests both for positions and for men. Copy for the Bulletin must be in hand before the 15th of the month.

POSITIONS AVAILABLE

The Society acts only as a "clearing house" in these matters and is not responsible where firms do not answer. Stamps should be enclosed for forwarding applications.

69 Representatives wanted in all the leading cities for a line of vacuum heating specialties. Apply through Society.

108 Large European concern wants superintendent thoroughly posted in the manufacture of rubber shoes, technical and surgical articles, covering for rollers, tubes of all kinds, balls, toys and similar articles made of rubber.

116 Technically educated engineer wanted in the further development of plans for constructing an improved rock-tunneling machine now in operation in New York. Will require engineer having sufficient financial backing to be able to devote part time to this proposition until placed upon self-sustaining basis and before any considerable return can be expected.

136 High grade designers wanted by Pennsylvania concern. Men needed with drawing office experience, particularly on heavy machine tools and similar machinery.

140 Engineer, or designer and draftsman on hydraulic press work. Man experienced in hydraulics, capable of making designs and drawings for special presses as veneer, binder board, hot plate presses, etc. Location, Pennsylvania.

190 Foremen experienced in the manufacture of rubber articles for European concern as listed in position 108.

192 Production engineer or mechanical superintendent for pulp mill; man with technical training and practical experience, familiar with modern methods of machine shop management, etc. Name confidential. Apply by letter.

205 Draftsman experienced in the design of bending rolls and who has had actual work in this line. Location, Southern States.

282 Machinery salesman, preferably one experienced in line of refrigerating machinery. Location, Philadelphia, with occasional trips within one hundred miles.

313 Detail draftsman for chemical work; must have some knowledge of chemistry. Apply by letter. Location, New York.

314 Draftsman for wood factory building; must be familiar with piping and belt drives. Apply by letter. Location, New York.

323 Live company engaged in manufacture of projectiles want high grade engineers for important positions. Prefer men with similar experience. Name confidential.

324 Three or four competent men to act as foremen in manufacturing plant in assembling of mechanical parts of munitions. Salary \$100 to \$125 a month. Location, New Jersey.

320 Young mechanical engineer with one or two years' experience in shop practice, wanted for drafting and testing work with concern doing general foundry and light machine shop work. Testing work will be mainly on power and heat transmission and the economical operation of mechanical devices in the shops, and for the first few months drafting out the general arrangement of the foundry, shops and apparatus. Give references and salary expected. Location, Middle West.

333 Machinist, pattern maker, draftsman and designer wanted as shop assistant for New Jersey concern. Salary to start, \$30.

336 Draftsman with at least five years' experience in machine design, pipe work, etc. Salary, \$125 month. Location, New Jersey. In applying state record of positions held and dates.

345 Massachusetts manufacturer of small electrical apparatus in quantities, requires the services of an assistant purchasing engineer for inspection of incoming materials; requires thorough familiarity with insulating and composition casting materials with practical knowledge of metal working and similar machinery. In applying give details covering age, nationality, education, practical experience, salary.

352 Machine shop foreman experienced in the building and manufacture of metal lathes. Salary, \$2500 or more, depending on experience and ability to produce results. Location, Middle West.

353 Draftsman and one checker on open hearth, Bessemer and power plant work. In applying give full details of experience, references and salary expected. Location, Chicago.

356 Night superintendent thoroughly experienced in machine shop practice as applied to the manufacture of automobile parts and fairly well versed in the principles of efficiency management. Location, Chicago.

357 Salesman experienced in marketing high grade hot rolled electric and open hearth steel specialties; one having sufficient knowledge and information to post operation in securing proper tonnage for mills. In applying state age, experience and salary expected.

358 Draftsman experienced in design of steel pulleys; must be accurate, rapid and industrious. Salary about \$25. State age, experience, previous employers and references. Location, Massachusetts.

362 Recent engineering graduate as research assistant in engineering library. Knowledge German and French essential. Location, New York. Library experience desirable, but not necessary.

365 Foreman for machine shop. Prefer one who has had eight or ten years' experience in gas engines or automobile motors, in modern factories and who is familiar with modern practices, who can get out production and understands thoroughly the handling of modern jigs and equipment. In applying give experience, salary desired to start, and references. Location, Ohio.

366 High grade draftsman competent to take charge of a number of men and do own calculating, with at least ten years' experience in drafting room. Location, Pennsylvania.

369 Plant engineer or millwright as superintendent for a plant employing approximately one thousand men; technically trained man preferred with several years experience in plant maintenance, development of ideas, erection of new buildings, etc. Record must show successful previous con-

nections. Salary proportionate to experience and ability. Location, Middle West.

370 Young graduate engineer as salesman for water purification apparatus, filters and softeners for industrial and municipal supplies in New York and vicinity. Preference given to one who has good working knowledge of inorganic chemistry and with selling experience. In applying give full details of age, education, experience and salary.

372 Young engineer about thirty years of age who has studied efficiency work and with some experience in organizations doing such work. Excellent opportunity for industrious, intelligent and tactful man to get results without affecting present organization and introducing too much "system"; salary, \$1500 to \$2000 to start. Location, Connecticut.

376 Technical graduate, with one or two years' experience; to act as an assistant in steam engineering and general power work. State qualifications in detail and salary expected. Location, Cleveland, Ohio.

381 Experienced machine tool designer, prefer man with planer experience. In applying furnish records, salary expected and when ready to report for duty. Location, New Jersey.

384 Expert on power plant work and equipment with valuable patents in that line, strong personality, excellent executive and salesman, desires to invest several thousand dollars in established engineering enterprise or form partnership with consulting engineer. Advertiser is also ready to act as consulting engineer to engineering concerns.

385 Draftsman and assistant engineers familiar with mill construction, power plant design and industrial engineering. Apply by letter, stating experience, education, when and where born, nationality of parents, married or single, former employers, salary expected, and when available.

386 Tool designer, accustomed to heavy machine tool work. Location, Illinois.

387 Assistant factory superintendent; technical graduate and man with experience in handling men and in the production of small accurate work. Salary, \$2500 to \$3000 to start, but dependent largely on ability. Location, Connecticut.

388 Capable tool designer who is resourceful and can follow his own work through to completion. Man with practical shop experience as well as technical education. Location, Connecticut.

390 Designers and detailers for drawing room in Boston doing printing press work. Printing press experience not essential. Applicants must be careful, industrious and have sound mechanical knowledge.

391 Mechanical draftsman with blast furnace and rolling mill experience. Location, Pennsylvania.

394 Superintendent, machine tools, foundry and machine shop, employing 900 men. Prefer good executive to a mechanical expert; must have shown ability in factory management. Salary not limited. Apply by letter. Name confidential.

397 Competent shop superintendent or general machine shop foreman. Salary, \$150 to \$200 a month, according to ability. Location, Ontario, Canada.

MEN AVAILABLE

L-347 Member, age 35, technical training in mechanical, electrical and building construction course, Lowell Institute, Boston. Three years experience in drafting room and machine shop on steam pump work; ten years experience in charge of drafting room and design of steam boilers and steel plant work in Massachusetts, desires permanent position with opportunity for advancement with manufacturing concern, large central station power company or consulting engineer. Location preferably Boston.

L-348 Sales engineer with technical education and over five years practical experience (past four years with one concern), would like to communicate with first class manufacturing concern having an opening as manager or assistant. At present employed.

L-349 Technical graduate, age 28, dependable, progressive with thorough, practical shop and engineering department experience, desires position as assistant to superintendent.

L-350 Associate-member, M. E., age 38, expert in interchangeable manufacturing, sheet metal stamping and evolution of shapes; economic production of duplicate parts, light mechanical devices and machinery. National reputation as mechanical expert and consulting engineer, author of numerous standard mechanical text books; developer and perfecter of machines and devices for commercial efficiency and success, desires position as production engineer where ability to eliminate costs, operations and intricate mechanisms and effect maximum efficiency and output at minimum cost will earn \$4000 per year, and more when results justify increase.

L-351 Ordnance engineer, member, age 32, married, M. E., degree 1913, several years civilian employee of Ordnance Department, U. S. Army, experienced in design of various kinds of ordnance including guns, carriages, ammunition vehicles, ammunition and familiar with the design of machine rifles and their equipment, desires position in connection with the design and manufacture of ordnance.

L-352 Member, with experience in the design of locomotives and cars, and one who has made a study of the organization and handling of men and also expert examination of properties in order to bring them to a high point of efficiency, desires position as manager of large manufacturing concern.

L-353 General manager or superintendent of foundry, has had charge of some of the leading foundries of the country, capable of handling any foundry proposition, desires position.

L-354 Mechanical engineer, Stevens graduate, 1900, twelve years' mechanical superintendent, three years assistant manager, of large manufacturing plant; thoroughly versed in design and construction of mill buildings, installations and economical operation of electrical generators and motors, engines, boilers and manufacturing machinery, desires position. Vicinity of New York preferred.

L-355 Mechanical engineer, broad shop and office experience, expert in the manufacture of shrapnel and all sizes of high explosive shells, desires opening as organizer and manager of concern taking up shell work, or allied parts.

L-356 Mechanical engineer, age 33, married, graduate in mechanical engineering, eleven years' experience, four years as mechanical engineer in charge of design and construction of various machinery, has had experience in machine shop, inspection and testing, desires position as mechanical engineer, superintendent, chief draftsman or other executive position.

L-357 Junior, age 30, married, M. E. graduate, six years' designing experience in automobiles, motor trucks, production tools, small punch and die work, a large variety of special and semi-automatic machinery and inspection gages; possessed of sound originality and knowledge of tool room practice, careful and systematic, desires position in efficiency or production department.

L-358 Junior member, technical graduate, wishes connection with manufacturing firm which is about to make extensive addition to its plant as a representative of the owner to supervise the work and layout of the contractor, engagement to terminate when contract is finished to the satisfaction of the owner.

L-359 Practical and educated man of broad experience in manufacturing duplicate parts on the interchangeable basis, would like to hear from reliable firms with a view to securing the services of a live up-to-date executive, especially

trained in the handling of difficult problems on all kinds of automatic machines and the die-casting of duplicate parts.

L-360 Technical graduate, wide experience as railway mechanical engineer, machinist, motive power draftsman and mechanical engineer, desires position along these lines, or one as mechanical inspector, assistant superintendent motive power, or assistant to general manager. Location, immaterial.

L-361 Technical graduate, age 31, nine years' broad experience in designing, manufacturing and testing special machinery, also delicate instrument work, thoroughly familiar with drawing office methods, pattern, foundry and machine shop practice, good executive, can handle correspondence, and draw up specifications, desires position. Location, immaterial.

L-362 Member, specializing in the installation of scientific management, seeks engagements in that line. Speaks Spanish fluently and would accept engagements in Latin America for the investigation of the efficiency and possibilities of improvement of enterprises, or would do betterment work.

L-363 M. E. graduate, two years general work and three and one half years' experience handling men, at present department foreman in large ammunition plant, desires responsible position with manufacturer of metal products.

L-364 Two young engineers, graduates M. E. and E. E., four years' sales and management experience, are open for attractive sales or manufacturing proposition. Want territorial agency, preferably New England for live-wire commodity. Extensive acquaintance among manufacturers. Capital investment possible.

L-365 Member, age 37, manufacturing plant construction and operating experience, also purchasing and structural steel estimating, two years as mechanical engineer with packing house, now engineer and traveling superintendent for a group of cotton oil mills. Salary \$3600. No traveling.

L-366 Junior member, seven years' experience in design of oil engines, jigs, tools, power plant details, and as executive in charge of a small food project, desires connection with engineering or manufacturing concern.

L-367 Associate-member, graduate engineer, broad selling experience in steam specialty line, covering territorial representation, special representation in building up agent's territories, sales management, sales distribution and advertising, also some experience in manufacturing, desires position with concern in need of such a man to grow up with the business.

L-368 Member, technical graduate, ten years' experience in general engineering work with prominent consulting engineers, accustomed to responsibility and control, familiar with inspection and tests of materials and power equipment, fuel combustion, power production, plans and specifications, twelve years' experience in machine shop work, desires executive position with responsible firm or consulting engineer.

L-369 Works manager, age 40, with large and long established company manufacturing power equipment, twenty-two years general shop experience, having handled men for fifteen years, experienced in large production, having supervised from fifteen hundred to eighteen hundred men, desires to make a change.

L-370 Student member, M.E. graduate, Columbia 1915, with shop drafting room and power plant experience, employed at present, but desires to connect with an engineering or manufacturing concern in or about New York, with whom there is a chance for advancement.

L-371 Gas engine detailer, graduate mechanical engineer, 1911, age 26, shop experience erecting and testing engines and tractors, operating in field, detailing, wants further experimental drafting. Location, Middle West.

L-372 Member, South American, reliable, capable sales engineer, five years with present connection prominent Eastern jobbing house, sales, conversant with Spanish language

and understands the Latin people, have had considerable business experience and can efficiently represent manufacturers, hardware, mill and railroad supplies, agricultural or machinery lines, desires correspondence from concerns interested in developing South American business. Can furnish unquestionable references.

L-373 Member, graduate M.I.T., age 32, with special experience in power station work, heating and ventilating systems and electrical work, both in design and installation, desires position as mechanical engineer or superintendent of construction.

L-374 Mechanical engineer, graduate Columbia 1912, experienced in design and construction work, desires permanent position, preferably in sales or where there is a chance to work into sales or commercial end of business. Location, immaterial. Salary, \$1500.

L-375 Junior member, mechanical graduate 1913, one year shop work, eighteen months drafting and designing, four months in responsible charge of laying water mains, desires position with construction contractor. Available in December.

L-376 Manufacturer's agent, experienced and competent, invites correspondence and investigation by those who desire a live representation in Chicago district.

L-377 Graduate mechanical engineer, twenty years' active experience, rising from shop and drafting room to chief engineer in charge of design, construction, maintenance and operation of large industry; long experience in steel works, also in heavy and medium heavy machinery design and operation, purchasing and inspection. Aggressive executive, thorough, economical and particularly successful in overcoming troubles and improving operating conditions as well as working out original problems of design and carrying through to a finish a complete enterprise, desires to change after long service in present position. Terms moderate.

L-378 Member, technical graduate, age 37, married, eleven years' practical experience in U. S. and abroad in general power station design, engineering and construction, also five years' experience in engineering, administrative and sales department of manufacturing corporations, desires to make connection with manufacturing company as purchasing engineer or executive position. Would eventually be able to invest some capital in right proposition. Has thorough knowledge of German, working knowledge of French. At present employed. Location preferred on Pacific Coast.

L-379 Associate member, Lehigh University graduate in mechanical engineering, with eighteen years' varied experience in mechanical, electrical and civil engineering lines, involving design, supervision and direct charge of construction work, plant operation, purchasing, reports, etc., all in connection with electric railways, lighting plants, power and industrial plants, wishes an executive position as manager, superintendent, or sales engineer, with larger field and responsibility. At present employed. Southern location preferred.

L-380 Junior member, age 26, technical graduate 1912, two years in testing department of large eastern electrical manufacturer, and experience with contracting concern, desires position with company operating power plants and street railways in middle west. Salary, \$1200. At present employed.

L-381 Member, experienced in the manufacture of guns, small tools and machinery desires change. Highly successful as an executive in getting quality goods at low cost. Now superintendent of factory building high grade machinery.

L-382 Man of wide practical experience in inventing, designing and constructing special machinery would like a position along these lines. Salary, \$3000.

L-383 Member experienced in power plant and shop work, responsible charge of estimating, production and costs in large concerns, some teaching experience; five years active participation in welfare and social work in industrial plants.

ACCESSIONS TO THE LIBRARY

This list includes only accessions to the library of this Society. Lists of accessions to the libraries of the A.I.E.E. and A.I.M.E. can be secured upon request from Calvin W. Rice, Secretary of Am. Soc. M. E.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Report of the Committee to formulate standard specifications for the construction of steam boilers and other pressure vessels and for their care in service known as the Boiler Code Committee. Rules for the Construction of Stationary Boilers and for allowable working pressures. ed. 1914. *New York, 1915.* Gift of A. M. S. M. E.

Condensed catalogue of mechanical equipment, 1915. *New York, 1915.* Gift of A. S. M. E.

BALL BEARINGS, B. D. Gray and H. Wicklund. Presented by B. D. Gray, April 14, 1915, before Electric Vehicle Association of America, at Philadelphia. Gift of Hess Bright Mfg. Co.

CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE. Growth of Internationalism in Japan. Publication no. 6. *Washington, 1915.* Gift of Carnegie Endowment for International Peace.

CONVERSION CHART, Mort R. Wolford and C. K. Carpenter, *New York, J. Wiley & Sons, 1915.* Gift of publishers. Price \$.25 net.

A chart 12x34 on logarithmic coordinate paper. By means of this chart, conversions between units of work, pressure, time or temperature, as well as surface, area, weight or mass conversions for all common units, including metric, may be quickly made. W. P. C.

COOLING PONDS FOR CONDENSING ENGINES, L. H. Parker. *Boston, 1915.* Gift of Spray Engineering Company.

ELEMENTARY LESSONS IN ELECTRICITY AND MAGNETISM, S. P. Thompson, ed. 7. *New York, 1915.* Gift of Macmillan Company.

Professor Thompson has completely revised the book for this edition. There is a new chapter on Wireless Telegraphy, and another on the modern conception of the Electron. W. P. C.

THE EVILS OF GOVERNMENT OWNERSHIP, J. Bourne, Jr. Gift of American Electric Railway Association.

HIGH EXPLOSIVE SHELLS. A reprint of important articles presented in the American Machinist, from June to October, 1915. Gift of American Machinist.

HYDRO-ELECTRIC DEVELOPMENT OF THE COHOES COMPANY, Cohoes, N. Y. Reprinted from General Electric Review. Gift of Sanderson & Porter.

INTERNATIONAL IRRIGATION CONGRESS. Official proceedings of the 21st, 1914. *Ottawa, 1915.* Gift of Canada. Department of the Interior-Irrigation Branch.

MACHINE DESIGN, A. W. Smith and G. H. Marx. ed. 4. *New York, J. Wiley & Sons, 1915.* Gift of publishers. Price \$3.00 net.

The text has been thoroughly revised in this edition, and the results of new investigations of machine elements have been included. W. P. C.
